PARA-AMIDOPHENOL.

A new developer naturally takes some time to find its proper place in the estimation of photographers, for, whatever its intrinsic qualities, it is pretty certain to possess some peculiarities that have to be mastered before a real judgment can be arrived at as to its value. In the earlier days of gelatine plates there was a choice of two developers, each equally novel to the majority of photographers, who very largely gave their preference to the one which most resembled in its behaviour what they had been accustomed to with wet plates. Ferrous oxalate, being practically a "one-solution" developer, performing its task in a single operation, much in the same manner as the familiar solution of sulphate of iron and acetic acid, and moreover yielding an image much more of the wet-plate type, took the fancy of the old wet-plate worker sooner than alkaline pyro, with its more complicated method of working, simply because the latter required more learning; but, as the knowledge of how to use pyro increased, and the functions of the different constituents of the developer began to be understood, its superior capabilities were recognised, with the result that it soon displaced ferrous oxalate, except for positive work.

Hydroquinone, and subsequently eikonogen, next came into the field, and, after figuring as chemical novelties for a while, gradually became the subject of serious trial, giving rise to endless controversy as to their real value, and even at the present time neither can be truly said to have taken a fixed position. Though each of them may have numerous friends and admirers, it will scarcely be denied that pyro still remains the general favourite, and that in spite of drawbacks from which the younger rivals are free.

The newest addition to our list of developing agents, para-amidophenol, although it has been before the public now for some time, has not yet passed out of the novelty stage, and it will in all probability be long yet ere it secures any very general adoption. All the accounts of its behaviour have been, so far as we are aware, entirely favourable, and in many cases even enthusiastic; but this is generally the case, for the experimentalist is prone to go into raptures over any new thing that proves tolerably successful at the outset without waiting to discover its shortcomings, or measure it comparatively with pre-existing methods.

In saying this we do not for a moment intend to decry the new agent, nor to suggest that its praises have been over-sung. On the contrary, we are bound to confess that para-amidophenol starts with a better record than either of its immediate predecessors, so far as the quality of its results and its general adaptability are concerned. But the question to be decided (and that can only come with time) is, does it offer any real advantage over pyro, hydroquinone, and eikonogen? Its sponsors claim it to be the most powerful developer extant, which possibly it may be, and yet without satisfying every requirement; but, at any rate, there must be reckoned on the other side of the account its insolubility, which forms a serious hindrance to its general adoption.

We have purposely deferred expressing any definite opinion on the new agent, samples of which were sent to us some time ago by Messrs. Becker & Co., until we had had opportunities of giving it a pretty extended trial, and, though even now we can scarcely consider ourselves in a position to arrive at a decisive judgment, we can at least indicate some of the most noticeable features in its character.

Without going into ecstasies on the matter, we may at once say that first impressions of para-amidophenol are decidedly favourable, so far, at least, as its developing action is concerned. It is rapid in its action, clean in working, gives an image of excellent quality, and seems to be peculiarly elastic in its capabilities, though precisely the same may be said of pyro, and perhaps of other developers.

But the first drawback is found in its comparative insolubility, which renders it almost, if not absolutely, compulsory that it be employed as a one-solution developer, as, without the alkali, it is practically impossible to get sufficient dissolved to form a useful stock solution. There is, perhaps, no reason why we should object to a developer which is complete in a single solution if it does its work as well as another; but it is difficult to believe that, under such circumstances, there is as much control over the action, as it progresses, as when, by the addition of alkali or restrainer, deficiencies or errors in the exposure may be rectified so soon as they become apparent.

It is true that in the old wet-plate days the developer was a single solution, and exposures had to be toned with something approaching accuracy, in order to ensure success, and possibly the general quality of the work turned out was none the worse for that; but, under the new *régime* of dry plates, the system of "rational development," as it has been called, *i.e.*, the modification of the developer to suit the image as it progresses has always found greater favour than the application of a complete solution, whether mixed at the moment or kept in stock. Even with ferrous oxalate, originally a one-solution developer pure and simple, the practice of modifying the solution as the plate seemed to require it gradually crept in, and, so long as our sensitive films continue to possess the latitude that permits this patching up of a wrong exposure, so long will the so-called rational development be resorted to.

For a single solution developer para-amidophenol behaves remarkably well. It keeps well, remaining colourless for a very long period; some that we prepared upwards of three months ago is apparently unchanged, and so far as we can judge retains its energy intact. Its developing action is rapid and

the case, varnishing would be a very great improvement, a benzol varnish, used without heat, may be applied with safety and advantage, the plate being first dusted with scrupulous care. A singular point may here be mentioned: a reversed picture — that is, one in which the right hand appears to be the left, and so on—is never satisfactory; hence all the requests to make the picture "face the other way about" must be met with a refusal, otherwise the copy will be a failure. This remark applies to all kinds of photographs. But the difficulty about glass pictures is that they usually are reversed, the film side being generally that exposed to view. Our advice here is not to bring the picture back to nature (which may be done by copying from the back, if it be upon clear, colourless glass), unless it be a very recent one, for the eye has become accustomed to the aspect of the glass picture, and a reversal will disappoint. We could add very much upon this aspect of portraiture, but must not here do so, to avoid making our articles wanting in conciseness. We must again say that the best results in copying these photographs are obtained by wet collodion, though careful attention to exposure and development will enable very good results to be produced by dry plates.

In fixing up the picture for copying, the same care is needed to obviate reflections that we have indicated with Daguerreotypes, especially as regards the front of the camera; but a more all-round light may be used. Those who have not copied glass pictures will be astonished at the plucky, vigorous negatives obtainable even when the enlargement is to several diameters.

From the ninth *Annual Report of the Committee on Indexing Chemical Literature* we find one bibliography which would be most useful to photographers. It is entitled *A Bibliography of the Chemical Influence of Light*, by Alfred Tuckerman. It is in the Smithsonian Miscellaneous Collection, numbered 785, published at Washington, in 1891, and consists of twenty-two pages 8vo. Great interest is aroused in the chemical world by recent investigations upon a newly discovered gaseous compound of iron. Finely divided iron is heated in a stream of carbonic oxide, the product, after a long operation, being the new compound we speak of, which is termed ferro-penta-carbonyl. It is a light amber-coloured liquid, which may be distilled without decomposition, and has a specific gravity of 1·44. Its interest to photographers lies in the fact that it is sensitive to light. Kept in the dark it is perfectly stable, but when exposed to light an important change takes place, gold-coloured crystals rapidly form in it, which, upon analysis, are found to consist of a second iron carbonyl. They are insoluble in ordinary solvents but when heated to 80° C. they decompose.

One of the latest uses of chloride of gold, but which we yet think is not likely to enhance its value to photographers, is an extremely remarkable one, being no less than as a cure for dipsomania!

Most scientific photographers are aware of the difficulty of obtaining a trustworthy standard of light for comparative experiments, We described, at the time it was first adopted by a scientific committee, the melting platinum standard, which is quite impracticable for photographic use. Then we have Mr. Vernon Harcourt's pentane lamp, and lastly the authorised standard of the Board of Trade—the "standard candle." For a long time past it has been seen that the latter is open to serious objection, in that it is far from a constant illuminant, quite apart from the statement, which we believe to be correct, that special candles are made, which, apparently legal, are so made as to give indications favourable to the gas-manufacturers. Such a condition of affairs has led the Board to appoint a committee to consider what the standard light for testing the gas supply of London should be. The South London Gas Company, of which Mr. G. Livesey is Chairman, have undertaken to pay the whole of the expenses, and the committee will shortly be formed. It will consist of two members of the County Council, one appointed by the City Corporation, three by the London Gas Company, together with three gas referees and two independent scientific men. Dr. E. Frankland, F.R.S., and Mr. Dibdin, the Council's chemist, will represent the London County Council. Pending the report of this Committee, the Council has deferred action in the direction of obtaining legislation for a more exact standard of light.

It is quite evident that, if a practicable and reliable standard can be devised, it will be of considerable value to photographers; for, although it goes without saying that a light standard is not necessarily a standard of actinism, its advent will be hailed with satisfaction, if only on the principle of half a loaf being better than no bread.

Writing on this topic, a correspondent suggests to us the advisability of designing a suitable burner for burning the ordinary ether of commerce, which can be obtained practically pure at a cost which would be merely nominal.

Mr. W. T. Suffolk writes to the *Chemical News* on the subject of the new methylated spirit, and makes a suggestion of a very practical nature, in which we are sure many photographers and photographic manufacturers will heartily join. "By the new order," says Mr. Suffolk, "histologists are deprived of their most valuable reagent. Alcohol in histology, like sulphuric acid in chemistry, is the key to most of the work, and a heavy duty on either would bring work to a standstill. Among the societies whose members are affected, besides the Royal Microscopical, are the Chemical, Photographic, Linnean, Zoological, &c. Hospitals, large museums, and medical schools are able to obtain quantities of five gallons and upwards of the old kind of spirit; but small laboratories, and the whole race of amateurs must either leave off work or pay the duty of ten shillings and sixpence per gallon. Truly 'endowment of research' with a vengeance."

Mr. Suffolk brought the matter before the Council of the Royal Microscopical Society, and that Society rightly considered that other societies might take united action in the matter, and bring pressure to bear upon the Inland Revenue. We should hope, with Mr. Suffolk, that this body is ignorant of the mischief it is doing. So far, no photographic society has moved in the matter of a protest, but Mr. Suffolk's invitation will surely not go unheeded. Some weeks ago it was mentioned at a meeting of the London and Provincial, but no action was taken. With so much energy at command at 50, Great Russell-street, we suggest that this is a fitting opportunity for the Photographic Society of Great Britain to approach the Somerset House authorities.

Now that the subject is engaging popular attention, it is reasonable to expect that a decided impetus will be given to the provision of other agents for altering the tones of bromide prints besides uranium. Mr. A. Haddon is already in the field with some experiments in this direction. He has just allowed us to inspect a bromide print having a far from disagreeable brown colour, which he informs us was produced by treating the picture with a solution of a salt of copper alone. When some necessary further experiments in the improvement of the method are completed, Mr. Haddon will probably enlighten us as to the identity of the particular salt which has the valuable property of reacting with metallic silver, thus improving the tones of developed bromide prints.

A reversing eyepiece for the stereoscope has been patented by Mr. Birt Acres. The eye-tube is necessarily somewhat longer than is usual in oculars for the stereoscope, because it has to contain four lenses, each separated from the other by a certain space. The advantage of such eyepieces is in its being possible to print a transparency by superposition from the uncut negative, and then to examine it in a stereoscope thus fitted, the effect of solidity being given. This was done long years ago by means of reversing prisms, but Mr. Acres' method is distinctly different.

Our sprightly morning contemporary, the *Daily Chronicle*, recently treated its readers to a lengthy and solemn review of Mr. W. E. Woodbury's book on the gelatino-chloride-of-silver printing process, which, however, was less of a review of the book than a critical examination, more or less trustworthy, of the process itself, and the various commercial brands of paper on sale. We congratulate Mr. Blackie and the Blackfriars Photographic Company upon the laudatory notice which celerotype is fortunate enough to obtain from such an impartial authority. But we are curious to learn the reason of our contemporary's dismissal of the Ilford printing-out paper in the damnation-with-faint-praise vein which the writer thinks fit to adopt. Aside of these peculiarities, the *Chronicle* review contains a great deal of information which will be new, if not instructive, to photographers, and on that ground, to quote the old phrase, it is well worthy of perusal. It is also maladroitly humorous, which, for the reputation of the *Chronicle*, we sincerely trust is attributable to the festiveness of the season, and nothing more. As our readers will see from the letters in another part of the Journal, the Britannia Works Company are unable to enter into a kind of humour of which they are the innocent victims, and they have properly entered a protest against some of our contemporary's remarks.

Mr. Frank Hars was kind enough recently to exhibit to us a photographic relic of possibly the highest historical interest. This was a document in the handwriting of Daguerre, giving instructions for the working of the process with which his name will be for ever identified. The document is neither signed nor dated, although there is evidence in existence to show that it is probably a genuine production of Daguerre's, from whom it was said to have been received by Mr. L. Loewe, private secretary to the late Sir Moses Montefiore, in the year 1840. If any one has a letter written and signed by Daguerre, Mr. Hars would be glad of a photograph of it, in order that the writing might be compared with that of the document referred to.

AMERICAN NOTES AND NEWS.

From a notice in the *Photographic Times* we gather that the *American Annual* for 1892 is published. Although we have not yet seen it, the goodly array of names of contributors given leaves no doubt for believing it will prove an excellent number.

We learn that a lens with a twenty-four-inch aperture, and focal length of eleven feet, is to be fitted to the photo-telescope for Harvard University now being made by Alvan Clark, & Sons. It is said that it will be the finest instrument of its kind ever constructed.

The death of a well-known Canadian photographer (Mr. William Notman, of Montreal) is announced as having taken place on November 25. Mr. Notman was a Scotchman, having been born in Paisley in 1826. In 1856 he went to Montreal, where he entered into the "dry-goods" business, but soon gave it up in favour of photography, in which he had been an amateur previous to leaving Scotland. He soon acquired great distinction. Branch businesses were established in Boston, Halifax (N.S.), and New York under the management of his sons. He was much respected wherever known.

Not only to many of his own compatriots, but to not a few self-styled inventors on this side of the Atlantic, do we commend for imitation a most refreshing piece of honesty which saw the light a little while ago at a meeting of the Photographic Society of Philadelphia. Here is its record: "Mr. James Wilson exhibited a new shutter for instantaneous or time work. It was copied from an English invention, known as the Sargent shutter." Honour to thee, Mr. James Wilson, for that acknowledgment; but how, pray, can a "copied" shutter be "new?" Never mind. You own that it was copied, and you deserve a decoration for the admission. "*O, si sic omnes!*"

Mr. A. H. Calderwood, in *Anthony's Bulletin*, recommends the following method of stripping negatives for reversing:—Coat with rubber turning solution (para gum dissolved in benzole to the thickness of collodion) and allow to set, which is shown by the disappearance of the glossy surface. Next coat with a thin, plain collodion, which will set immediately. Run a sharp-pointed instrument round the film to the depth of an inch, and place the plate in a tray containing a solution of acetic acid in water 1 : 5. When the film is loosened, the stripping and reversing is done in the usual manner. By the way, would not such a strong solution of acetic acid have some considerable solvent effect on the gelatine?

In an article in the *Photographic Times* Mr. W. Jerome Harrison says that the first notice he has been able to find of the commonly adopted process of intensifying by bleaching with mercury followed by ammonia is contained in Hunt's *Manual of Photography* of 1853. On referring to Scott Archer's *Manual of the Collodion Process*, published in March 1852, we find detailed directions given for whitening the image by mercury, after which he adds: "After this bleaching it can be changed into a deep-toned negative many shades darker than it was originally, by immersing it, after a thorough washing, in a weak solution of hyposulphite of soda, or a *weak solution of ammonia*. The white picture will vanish, and a black negative will be the result." This establishes the priority of Archer over Hunt.

Some months ago we wrote in favourable terms of some bromide prints with most charming sepia tones by Messrs. Inglis & Co., of Chicago. Mr. Inglis was recently present at a meeting of a New York photographic society, where the subject of uranium-toned bromide prints was under discussion, and said his company's process differed in every feature from the uranium toning method. The basis of the tone, in fact, on their papers was within the preparation of the paper, and a patent had been applied for. We suppose that what is meant is that the toning basis is in the emulsion with which the paper is coated. Such a process of toning, as we pointed out in a leading article a short time since, would be very welcome. The tones of Mr. Inglis's prints are equal to any of those produced by the uranium bath, which is high praise.

The movement for organizing a Photographic Assistants' Union in this country unfortunately never came to a head, although there was a universal agreement that such a Union was not only practicable, but desirable. In New York the assistants are forming a Union for the purpose of securing redress for the numerous grievances of which they complain. These are headed by "miserable wages." More than this, they assert that they are scorched on the roofs in summer while looking after the printing, and frozen in the winter. All the blame for bad work is shifted on their shoulders by the employers. They also allege that they have to compete with a lot of young men who are not adapted for the business, and, by accepting low wages, keep down the standard of wages all round. We wish the Union every success. Some of the New York grievances are not unknown in this country, and the pity of it is that they are at present practically irremediable.

The establishment of another monthly Canadian photographic journal is announced. There is already one largely devoted to the interests of photographers in the Dominion, the *St. Louis and Canadian Photographer*, the publisher and proprietress of which (Mrs. Fitzgibbon-Clark) must be congratulated upon the energetic manner in which her journal is conducted. *Apropos* of the Maddox Testimonial, now being raised both in this country and America, the *St. Louis and Canadian* makes a strong and generous appeal on behalf of one of its own countrymen, Professor H. H. Snelling, who is one of the fathers of photography in America, but who is now aged, blind, infirm, and in destitute circumstances. Let us hope that such a response will at once be made as will place him, not only beyond want, but in comfortable circumstances. It is not to the credit of America that one like Professor Snelling should be allowed to remain in want of the necessaries of life.

LANTERN SLIDES BY THE CARBON PROCESS.

The carbon process for lantern slides possesses several advantages over those of any other. For example, it is easy in practice, the pictures can be produced in any colour, and certain parts can be dodged by local treatment in the development; also, the tones of the slide can be modified after it is finished. For these and other reasons the process is one that should especially commend itself to the amateur and others desirous of obtaining variety in effects.

The practice of the carbon process has been much simplified since the Autotype Company and other manufacturers have supplied the paper in small quantities sensitised and ready for use. Not only is the trouble of sensitising avoided, but the tissue is secured in the best condition for work. It is now tolerably well known to most of our readers that, in carbon printing, one of the most important points is that of sensitising and drying the tissue, and when this is accomplished satisfactorily the whole of the after-operations are simplicity itself. Most amateurs who go in for carbon lantern slides will, we surmise, prefer to purchase the tissue ready for printing; however, this article would not be complete without instructions for sensitising it at home.

With regard to the choice of the tissue for lantern slides, this is quite a matter of taste. There are several shades of brown and purple in the market, as well as red, sepia, and other colours, all of which are suitable for lantern slides. A special tissue is made for transparencies, the colouring matter of which, we believe, is China ink, which yields an excellent black picture. In this tissue the pigment is said to be in a fine state of division, and in greater quantity than in any of the others. Still, as we have said, any ordinary tissue may be used with good result; indeed, in some cases, as will be explained further on, a tissue highly charged with pigment is not desirable.

There are different methods of procedure in sensitising carbon tissue. Some simply immerse it in the bath, take it out, and then hang it up to dry. Some, after taking it from the solution, place it on a glass plate and pass a squeegee over the back before suspending it to dry. Others, after the tissue is removed from the solution, squeegee it upon a collodionised glass, and allow it to dry *in situ*, and remove it afterwards. When either of the latter plans are adopted, the bath should be used a little stronger than in the case of the first, inasmuch as there is no superfluous solution left on the surface to afterwards soak into the tissue.

For lantern-slide making, a suitable sensitising bath, for this season of the year, is one of three ounces of bichromate of potash dissolved in three pints of water, to which is added a drachm of strong liquor ammoniæ. The bath should be made up a day or so before use, then the upper portion can be decanted from any sediment, and thus dispense with filtration. It may be used many times, but should be discarded as soon as it acquires a decided brown colour. The solution is poured into a dish to the depth of half an inch at least. In this, after being carefully dusted, the tissue is immersed, all air-bubbles, of course, being removed until it becomes quite flaccid, which it will do in from two to three minutes, according to the temperature of the solution. It is then taken out and placed, face downwards, on a glass plate, and a squeegee passed lightly over the back to remove the superfluous liquid, and then hung up to dry spontaneously in a room free from the fumes of burning gas or other noxious vapours. For suspending the tissue, there is nothing better than letter-clips. Those known as the "Bulldog Clips" are the best for the purpose, as the jaws of them cover a space of two and half or three inches, and thus secure a firm hold on the wet paper. The drying should be effected in from six to nine hours, otherwise there will be a danger of the tissue becoming insoluble. It should not be allowed to become over-dry, that is, crisp, or its sensitiveness will be impaired, also there will be a difficulty in obtaining perfect contact with the negative in the printing frame.

The above method answers very well for ordinary work, but for lantern slides the following one should be employed. Take some glass plates, say, twelve inches square, as that size will suit sheets of tissue, from which nine lantern-size pieces can be cut. Prepare the surface by rubbing it over with French chalk, and then coat it with plain collodion. Commercial enamel collodion will answer. After the collodion has well set, place the plates in water until all greasiness is removed; or the ether and alcohol may be washed out under the tap. The glasses are then well drained, and the tissue, after it is taken from the bichromate solution, is squeegeed, face downward, on to the collodionised surface, a piece of indiarubber cloth being used to prevent injury to the film, and allowed to dry on the glass. This system of sensitising and drying possesses several advantages for lantern-slide making. The surface of the tissue is protected from dust. It is not exposed to the atmosphere while drying, which, if it contains any injurious vapour, would tend to cause a degradation of the light when the picture is developed. The surface, when stripped from the glass, is perfectly even, so that the best contact with the negative is secured. Further, an otherwise after-operation is saved. The tissue may be sensitised in the light of an ordinary room, as, while it is wet, it is practically insensitive.

When the tissue is dry, it must be preserved from the air, either by keeping it in a metal case, or under pressure between glass plates. If it be dried on the collodionised glass, it is best preserved by keeping it on the plate, and only stripping it off when required for use, the plates being packed together, tissue to tissue. When tissue is dried under the conditions named, it will keep in good working order for from one to three or four weeks, according to the time occupied in the drying and the care with which it is kept.

The pictures may be developed on plain glass, or on a substratum of collodion. But, as gelatine is a highly contractile substance when subjected to heat, it is advisable, in the case of lantern slides, to have a very tenacious substratum, such as one of insoluble gelatine. This forms a good one: Nelson's "No. 1" photographic gelatine, an ounce dissolved in a pint of water. To this sufficient bichromate of potash is added to just give a pale lemon colour. The plates, after being thoroughly cleaned, are coated with the solution and allowed to dry in a good light. The light renders the coating insoluble. Theoretically, plates so treated should have a slightly yellow tint, but practically they have not when finished. However, here is another formula that will yield a substratum free from any suspicion of colour: Gelatine, as before, one ounce; water a pint; when dissolved, add twenty grains of chrome alum in one ounce of warm water. Plates prepared according to either formula will keep for many months if kept dry. Therefore a good stock may be made at a time.

We have treated the sensitising of the tissue in detail, although we assume that the majority of amateurs would prefer to purchase it ready sensitised, and thus avoid the trouble of doing it themselves. We shall now proceed to the printing. In the first first place it is necessary to protect the edges of the tissue from the action of light while it is being exposed; otherwise, when the picture is developed, it will frill at the margins. The most convenient way of providing a "safe edge" as it is termed, in the case of lantern pictures, is to place on the negative a lantern-slide mask, with an opening the same size as, or preferably a little larger than, the finished picture is required.

The tissue, cut a trifle smaller than the glass plates, is placed on the masked negative and exposed to light, the same as in silver printing; but, as the image will not be visible when printed, the exposure should be judged by an actinometer, of which there are several forms in the market. Or a negative may be selected of the same density as those to be printed from, and that, with a piece of albumen paper upon it, used as a guide for exposure. With regard to this, it may be mentioned that it is governed very much by the quality of the light at the time of printing.

Carbon tissue of normal sensitiveness, if printed in a strong light, requires but about half the time of silver paper; whereas, if it be printed in a feeble light, quite as long an exposure will be necessary. For transparencies a much longer exposure is necessary than what would be required for carbon pictures on paper—double, at least. As considerable latitude is allowable, it is better to err on the side of over rather than under-exposure, as there is great scope for remedying it in the development. As will be explained presently, what might be termed over-exposure is a positive advantage in some instances. It may be explained that carbon tissue becomes more sensitive by keeping; therefore, that which has been kept for a week or two will require less exposure than that just sensitised—in some cases not more than half. If the tissue has to be kept many hours between exposure and development, allowance must be made in the exposure. It is now pretty generally understood by the majority of our readers that

the action of light on carbon tissue, once started, goes on in the dark; consequently, if the image is not to be developed as soon as printed, the exposure must be curtailed according to the state of the atmosphere. Heat and damp accelerate the action, while cold and dryness act as a retarder.

The tissue being exposed, we now proceed to the development of the image. For this a deep zinc or tin tray is usually employed; but, of course, any other vessel will answer quite as well. If the tissue in sensitising was not squeegeed on collodionised glass, it should now be coated with collodion. This is easily done by pinning it by three of its corners to a small piece of thin board—such as a piece of cigar box—and then pouring the collodion on and off at the free corner, as in coating a glass plate. The collodionising may be dispensed with; but, as it possesses several advantages, and involves so little trouble, it should always be adopted, particularly when it is desired to modify the tone of the picture after it is finished. The collodion being dry, the next operation is to mount the tissue on the glass.

The plates, prepared as described in the former article, are placed in a dish of clean cold water. A piece of the exposed tissue is then immersed until it becomes slightly limp, but not so limp as is usual when working on paper. It is then placed, while still in the water, on one of the plates, so as to avoid air bubbles, removed, laid on a flat surface, and then well squeegeed down. A sheet of macintosh cloth may be used to protect the back of the paper, but, with plates prepared as directed, it is scarcely necessary. If, however, the glass be coated with collodion instead of insoluble gelatine, as is sometimes done, then the macintosh is essential to protect that film from injury. The prints, as they are mounted on the plates, are piled one upon another, with a piece or two of blotting-paper between each, with a weight upon the top one. The whole is then allowed to remain for ten minutes or so, and they are then ready for developing.

To develop, the plates are placed, tissue upwards, in a dish or tray of warm water, temperature 90° to 100° Fahr. In a few minutes the colour will begin to exude from the edges of the paper, which should then be stripped away, and the development allowed to proceed. This will be assisted by laying the water over the surface with the hand. The development is complete when the whole of the pigmented gelatine unacted upon by light is washed away, and the highest lights show without veil, when the picture is laid on white paper. This, if the picture was lightly printed, and the tissue freshly sensitised, will occupy but a few minutes; but, if it has been darkly printed, as it should be, it will take ten or fifteen minutes, or even longer. When this is the case, it will be found more convenient, when the major portion of the gelatine has dissolved, to transfer the pictures to clean water at a higher temperature, say, from 100° to 110° Fahr., as they can then be the better seen.

At one time grooved developing tanks, such as those used for the development of Woodbury reliefs, were sold. But it is obvious to any one that, if the plates are placed in an ordinary washing and draining rack, and that is suspended in a vessel of warm water, say, a large tin saucepan, over a small gas-jet, it will answer every requirement when a prolonged development is necessary. Indeed, for lantern slides such an extemporary arrangement will be found more convenient than a tank with fixed grooves. Should the pictures prove very much over-printed, they need rarely be lost, as it is simply a question of time and temperature in the development. In such cases, the heat of the water may be increased to 120° to 130°, and the time prolonged until they are sufficiently reduced.

It may be well to point out here why the advisability of deep printing has been so strongly emphasised. A darkly printed transparency, forced in the development, is always more brilliant than one that is lightly printed and quickly developed. Again, if the tissue has been kept for a long time, or it was dried under adverse conditions, the picture will often prove fogged or veiled in the lights when developed. This veil, however, will be dissolved away with a prolonged development, though it would not with a brief one. Furthermore, deeply printed slides, reduced in developing, do not require treatment with alum, which, by the way, is no improvement to the picture. If, however, the slides are lightly printed in the first instance, they must be immersed for a few minutes in a five-per-cent. alum solution, and then well washed to remove the excess of alum from the film. The reason for this is that, with weak printing, the gelatine in the lighter portions of the picture is still soluble, if sufficient heat be applied in the presence of moisture. This latter, as many are aware, sometimes finds its way between the two glasses; hence the heat of the lantern, but for the aluming, might cause the film to run. When the development of the image is completed, the plate is well rinsed under the tap, and the transparency put away, to dry, where it will be free from dust.

It may be pointed out, for the benefit of novices, that, from the time the printed tissue is placed in the cold water, prior to mounting it on the glass, all the operations may be conducted in broad daylight.

A QUIET NOOK ON THE NORFOLK COAST.

It is presumed that photographers, both amateurs and professionals, are human flesh and bones as other folk, and as the summer comes, with its regular march, accompanied often by irregular weather, they both think with a sigh it is time to rest their weary minds and wish for a change for themselves and their little group. Then comes where to go.

In advising a holiday haunt there exists some difficulty in the different opinions and tastes how to spend a holiday. The quiet man would shun a destination thoroughly suitable to a party of merry single young chappies on fun and frolic bent; still, as it's impossible for one drug to cure all and every complaint, it only remains for yourself, as the ever-wise dispenser, to select and mix in quantities and proportions such as you deem most suitable for general purposes. I, as a young man, with wife and juvenile family of three souls, have found always everything to meet our requirements on the Norfolk coast. We frequent a little place known as Maundsley, situated between Cromer and Yarmouth. Although we don't stay at Maundsley Proper, there can be found nice, clean little cottages at very reasonable figures for a little family there. It is a fishing village; it is quiet and very quaint; so quiet, indeed, that hardly ever more than a dozen people are to be seen on the beach at one time, and no stalls, niggers and hawkers, more or less frequent with other seaside resorts, are to be found. Now, to a man not receiving the salary of a prime minister or prize-fighter, the question of railway fares will, do what you may, present itself strongly, more or less, according to the distance. In this respect the Great Eastern are indeed generous to the public, and also not too particular as to whether a child *is* or *is not* three years by a few seconds; or the eldest *has* or *has not* just struck twelve. I have seen young people go on long rides with a half-ticket that anywhere but on a rail car would no doubt feel highly offended did you consider them so young in years; still, as before mentioned, in the particulars of ages they are not severe, and no doubt are in the long run gainers by not so being, as, did they roam among their passengers with the eagle eye, many and many families that now get once a year the bracing sea air would by compulsion stay near at home, and the company lose such traffic as they now get; therefore the public admit of their generous spirit, and give them all the business they can. This is a digression; still, to many, this information may be especially interesting.

The two nearest stations are North Walsham or Gunton, from the first there runs a bus landing you right to the destination. The return fares are 15*s*. for a fortnight, 10*s*. Friday till Tuesday. The distance is 134 miles, and there are fast trains.

We locate ourselves with friends at a farmhouse hard by, and our days are generally passed by early rising, the little ones liking to fetch from the henhouse eggs for breakfast. Then comes the packing basket with eatables for dinner or lunch, then all is ready for our conveyance. It must at once be known, in Norfolk the much-abused donkey—or "Dickey," as they call him—is in great request, and, with a nice, smart village cart tagged to him, there is something much worse to be had, although many may think differently; still, such is my experience. We then add a large-size umbrella tent, and away we go.

Reaching our destination within two miles, the little vehicle is put up at the "Life-boat," and a short incline leads on the beach—a beach of the softest sands, and miles in distance both to the right and left. We pitch our tent, get the youngsters ready for wading, and the fun commences. We can use the tent for many purposes. The tide may be ready, and I visit the Coastguards, and borrow, for a few coppers, a full-size shrimping net, a rough, old, tattered-and-torn suit, consisting only of an old blue pair of trousers cut to the shortness of knickerbockers. Back to the tent, soon reappearing *à la* Robinson Crusoe, and so beautifully disguised that your nearest friend all but fails to recognise you in your altered condition. With your net-pole across your shoulder, you push out to the desired depth, net in front, every little while coming back to a dry sand-bank, and throw out your catch of small fry and hopping shrimps, to the immense delight of the little ones waiting to snatch them up, half timid, and drop into the large basket brought to take home the day's sport; and so you push on until the return of the tide closes your labour. Two of us have frequently taken home a bushel of splendid shrimps, had them cooked, and served hot for tea. On a beach of this kind there are no restrictions, and no dangerous breakwaters to the danger of the children. Ladies can as easily bathe as the men. Many erect a tent, and leave it standing the term through.

After some hours of this we all return to a jolly Norfolk meat tea, where everything the house possesses is placed on the table. The children are sent to bed, near friends call in, and the evening soon passes in music, and song and mirth ending a fairly representative day of many.

From North Walsham and Gunton you can easily reach by cheap excursion train many well-known places, as Cromer or Yarmouth, while I find many wonderful pleasant days in company with rod and line. A 1*s.* 6*d.* ticket gives you a return fare to Wroxham Broads, a most beautiful stretch of water, from which can be taken a good load of fish. All these rivers and broads are wild and wonderful. Again, the lanes in Norfolk are very pretty indeed, abounding as they do with an ever variety and multitude of wild flowers and strawberries, while the ferns are in profusion for species and quantity. A road trip to Gunton Park is one worth doing, and one to recollect. About here is simply alive with game of all kinds.

Norfolk people are homely and kind. They are clean and reasonable in their charges. I have had a good bed and eggs and ham breakfast before now, the whole costing less than 2*s.* Going back to Maundsley, you can find superior classes of houses if you desire, and you have a telegraph office, post office, provision merchant, boot dealer, in fact dealer in general, all done in one little shop, with a low door that you must bob to get in. To those who wish quietude and no restraint, by all means give this haunt a trial. The Great Eastern Railway issues free a little pamphlet entitled *Farmhouses and Lodgings*, which every one should possess before deciding.

T. Coan.

OUTDOOR PHOTOGRAPHY.

I.—Introductory.

The principal object of this short series of articles is to endeavour to afford some assistance to young members of our craft whose fate or inclination it is to have to earn a living as an outdoor operator. As the writer is fully aware of the disappointments and difficulties in the way of success, he will try, in as practical a manner as possible, to communicate his experience. It will possibly be old news to old hands who are well acquainted with the abundant literature of the subject which has been published in the past, but which, nevertheless, is only accessible to very few who have entered the ranks at a later period. The desire to provide for the latter class must be the excuse for reiterating what, perhaps, has been written again and again.

The practice of outdoor photography as one of these, is a very different thing to skimming the country with a hand camera for pleasure, under no compulsion to put forth effort to produce anything good, or to go beyond mere plate spoiling, the thing most to be wondered at in such proceedings being that so many can be found to take so much trouble to prepare plates for the sink when it can be done with much greater ease at home by simply opening a parcel of them in daylight. One fair result per hundred of plates used would scarcely satisfy a first-class employer, even if it proved a model picture; sixty to seventy per cent. for all-round work is more like what is expected, and these obtained under all conditions of weather and mood of the man. Many of the writers and speakers who profess to know so much of the matter are entirely ignorant of the routine of photography as a business, and I venture to say that if they were placed for twelve months in a good house their general estimate and ideas of the possibilities of photography would undergo a great change. It would be a thorough clipping of wings. To take orders over-night, or perhaps with only an hour or two's notice, for all kinds of photography—including landscape, group, cattle, outdoor portraits, shipping, &c.—and do the work at the time appointed, is something different to contemplating a scene for a twelvemonth and taking it a few dozen times before anything worth printing is obtained, and that possibly coming decent through no fault of the man. Understand, the writer has no wish to decry the spirit of thorough painstaking and desire to put character into one's work. It is worthy of all praise, and, provided extra carefulness does not interfere too much with the number of negatives produced in the day's work, will be appreciated by employers and paid for accordingly. To be uniformly successful in photography, a thorough training under such influences is necessary. Skill and resource and cultivated judgment only come from long practical experience, and are neither bought with a dozen quarters or a guinea set. Fortunate is the aspirant who has had the privilege of receiving a few years' preliminary training under such circumstances; then he may feel some confidence that, when the time comes for him to take sole charge of the outdoor branch, he will not be at fault in dealing with work not unusual in character. If, in addition to this, he be a lover of good order, and take a delight in keeping things nice, he will be an acquisition to any establishment, and his value soon become known.

When entering upon a fresh engagement, it is a good plan to have an understanding as to the apparatus set apart for outdoor work, to note well its kind, and carefully examine it as to its fitness for the purpose; to have any small repairs attended to, and make suggestions as to what is desirable to add to the "kit." Some ask permission to take charge of it, and find some nook where it may be placed and kept in readiness for immediate use. An endeavour must then be made to impress upon others in the firm the necessity of asking permission to use any article, and of returning the same to its place in good condition as soon after it is done with as possible. Should there be a slovenly man about, the wisdom of this course will soon appear. The necessaries for various kinds of work should be tabulated, and lists of contents or belongings pasted into cases or other receptacles used for packing the traps. A system of this kind abolishes half the "wear and tear" of getting away to a job, and leaves the operator free to think over the details of the most important part of his duties—that of making the photographs. Let no pains be spared, go completely equipped, intent upon doing the best that can be done, with means for developing a plate, or the whole of the work, on the spot if it be of an uncommon or uncertain kind. With this extra trouble the business is light compared with what was absolutely necessary when wet collodion was in vogue. The preparation and paraphernalia necessary for successfully working this process would astonish modern men. Six months' practice of it by each would-be photographer would go far towards extinguishing the craze for the saving of trouble, and the sacrificing of the most desirable qualities in apparatus that the outfit may be a few ounces lighter, and have the effect of thinning the ranks to the advantage of men of more solid cast who are unaffected by considerations of this nature.

After the work is done the list must be run through to see that everything is present before quitting the ground, and on arriving at home, especially if the weather has been damp, the camera and slides should be opened out and placed neatly together till there is leisure to look them over and place them ready for another jaunt. Any peculiarity worthy of note or to be guarded against in using any part ought to be jotted down, and some definite mark made in the list against it; then, whatever time elapse before it is required again, the preliminary scanning of the list will warn the operator and prevent his being taken in a second time. Strict attention to such small matters saves much vexation and disappointment, as it often happens that an otherwise good negative is spoiled by some trifling defect from a cause that the slightest inspection or a moment's thought would have detected.

For the benefit of those who have the privilege of being able to order what they require, instead of taking to and making the best of things as they find them, the writer will endeavour in another article to show how to make a selection and distinguish between mere fads of construction and really useful contrivances likely to stand our splendid climate. Every old hand knows quite well that a piece of apparatus is one thing in the warm and dry atmosphere of a dealer's show-room, and quite another after use outside.

John Harmer.

REVERSAL.

[A Paper read before the Camera Club, and printed in its Journal.]

In opening the subject of reversal this evening, it would be well to understand that a reversal negative and a reversed negative are different things, a reversal negative being the result of what has been termed reversing action; it is produced direct from a negative, and is reversed as regards right and left. A reversed negative is reversed as regards right and left, but is produced from a positive.

We all know that over-exposure produces flatness owing to the difficulty of obtaining density in the high lights; it is easy to conceive an exposure sufficiently prolonged as to cause an entire loss of the high lights. If in such an exposure the shadows have not received sufficient light to produce a strongly developable image, the result on fixing would be an extreme case of over-exposure, as understood by a thin image; but, if during development stray light obtains access to the plate, the shadows fog, and we have reversal.

The original high lights, as we shall see this evening, are both undevelopable and insensitive, therefore do not fog. We may produce this fog by preliminary, concurrent, or supplementary exposure; in all my experiments it is deliberately produced in order to supply the necessary reduction to those parts of the plate not rendered undevelopable by oxidation.

In a reversal exposure this oxidation is regulated by the interposed negative or positive; therefore, when we fog or expose the still sensitive portions of the plate, a reduced image is formed capable of being developed.

In our experiments this evening the reduction will be produced by concurrent exposure, that is, while we are oxidising through the shadows of the interposed negative, we are fogging or reducing through the high lights with stray light.

In order to illustrate this matter, I will expose a plate to magnesium light a sufficient time to enable oxidation to produce the undevelopable and insensitive state; another plate will be taken, and the pair exposed in contact with a negative. I think we shall find one plate give a reversal and the other show it is really undevelopable and insensitive. The insensitive or oxidised plate will show the state of the shadows in the reversal plate, this latter having a gradation of oxidation and the rest of the plate fogged. The insensitiveness may be only comparative, for, though the plate has still the power of producing a print-out image, I have not succeeded in producing a second developed reversal from it. Captain Abney has shown the undevelopable state is due to oxidation.

Although it is possible to produce an exact reversal, I do not think these physical reversals are of much practical account, from the fact that a very exact balance in the two factors of reduction and oxidation is necessary. If the latter be in the least overdone, the delicate tones are oxidised out of existence; or, if the reduction has been too much, delicate tones are fogged and disappear. Under these conditions the gradations are quite false. In some cases reversal improves the result; subjects having too many tones may have the middle tones obliterated. Hard negatives are reproduced perfectly.

I have here a reversal negative, the print from which represents the sixth photographic image. The cloud and cattle negatives were separately taken, and a combination glass positive made from the two; from the positive a contact negative was made, and from this a reversal negative, then from the latter the print.

One of the small prints represents the fifth image, the series being original negative, glass positive, contact negative, reversal negative, and platinum print.

The villa print also represents the fifth image, the series being original negative, silver print, camera negative, reversal negative, platinum print. The river print series runs: original negative, reversal negative, platinum print.

In producing the four prints, nineteen photographic images have exerted their influence, rather a severe ordeal for the original images to pass through. It is unnecessary to say there is some loss. While these are being passed round, I propose making a reversal negative from an ordinary negative.

When making experiments of this kind, the natural conclusion one arrives at is, that dark flashes seen on photographs of lightning are the result of reversal.

In Australia we have some of the finest electric storms, and there I have seen many flashes, the impression of which on the eye was of greater duration than would be due to persistence of vision.

On one occasion I was fortunate in observing a brilliant thread suspended between two clouds for several seconds. I mention this to show there are discharges of exceptional duration.

The light from one grain of burning magnesium is sufficient to produce reversal, as we shall see by experiment this evening. So we may consider a lightning flash having a similar actinic or photographic value should do the same. This value may be due to a discharge of exceptional duration, or to a brilliant flash caused by a maximum electromotive force with a minimum quantity of matter in the path of the flash.

One evening I was observing a display of electric discharges in a large cloud situated on the northern horizon; these discharges were accompanied by sympathetic discharges in a cloud on the southern horizon. The northern cloud was approaching, and I concluded that, should the clouds be at different altitudes, a difference of air currents might enable the one to overtake the other.

A more rapid movement of the northern cloud was soon noticed; a camera, fixed up and carefully focussed on the southern cloud, by aid of the local discharges. All being in readiness, and the shutter of slide drawn, but cap still on the lens, I waited events. When the northern cloud reached the zenith, it began to show considerable symptoms of electric excitement at the edges. Knowing this to be my opportunity, the lens was uncapped, and in about half a minute a pair of brilliant flashes darted from the zenith to the southern cloud. I estimated the duration at over one second.

The plate was immediately developed, but not a sign of the flashes. I expected to find a pair of curly black streaks right across the plate; instead, there appeared a very fair cloud negative, and the black outlines of some buildings low down in the field. These buildings enabled me to verify the position of the camera, which, being attended to, proved the field must have included the flashes. I could never account for getting the clouds and not the flashes, until the matter came to mind whilst making the reversal experiments, and now think the exposure reached the transition stage described in experiment 14 of my paper in the *Club Journal* for September. I give these particulars to show every care was taken in the endeavour to photograph the pair of flashes. * * *

There may be points which, with our present limited knowledge of the dark flash, seem difficult to reconcile, still I think we are pretty safe in accepting reversal as the cause.

One of these points is stated by Professor Burton in *Photography*, September 17, namely, the crossing of dark and bright flashes being bright. This is probably due to an electrolytic creeping action of the deposit across the dark flash during development, and not due to the reducing action of light. If the dark flash be due to the undevelopable state produced by oxidation, then at the point of crossing the difference in condition at the junction between the reduced and oxidised flashes is probably sufficient to produce a difference of potential, that may determine an electrolytic action. A plate brought to the insensitive state by oxidation should form a very fair couple with a plate simply reduced; it is difficult to conceive it otherwise, for where there is reduction or oxidation we invariably find electric energy, and when we find electric energy under suitable electrolytic conditions there we find reduction and oxidation.

HENRY SUTTON.

PREPARING STRONG FERROUS OXALATE.

[A Communication to the Photographic Society of Philadelphia.]

THE strongest form of oxalate developer, made by dissolving ferrous oxalate in potassium oxalate, is not as much used as it deserves to be, the explanation of which, no doubt, is to be found in the very considerable amount of trouble entailed in the ordinary manner of preparing it. Thus, two distinct procedures are required; first, the precipitation of the ferrous oxalate; then the solution of it in the alkaline oxalate, which operation is not very satisfactory on account of the tendency to oxalation if heat be applied for any length of time. In trying to find a more convenient plan of getting a saturated developer I hit upon the following, which I find answers every purpose.

By estimating the quantity of iron actually in solution in different developers, and further by the point (volumetically), when precipitation takes place I found that I could not in any way make a developer which should permanently contain over about 0·65 grains of ferrous oxalate per 10·0 c.c. Acting on this datum I took a saturated solution of potassium oxalate, and to it added an excess of the oxalate, which would be sufficient to convert enough ferrous sulphate to make the 0·65 gramme of ferrous oxalate. The excess of the alkaline oxalate so added was gotten into solution by heat, when the iron was added. In this manner a developer was produced without excess of anything, except the inert potassium sulphate formed in the reaction.

In comparing a developer so obtained with the strongest form of the ordinary one (say, that issued by the Eastman Company for their bromides), we find that the latter contains for every 10·0 c.c. 0·59 gramme ferrous sulphate, which quantity can only give 0·3 gramme of ferrous oxalate, as against at least twice that in a saturated developer.

In practice, the most convenient way to make up is to dissolve the full quantity of alkaline oxalate at once in water, so that the formula reads:—

Potassium oxalate	330·0 grammes.
Ferrous sulphate	135·0 „
Water	600·0 c.c.

Dissolve the oxalate by acid and heat, then cool until it just begins to be precipitated, then add the crystals of iron at once. After solution has taken place, cool completely as rapidly as possible (I place the containing vessel in cold water), and filter off into closed bottles.

In the above we have 250·0 grammes of potassium oxalate which remain in solution, while the other 80·0 grammes are lost in forming the oxalate.

The quantity of water necessary to hold 250·0 grammes of potassium oxalates in solution is 760·0 c.c., but we need only take 600·0 c.c., since the 135·0 grammes of ferrous sulphate will furnish 60·0 c.c., the sulphate crystallising with seven molecules of water.

The oxalate of iron is slowly precipitated after the bottles have stood some time, therefore it is better not to make up a large stock at a time. The formula is calculated to give an excess of ferrous oxalate of 0·15 grammes in each 10·0 c.c., most of which will remain for a short time in solution. The iron and potassium oxalate are balanced.

C. W. MILLER.

COMPOSITION AND SELECTION OF SUBJECT.

[Read before the Holborn Camera Club.]

IN introducing this subject to you this evening I feel that the more I consider it the more difficult it appears to be. It is far removed from the technical subjects which we so frequently have demonstrated so ably to us in this room. I wish it were in my power this evening to be able to practically demonstrate in the field of nature; for, with the camera on its tripod and nature before us, I could soon show you the force of some of the principles which I wish to advocate this subject. The subject of my lecture as issued in the monthly notices is "Composition," but I find it next to impossible to keep it distinct from its sister subject, "Selection of Subject," and it is with your forbearance

that we will consider the two subjects this evening. I find the difficulty in separating the two subjects is, that we must first educate the eye to see in nature what will form a picture, and when this is done to apply the leading principles of composition to it. This cannot be done without study; and, as a rule, when this is disregarded we find that the worker frequently wonders why he cannot get the same result as other workers, who frequently are not perhaps such good photographers from a technical point of view. This is, to some extent, due to artistic training, and the photographer who has these instincts will in most cases excel. I am not advocating that an artist is a born genius, for, in my opinion, his success is only the result of hard study met with frequent failures. But even the failures instruct him, insomuch as they teach him what to avoid. What to avoid; that is the point. If amateurs were to give this a little more thought, their collections of photographs would be very different to what they are at present. We must remember that it is quality and not quantity that should be our aim. Our aim should be to produce work with which we do not tire, and I maintain that a good photograph may do so. It must always appear pleasant to the eye. Not on account of its beautiful shining finish, or its delightful matt surface, but because it portrays to the eye an impression of nature which is beautiful. I would most earnestly urge you to study the selection of subject, and one way in which this may be done is by not missing an opportunity of looking at examples of pictorial art, and at every example look beneath the surface and try to realise what makes it look so pleasant and what mars it. By doing this I am sure you will be able to apply it with ease when out on photography bent.

With regard to composition, I am sure the need to study this important item in regard to photography must be obvious to every member of this Club, for, although it may be quite possible for us to produce fair work accidentally without such knowledge, it is not this that we must seek. I am sure that the earnest endeavours of one and all is to be able to make the most of any particular subject as we see it before us in nature, and I will before you a few well-known rules and try to apply them to photography. We must remember that we have not the free lance of the artist who can omit any objectionable feature that is before him, and, knowing this, it should make us much more careful in our selection of a suitable subject. We must also remember that we are not working in colour but in monochrome, and I venture to say that there is not one of us present who has not noticed the difference between what we imagine we have treasured in our dark slide, and what it eventually turns out to be.

We sometimes wonder, perhaps, at a club outing what Mr. A—— can be doing, and when we ask him how many plates he has exposed he replies, "Not any at present." You have seen him wandering about most probably by himself, focussing several objects, on which many plates have been exposed. What can he be up to? Why is he not satisfied with this or that? You are sure they will come out well. These matters pass through our minds. Well, I will tell you what he is up to. He is looking for a picture and not a mere photograph. He is, perhaps, waiting for a certain light, and later on he will take advantage of that light. I venture to say "that a thing worth doing is worth doing well." It is working at random and taking anything and everything that I am to-night trying to condemn. I think you will agree with me when I say that we are far too anxious to expose our plates, and I think it would be a very good plan, which I believe was suggested by Mr. H. P. Robinson, to ask ourselves the question, "Will it do?" I think that if this question were asked, there would be less exposures and a corresponding gain in the quality of work. The number of negatives which are never printed from is enormous, and the reason why it is so is, because all interest in the subject has ceased on the conclusion of development. Now, "a thing of beauty is a joy for ever," and there are some photographs which never tire one, no matter how long you have had it. Our chief aim should be to produce this sort of work.

You will, I am sure, pardon such a long introduction to the subject really before us this evening. I have nothing very original to tell you. Art is not new, but it has laws which must be obeyed. The eye must be trained to see the making of a picture; and, again, let me impress upon you to look thoroughly at the work of eminent artists, and try to find the reason why the picture is so beautiful. If this advice is followed, I am sure you will be able to apply it to your work with the camera.

I will now briefly mention a few leading features which may assist you:—1. Avoid having the principal objects in the centre of the picture. 2. The horizon should never be in the centre of the picture, but rather below or above it. 3. Avoid straight lines. Take the subject, if possible, at an angle, and you will get a much better perspective of it. It will also tend to break the flatness of the picture. 4. Avoid repetition of lines. 5. Avoid an uninteresting and unbroken foreground. This can often be overcome by the introduction of figures, which, however, must be in their proper place.

In introducing figures be careful that they are in harmony with the surroundings, and be careful also not to include a friend also busy with his camera. Avoid, also, the attention of the figures being directed towards the camera. This is an objectionable feature which spoils so many otherwise good photographs. Take them in as natural a pose as you can, and then your picture will tell its own tale. Assistance in these rules may be gained by ruling the focussing screen into three equal divisions each way, making nine divisions on the screen, and where the lines intersect is termed "the forte points." These are the best positions for prominent features in your picture. They are also generally the best position for the introduction of figures in a landscape.

Now, I must ask you to give an eye to the future of things, and I must ask also you not to think that the following remark is intended in the slightest degree personal. I ask you, Is the outside of a village inn the place for taking club groups, or our friends, the cyclists? This same spot may be an excellent accessory to the villagers, with their waggons and implements of agriculture, but I must certainly raise a protest to any of us handing down to a future age the insinuation that we, when out on our hobby, were all as bad as the proverbial cobbler or tailor keeping St. Monday. A little more thought and seriousness in our work is all that is needed, and let not one of us willingly bring our art science into ridicule. We are here individually to benefit one another, and the knowledge we have I am sure is at the disposal of each member, whether upon the field or upon technicalities. In advancing this we are helping each other in the path we traverse together. Let the path be one of progress. Let each try as they go on to produce better results, and be not discouraged by failures. Let the latter teach us the real road to success.

A. J. Goldino.

NOTES FROM SCOTLAND.

(By Our Special Correspondent.)

As one of the evidences of the generally good state of professiona business, a new departure may be noticed in the "Leaderdale Photographic Art Works," which have been built and opened by Messrs. M. and T. Scott, and are intended to be strictly devoted to artistic work for the profession, they, so far as the public is concerned, entirely sinking their own personality. The present design embraces enlarging, retouching, tinting, painting, copying, &c. The works are situate in one of the finest positions possible, on the outskirts of a city which is of itself almost a romance, at the base of Blackford-hill, of the view from which Sir Walter Scott makes Blount say, after he has fully described its beauties, and been animated by the prospect—

> "Where is the coward who would not dare
> To fight for such a land?"

Having paid a visit there recently, a description of their appliances and methods of work may prove practically valuable, especially to those desirous of going in for a big thing, and establishing other proofs that professional photography is not yet played out.

The place is of easy access by road, tramways, and rail from every part, and in going so far afield care has been taken that there can be no building up; the district having been secured by the city as a public park in perpetuity, thanks to the authorities; but none to those who, in the midst of this sylvan beauty, chose to erect an iron and stone ornamental gate, as a monument to Sir George Harrison, who, as Lord Provost and M.P., secured this unique park for the city. Think, citizens! inhabitants of London! of an ornamental gate to Epping Forest or to Hampstead Heath! That is the one detraction to the otherwise fine situation of this establishment, devoted to artistic photography. In all the rest it has secured a position, as Artemus Ward remarked, "ekalled by few and surpassed by none."

Entering by the carriage way, the entire arrangements are on the ground-floor level, there being abundance of space. The studio proper has been treated with a double-ridged roof, the area (32 × 28 feet) being so arranged that it can be made into two by means of a curtain. The lighting is from north and east. Adjoining this is the artistic workroom, which has ample desk and studio accommodation for many artists, the north light being here utilised. The comforts of the lady artists are fully attended to, there being cloak-rooms, lavatory, dressing-rooms, and so forth. In the dark room, which is also used for the enlarging apparatus, there is ample room for moving about, the space being about 26 × 22 feet, with similar great height of ceiling as the artists' room has, at least fifteen feet. The enlarging apparatus, of which there are at present two, are upon the floor level, and arranged to focus by sliding on rails, fixed in the cemented water and damp-tight floor, so that any enlargement up to four and a half feet in height can be made easily, the workers moving about in the large, well-heated and lighted *camera obscura* as in a large hall, the light being non-actinic. For such sizes, as, indeed, for all large increments, the much belittled, derided, but best of all processes for this kind of work, the old wet collodion, only is used. The size of the baths and the treatment of plates where feet are measurements in place of inches may be imagined by the workers of hand cameras of quarter or half-plates, and will be described more fully later on. In addition to the arrangements for coating such large plates, what may be called the permanent structures must be noted. The developing sinks or trays are in proportion to the plates, and are built entirely of seasoned teak wood. The water supply, which is almost pure, is practically illimitable, and, by skilled plumbing arrangements, so arranged that the operator can have at will either a few drops or full force from the main stream, which supplies Edinburgh, and this, by rose jets, is passed over the plates almost as fine as spray by the operator, or fuller if desired. The drainage, which is as essential as the supply, has been most carefully managed, separate outlets being arranged for the catchment of the necessarily large amount of silver waste and of the much greater quantity of washing waters, and free ventilations of both systems has been fully provided for.

One feature of all the drainage pipes are claimed by the sanitary

engineers, who have carried out this work, as being perfect. They are glass coated internally and externally to prevent corrosion, but that must be taken *cum grano salis*, the different expansions of glass and metal, or any other material, must ultimately result into cracks, into those cracks the waste chemicals will seek a way, and so they may be after all only what time will prove. The intentions have been of the best; the saving appliances will of themselves pay new sets of pipes, so perfect are they.

In the operating room with large plates, the fixing of which is by cyanide of potassium, there is always the difficulty of the emanation from it, and its effects on those engaged in the work. This is reduced to its minimum by using dipping baths and those kept so far covered, as well as by the efficient system of ventilation adopted.

The printing department is quite as fully equipped, the sensitising rooms for silver platinum and carbon, communicating by sliding doors, the drying rack, sliding up in the air out of the way of the workers or of dust. The temperature, which is carefully regulated throughout, is maintained by hot water pipes. Where deemed necessary, as in the case of acid solutions, slate sinks are adopted, as is also lead, where that metal is deemed most suitable, as in the case of cyanide. A very useful arrangement for the drying of gelatine negatives, is a large sheet iron stove, suitably racked for different sizes, and capable of regulation to any desired heat, gas jets being used for this purpose with a free circulation of air.

This paper has extended to too great a length to admit of lucid description of the cameras, enlarging apparatus, and the tools and apparatus therewith connected which are of special interest, and so must be left for another occasion. The architects, Messrs. M'Arthy & Watson, who seem to make a speciality of this class of structure, have great credit in designing and carrying out a very perfect photographic artist's workshop.

THE CHICAGO EXHIBITION

GENERAL REGULATIONS FOR FOREIGN EXHIBITORS.

1. The Exhibition will be held on the shore of Lake Michigan, in the City of Chicago, and will be opened on the 1st day of May, 1893, and closed on the 30th day of October following.

2. All Governments have been invited to appoint commissions for the purpose of organizing their departments of the Exhibition. The Director-General should be notified of the appointment of such foreign commissions as soon as the appointment is made.

Diagrams of the buildings and grounds will be furnished to the foreign commissions on or before January 1, 1892, indicating the localities to be occupied by each nation, subject, however, to revision and re-adjustment.

3. Applications for space and negotiations relative thereto must be conducted with the commission of the country where the article is produced.

4. Foreign commissions are requested to notify the Director-General not later than June 1, 1892, whether they desire any increase or diminution of space offered them, and the amount.

5. Before November 1, 1892, the foreign commissions must furnish the Director-General with approximate plans, showing the manner of allotting the space assigned them, and also with lists of their exhibitors, and other information necessary for the preparation of the official catalogue.

Products brought into the United States at the Ports of Portland, Maine, Boston, New York, Philadelphia, Baltimore, Tampa, New Orleans, San Francisco, Wilmington, Portland, Oregon, Port Townsend, Wash., Seattle, Wash., Tacoma, Wash., and Chicago, Ill., or at any other port of entry, intended for display at the International Exhibition, will be allowed to go forward to the exhibition buildings, under proper supervision of customs officers, without examination at such ports of original entry, and, at the close of the Exhibition, will be allowed to go forward to the port from which they are to be exported. No duties will be levied upon such goods, unless entered for consumption in the United States.

6. The transportation, receiving, unpacking, and arranging of the products for exhibition will be at the expense of the exhibitor.

7. The installation of heavy articles requiring special foundations or adjustment should, by special arrangement, begin as soon as the progress of the work upon the building will permit. The general reception of articles at the Exhibition buildings will commence on November 1, 1892, and no articles will be admitted after April 10, 1893.

8. Space assigned to foreign commissions, and not occupied on the 10th day of April, 1893, will revert to the director-General for re-assignment.

9. If products are intended for competition, it must be so stated by the exhibitor; if not, they will be excluded from the examination by the international juries.

10. An official catalogue will be published in English, French, German, and Spanish. The sale of catalogues is reserved to the World's Columbian Exposition.

The twelve departments of the classification which will determine the relative location of articles in the exhibition (except in such collective exhibits as may receive special sanction), also the arrangement of names in the catalogue, are as follows:—

A. Agricultural, Forest Products, Forestry, Machinery and appliances.
B. Viticulture, Horticulture, Floriculture.
C. Live Stock: Domestic and Wild Animals.
D. Fish, Fisheries, Fish Products, and Apparatus for Fishing.
E. Mines, Mining, Metallurgy.
F. Machinery.
G. Transportation: Railways, Vessels, Vehicles.
H. Manufactures.
J. Electricity.
K. Fine Arts: Pictorial, Plastic, and Decorative.
L. Liberal Arts: Education, Engineering, Public Works, Architecture, Music, and the Drama.
M. Ethnology, Archæology, Progress of Labour and Invention, Isolated and Collective Exhibits.

11. Foreign commissions may publish catalogues of their respective sections.

12. Exhibitors will not be charged for space.

A limited quantity of steam and water power will be supplied gratuitously. The quantity of each will be settled definitely at the time of the allotment of space. Any power required by the exhibitor in excess of that allowed will be furnished by the World's Columbian Exposition at a fixed price. Demands for such excess of power must also be settled at the time of the allotment of space.

13. Exhibitors must provide, at their own cost, all show-cases, shelving, counters, fittings, &c., which they may require, and all countershafts, with their pulleys, belting, &c., for the transmission of power from the main shafts in the building where the exhibit is located. All arrangements of articles and decorations must be in conformity with the general plan adopted by the Director-General.

Note.—The general plan requires all decorations, signs, &c., to be in harmony with the dignity and magnitude of a magnificent exhibition, and the Director-General is empowered to secure this result.

The World's Columbian Exposition will take precautions for the safe preservation of all objects in the Exhibition, but it will in no way be responsible for damage or loss of any kind, or for accidents by fire or otherwise, however originating.

Note.—A thoroughly equipped fire department will protect the buildings and exhibits, and a large police force will maintain order. The entire Exposition grounds will be under the immediate supervision of the City of Chicago and of the State of Illinois. A guard, equal to any possible contingency, is thus provided, the municipal authority being upheld, if necessary, by the State troops, and the State by the army of the United States, so that no apprehension need arise as to losses resulting from lawlessness.

14. Favourable facilities will be arranged by which exhibitors or foreign commissions may insure their own goods.

Note.—Special care has been taken to render everything about the Exposition as nearly fire-proof as possible; and it is reasonably certain that the rates of insurance will not be excessive, but, on the contrary, very reasonable. Exhibitors may insure in any company, foreign or domestic. Arrangements will be made with English, French, German, and American companies to fix uniform or special rates on exhibits and buildings; so that no advantage will be taken of any exhibitor who wishes to insure his goods.

Foreign commissions may employ watchmen of their own choice to guard their goods during the hours the Exposition is open to the public, subject to the rules and regulations of the Exposition.

15. Foreign commissions, or such agents as they may designate, shall be responsible for the receiving, unpacking, and arrangement of objects, as well as for the removal at the close of the Exposition; but no person shall be permitted to act as such agent until he can give to the Director-General written evidence of his having been approved by the proper commission.

16. Each package must be addressed "To the Commission (name of country) at the World's Columbian Exposition, Chicago, United States of America," and should have at least two labels affixed to different, but not opposite, sides of each case, and give the following information:—

17. (1) The country from which it comes; (2) name of firm of the exhibitor; (3) residence of the exhibitor; (4) department to which objects belong; (5) total number of packages sent by that exhibitor; (6) serial number of that particular package.

18. Within each package should be a list of all objects.

19. If no authorised person is at hand to receive goods on their arrival at the Exposition buildings, they will be removed without delay, and stored at the risk and cost of whomsoever it may concern.

20. Articles that are in any way dangerous or offensive, also patent nostrums and empirical preparations, whose ingredients are concealed, will not be admitted.

21. The removal of goods on exhibition will not be permitted prior to the close of the Exhibition.

Note.—Articles not on exhibition for competition may be sold under special permit.

22. Sketches, drawings, photographs, or other reproductions of articles exhibited will only be allowed upon the joint assent of the exhibitor and

the Director-General; but views of portions of the buildings may be made upon the Director-General's sanction.

23. Immediately after the close of the Exhibition, exhibitors shall remove their effects, and complete such removal before January 1, 1894; goods then remaining will be removed and sold for expenses, or otherwise disposed of under the direction of the World's Columbian Exposition.

24. Each person who becomes an exhibitor thereby acknowledges and agrees to be governed by the rules and regulations established for the government of the Exhibition.

Special regulations will be issued concerning the exhibition of fine arts, awards, the organization of the international juries, and sales of special articles within the buildings, and on other points not touched upon in these preliminary instructions.

25. All communications concerning the Exhibition will be addressed to the Director-General, World's Columbian Exhibition, Chicago, Illinois, U.S.A.

The management reserves the right to explain or amend these regulations, whenever it may be deemed necessary, for the interest of the Exhibition.

—*Journal of the Society of Arts.*

The following articles were received too late for the Almanac:—

A SIMPLE COPYING STAND.

By Thos. Boxell.

In rebuilding my studio last year, I found I could not copy pictures at one corner only (as I had been in the habit of doing in the old studio) without a flare on them, unless done at one particular time of the day. I therefore hit upon the following very simple plan, viz.:—I got a piece of board very similar in shape to a cricket bat, but, of course, flat, the handle of which I inserted into the bottom half of the head rest, which, as may be supposed, can be placed at any angle from the light, raised up or down, and is as firm as a rock. On the bat I have a ledge, where the photograph to be copied rests, which is held in its place by a piece of glass larger than the photograph, which also rests on the ledge, and is fastened at the top by a button similar to those used to fasten cupboard doors. There is, therefore, no damage done to the original photograph by the use of pins or tacks, and they can be changed with great rapidity. I ought also to state that the bat is held firm by the ordinary screws of the head-rest, and when the copying is done the bat is taken out and the head-rest used as usual.

ON FERROCUPRIC RED-BROWN PRINTS AND EASTMAN'S TRANSPARENT FILMS.

By G. A. Kenyon, M.B. (Lond.)

By way of contribution to the Almanac, I should like to put on record my experience with—

1. Eastman's transparent film. This I find simply perfect for small negatives for enlargement. Other transparent films are too thick; but this can be enlarged from as easily as glass, and definition is very good, owing to the fineness of the deposit. For want of practice, I have not yet quite overcome the difficulties arising from the cockling of the film in the developer, so as to make a perfect result a matter of certainty, but this is only an affair of time. And,

2. As to the exquisite beauty of the results obtainable by the Obernetter's ferrocupric process described at page 365 of The British Journal Photographic Almanac for 1889, which I demonstrated before the Liverpool Photographic Association this summer. The description given is rather inadequate; perhaps it was good luck enabled me with perseverance to get proper results, which were of a fine reddish-brown colour, very desirable, and of most exquisite detail; although done on common writing paper, there was no sinking in, and absolutely no loss in fixing, so that a magnifying glass could be used to render visible the finest and most minute points. The only drawback, the slowness of the printing, except in direct sun with clear negatives, was entirely overcome by using cold platinotype, *i.e.*, ferric-oxalate paper; only then an increased amount of sensitiser had to be added to the developer to make up for the absence in the paper of copper salts, with the result that the lights became slightly muddy, which spoiled the beauty.

The special point in which the description fails is the omission of any statement of the fact that during the washing after development the image entirely disappears, and one might think it was lost; but it comes back when placed in the solution of ferridcyanide of potassium.

A "ROCKER" WORKED BY A PENDULUM.

By W. K. Burton (Tokio.)

I see that, some time ago, there was a discussion at a meeting of the London and Provincial Photographic Society about "rockers;" or, to speak more correctly, it was suggested that there should be a discussion, but the only result was that Mr. A. Mackie humorously remarked that "the first rockers worked beautifully, but only with an empty dish."

Taken "humorously," I think Mr. Mackie's remark is very true. In other words, it is wonderful how a few ounces of developer in a dish "deadens" any rocking motion that is not very energetic, or extremely slow. A heavy pendulum, for example, with a top piece in the form of a small table for holding the developing dish, may swing for an hour, either unloaded, or with an empty dish, say, 12 × 10, but let a few ounces of developer be poured into the dish, and it is astonishing how few seconds it will take for the pendulum to come to rest, unless it is extraordinarily heavy, and is also very long.

I have had some experience with "rockers" of the kind mentioned—the simplest possible kind. I set up the first one two or three years ago. It consisted of a twelve-pound shot at the end of a pendulum three feet long, hung over a bit of an old Japanese sword-blade as a knife-edge. It was so frictionless that it would swing for more than an hour unloaded, yet if a 12 × 10 dish were placed on it, and ten ounces of water were poured into the dish, the pendulum would be completely at rest at the end of twenty seconds. It was therefore of very little use.

I gave a little thought to the matter, and, with a few experiments, found out that the "deadening" action varied greatly with the size of the dish, but principally with its length in the direction in which the wave passed. Thus, if the 12 × 10 dish were so placed that the wave passed across it, the pendulum would swing twice as long as if the wave passed along it. I further found that, if the period of swing of the pendulum corresponded to the wave period of the bath, the deadening action was reduced to a minimum, and that it was much less if the pendulum period were longer than the wave period than if it were shorter.

It is impossible to have a pendulum whose period will correspond with those of the waves in different sizes of dishes, and impracticable to have one whose period will even correspond with the wave period in one size of dish, as the period of wave varies with the depth of liquid in a flat-bottomed vessel. It is evident that the only thing to do is to have as heavy a pendulum as possible, and to have as long a rod as is practicable, so that the period will be very slow. It is not likely to be practicable to get a pendulum so long that the period of motion would be too long. A "three-seconds" pendulum is nearly thirty feet long.

My own limit was reached with a thirty-two-pound shot at the end of a rod six feet long, itself weighing about six pounds. I found that with this a 12 × 10 dish was kept in motion from one to two minutes with the wave passing lengthways, nearly three minutes passing crossways, whilst with smaller dishes the time was longer. I think that, with a cabinet dish, the motion will continue for nearly an hour.

I find the arrangement a great convenience. Indeed, I found the first one a convenience, because it is so much easier just to give the pendulum rod a touch now and then than to have to keep the dish in the hand, or even than to have to lift it every few seconds and give it a rock.

To those who want a "rocker," my advice is to get the heaviest mass of metal at hand, and to make the longest practical pendulum with it. Of course, if the pendulum is more than about three feet long, it must pass through the floor.

Our Editorial Table.

The Studio and What to Do in It.

By H. P. Robinson. London: Piper & Carter, Furnival-street, E.C.

We are glad to see a reissue of this standard work. We have already reviewed it, hence there is no necessity for reiterating our high opinion of its excellence.

Rouch's "Excelsior" Hand Camera.

This new hand camera is an evolution of the well-known "Eureka" of Messrs. Rouch & Co., and much ingenuity has been displayed in its construction. While the external dimensions, when packed for carrying, remain the same, it has been made amenable to several improvements of a marked nature. First of all, it is capable of being

focussed, this focussing embracing a range so great as to permit of either of the two lenses with which it is fitted—one of a long, and the other of a very short focus—being used. To do this with accuracy, there is a double graduated scale and index on the top, this adjustment being operated by a rack and pinion. It has also a rising front, the utility of which is well recognised. The shutter is capable of receiving any degree of speed, from the highest to the lowest, including time exposures. It has two finders; and, to sum up, the changing back, which contains twelve plates, can be detached from the camera in the open fields, and another, containing unexposed plates, substituted for it. In this way the supply of plates which may be brought in the field is practically unlimited. The size of the "Excelsior," with a reservoir of plates, is only $8 \times 5 \times 4\frac{1}{2}$ inches.

The Principles of a Photographic Lens Simply Explained.

This pamphlet, by R. & J. Beck, Cornhill, London, forms a reply to questions constantly being asked of the authors by photographers who want to know the most suitable lens for any particular kind of work, and the meaning of the terms angle, aperture, and focus of a lens. The authors treat of pinhole photography, showing that a pinhole has no focus, has unlimited depth of definition, no distortion, and no rapidity. In treating of lenses some excellent and suggestive hints are given, together with a compendious catalogue of the productions of the firm. It may be had free on application.

The Photomnibus.

Under this designation Messrs. Wormald & Co., Sutton, Surrey, have brought out, at the low price of half-a-crown, a photographic camera. Of course it has no lens, a pinhole in front forming a substitute. Still, judging from specimens which accompany the "Photomnibus," it is possible to take fair photographs by it.

We have received from Messrs. Percy Lund & Co. a finely bound copy of Vol. II. of the *Practical Photographer*, printed on toned paper.

RECENT PATENTS.

APPLICATIONS FOR PATENTS.

No. 21,933.—"Improvements in Photographic Lenses." T. R. Dallmeyer.—*Dated December 15, 1891.*

PATENTS COMPLETED.

A New or Improved Printuline Printing Process.

No. 17,484. Edward William Foxlee, 22, Goldsmith-road, Acton, London, W., and Thomas Bolas, 8, Grove-terrace, Chiswick, Middlesex.—*November 4, 1891.*

In the printuline process of photography, as introduced by Messrs. Green, Cross, & Bevan, and now well known amongst photographers, and described in the Specification of Patent No. 7453 of the year 1890, and on pages 657 and 658 of The British Journal of Photography, October 17, 1890, diazotised fabric, paper, or other material, was submitted or exposed to the action of light to obtain any desired impression by placing it, in either a wet or dry state, under the object or design to be printed, and causing the rays of light to pass through or around the latter to the diazotised fabric, paper, or material. According to our invention we dispense with the action of light, and substitute therefor the action of heat, whereby we produce a novel printing process. In carrying the invention into effect we find it convenient to employ a metal plate, stamp, roll, or stencil, either cut by hand, etched, or photographically or otherwise engraved, but other suitable solid substance may be employed, either as engraved plates, blocks, or rolls, or as stencils; in using these plates, blocks, or rolls, we first heat the same, and then press them by any suitable means upon the diazotised fabric, paper, or material, and afterwards we submit the latter to a similar treatment to that used in the printuline photographic process after its submission to light, as described in the above-mentioned publication. In using a stencil we apply heat thereto in any convenient way, such, for example, as by causing a highly heated block or roller to press thereon sufficiently long to cause the change in the diazotised fabric, paper, or material, through the interstices or perforations of the stencil, but not long enough to cause the heat to be transmitted through the solid part of the stencil. Or we employ radiant heat or a current of hot air, gas, or steam to act upon the diazotised fabric, paper, or material through the interstices or perforations of the stencil.

Having now particularly described and ascertained the nature of our said invention, and in what manner the same is to be performed, we declare that what we claim is:—1. The new or improved printuline printing process, substantially as herein described. 2. A printuline printing process in which the action of heat is employed to obtain the impression, substantially as herein described.

Improvements in or Appertaining to Apparatus for Changing the Views in a Magic Lantern.

No. 14,734. Charles William Hudson, B.Sc., York-buildings, Dale-street, Liverpool, Lancashire.—*November 7, 1891.*

This invention relates to certain improvements in or connected with apparatus for changing the views in magic lanterns, its object being to provide means whereby the lens—or, what is the same thing, the luminous field of the screen upon which the views are projected—may be more or less obscured during the changing of the plates or transparencies in the lantern.

In carrying the invention into effect, I arrange, in connexion with the plate carrier or slide, a shield which is adapted to be operated in such manner that, prior to the movement of the carrier to change the view, the lens is obscured, and, during the movement of the carrier, remains obscured, being again placed in an unobscured condition after the movement of the carrier is complete. All these movements of the carrier and the obscuring device are performed in their proper order by the simple movement of an operating lever connected by suitable mechanism to the carrier and shield.

The claims are:—1. In conjunction with the plate carrier of a magic lantern, and with a movable shield for obscuring the lens thereof, mechanism connected with said plate carrier and shield, and so combined and arranged that, during the middle portion of the travel of an operating lever, the lens is obscured by the shield and the carrier operated, while, during the initial and terminal portions of said lever's movement, the shield is moved to respectively obscure and unobscure the lens without a corresponding movement of the carrier, substantially as described. 2. The combination, with the plate carrier and the revolving shield, of the lever movable with the carrier and the operating handle movable with the shield, and so mounted and arranged with respect to said lever that it is automatically coupled to the latter during the middle portion of the stroke and uncoupled therefrom during the initial and terminal portions of its stroke, substantially as and for the purposes described. 3. The improved apparatus for temporarily obscuring the lens of a magic lantern, taken as a whole, and combined and arranged substantially as shown and described.

Cutting Glass Plates by Machinery.

No. 456. William John Wilson, 6, Malden-road, Watford, Herts.—*November 14, 1891.*

My invention has for its object the cutting of glass plates (particularly those intended for photographic purposes) by machinery, whereby the operation is effected with far greater rapidity and precision than by hand, as hitherto practised.

In carrying out my invention, the plates are presented in succession to the cutting tools, and, according to one arrangement, the cutting is effected by the motion of the plate under the stationary tool or tools, which are mechanically brought down and pressed on the plate at the proper time, whilst, in another arrangement the cutting is effected by the motion of the cutting tool or tools over the plate whilst the latter is at rest.

The first arrangement comprises an endless carrier band upon which the plates are laid in continuous succession, and provided with means whereby the plates are gripped or carried along and presented to the action of the cutting tool, the carrier being suitably supported under the pressure of the cutting tool. The latter is a diamond carried on a holder mounted above the carrier, and brought down at the proper moment as each plate comes beneath it, and raised again after completing a cut by a quick-acting mechanism operated from the carrier or from one of its driving rollers, the pressure of the tool upon the plate being regulated by a spring or weight, as many such tools being used as it is required to make parallel cuts at one time.

The other arrangement comprises a rotating table provided with mechanically actuated grippers, or equivalent means, whereby the plates laid upon the table in continuous succession are firmly held when under the action of the cutting tool or tools. The table receives intermittent motion through successive portions of a revolution, with intervening periods of rest, and a plate laid on the table during a period of rest is by the next partial revolution of the table brought into position to be acted on by the cutting tool during the next period of rest. The cutting tool is mounted in a sliding carriage, working on guides above the table in such manner that the tool may be brought down upon the plate, drawn across it, and lifted, after which it returns to its original position during the next partial revolution of the table, in readiness for operating on the next succeeding plate. If the plate is to be again cut at right angles to the direction of the first cut, it is brought by such partial revolution under a second tool, similarly mounted and operated, by which it is cut during the next period of rest, the guides for this second carriage being, of course, suitably arranged in the desired direction of the cut to be made. After the cutting is completed, the grippers release the plate at the next stoppage, and it is removed from the table.

Each carriage may carry as many diamonds as there are parallel cuts to be made at one time, and the carriages may be operated by hand or by mechanical means, from the axis about which the table rotates, or otherwise.

[The full specification is illustrated by five sheets of drawings.]

The next One-man Exhibition at the Camera Club will be devoted to the pictures of Mr. J. Pattison Gibson. The Exhibition opens on Tuesday next.

Intending exhibitors at the forthcoming Chicago Exhibition will do well to peruse the general regulations for foreign exhibitors, which we print on page 11.

We are sorry to learn of the death of Mr. R. Turnbull, of Glasgow, who succumbed to influenza. Mr. Turnbull will be remembered as a prominent member of the Photographic Convention of the United Kingdom. He not long since bought Mr. A. L. Henderson's London business. He was a photographer of very considerable skill, and enjoyed a great deal of success.

To keep unmounted prints flat, Mr. Albert Levy recommends the following method. It is one which he personally employs:—Take a piece of rubber sheet, about three-eighths to half an inch thick, and, pressing the face of the photograph gently down on it with a wooden paper-knife's edge, pull the photograph lightly through it several times, until you obtain the opposite result, viz., a pronounced bend backward. Then lay under pressure for a day or two flat—in a book or under one—and henceforth it will remain flat, unless rolled up again purposely.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

DECEMBER 22—Technical Meeting.—Mr. A. Mackie in the chair.

The CHAIRMAN observed that at a former meeting he had stated that the hypo and potassium ferridcyanide reducer, used for removing the image, always left a deposit in the film. He recently applied this reducer to films for a quarter of an hour, and had then washed them. The films were stained, but the stain was got rid of by further washing. The image could still be seen. With potassium bichromate and sulphuric acid the stain could not be got rid of. He had tried to re-develop one of these plates, but only got a stain over the plate.

Photographs of a spider's web by Mr. H. P. Chandler, as also strips of a plate exposed to a gas flame for geometrically increasing periods, and subjected to various modifications of the developer, to illustrate the different degrees of density obtainable, were exhibited.

Mr. E. W. PARFITT asked the best way to photograph hoar frost on a window pane?

Mr. WILLIAM ENGLAND suggested a piece of black velvet, placed at an angle at the back of the window.

Mr. J. D. ENGLAND said that, to produce the effects desired, it was not necessary to photograph frost, as a great many crystallisable salts could be used to give the same effects.

A number of magnesium flashlamps, including Vever's, Hibbert's, Shew's Fusee (single and continuous flashes), and England's, were then demonstrated, and the meeting terminated.

North Middlesex Photographic Society.—December 28, Mr. J. W. Marchant (President), in the chair.—Mr. J. F. SMITH, F.R.M.S., showed prints from a number of negatives in duplicate on Obernetter and Ilford printing-out paper. In some cases even Mr. Smith could not say which was which; in others the advantage leaned sometimes to one side, sometimes to the other, the general opinion being that the papers were equally good. Mr. Marchant then related an extraordinary experience which he had had. He had made an exposure by gaslight on a vase of flowers, and on developing the plate found it much under-exposed. Having forced the development as far as possible, and the image being barely discernible, he lit the gas, and, taking the plate from the bath, showed it to his son, pointing out the lack of detail. While they were looking at it, a positive image of the son's face appeared on one corner of the plate, about the size of a halfpenny. Thinking it must be a reflection, Mr. Marchant altered the position of the plate, and the lad walked away. Mr. Marchant was astonished to find that the image remained. He showed it to his son, who recognised the portrait, and while they were looking at it the image increased in strength and clearness, until, in a few minutes, the plate fogged all over, and the image was obliterated. The matter was discussed, and as the developer had not been washed from the plate, and bearing in mind the peculiar effects produced in the way of reversal by prolonged exposure, supplementary exposure, &c., it was felt that the mere development of the image, and in a positive form, might be explained if it could be shown how the reflected light from the boy's face came to be converged on the plate. It was suggested that Mr. Marchant's spectacles might have focussed the rays, but the difference in height of the two actors made this improbable. Mr. MARCHANT explained that the plate had been taken from the maker's box immediately before the exposure, could not have been in contact with any negative or print of his own, and, indeed, that no portrait in the same position existed. The matter was voted a mystery, and explanations are invited. Mr. H. SMITH called attention to the new developer "Rodinal," and a short discussion followed.

South London Photographic Society.—December 21, Mr. F. W. Webb in the chair.—The evening was devoted to the explanation and demonstration of various "printing processes." The Autocopyist Company, London-wall, E.C., first gave a demonstration of their method of easily producing a large number of permanent prints. Prints in platinum (the President), silver (Mr. Herbert), and bromide (Mr. Whitby), from a 12×10 negative of Shanklin Chine, were then compared and examined. Mr. HERBERT said it was always his practice, in silver printing, to salt the paper before toning in a bath containing one ounce of salt to a pint of water, as it produced more brilliant prints. The prints were then washed twice in water, and toned in a borax bath—half a teaspoonful of borax to a pint of water. The quantity of gold required varied with the brand of paper used. The toning action was stopped by placing the prints in water. As a preventive of blisters, he used a fixing bath made as follows: Two ounces of hypo, dissolved in perfectly cold water, and a teaspoonful of borax in half a pint of warm water, the two being mixed together before using. Mr. MILLER said he always used a few drops of ammonia for the same purpose. It also assisted in washing out the hypo. Mr. WHITBY, in explaining the method of printing on bromide paper, said that he considered it possessed advantages over other methods of printing. To get rid of any yellow stain which might be left after development and washing, he used a strong solution of tartaric acid. Prints could be reduced in a dilute solution of chloride of lime. Fading was the result of insufficient washing.

Bath Photographic Society.—December 17, Mr. W. Pumphrey in the chair.—Mr. HEDLEY M. SMITH discoursed on the Kodak form of hand camera, explaining fully the working details of the several instruments bearing that name.

DECEMBER 18.—The members of the Society filled the lecture programme of the Literary and Philosophical Association. The CHAIRMAN (Mr. W. Pumphrey) said the Society felt honoured in being requested to fill up that evening with matters of photographic interest. In the first place, Mr. P. Braham would photograph a microscopic object, and explain the method of doing so. Then he (the Chairman) would exhibit on the screen a series of photographs taken by him in the North of Ireland last September. The Chairman then referred in detail to photographs exhibited by Messrs. Appleby, Dugdale, Lambert, Lewis, Perren, Powell, Payton, Howe, Wells, and himself, which were displayed for examination.

Glasgow and West of Scotland Amateur Photographic Association.—December 24, Mr. John Morrison, jun. (President), in the chair.—The office-bearers for the ensuing year were nominated, and Mr. William Goodwin (Hon. Secretary) read a paper on *Lenses*.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

THE PHOTOGRAPHIC SOCIETY.

To the EDITOR.

SIR,—To Mr. Mackie's last handful of mud, as far as it concerns myself, I have only a short reply. He says I used certain words on a certain occasion, and spoke one of them in italics. I say that I did not, and could not have used them, therefore it is reduced to a matter of veracity between him and me. I am content to leave it there. My reputation is quite safe in the hands of photographers.—I am, yours, &c.,

Tunbridge Wells, December 26, 1891. H. P. ROBINSON.

To the EDITOR.

SIR,—There is one part of Mr. Chapman Jones's letter, which appears in your last issue, which ought not to be passed without notice, as it appears not to accord with the sense of what that gentleman said at the meeting of the Society on the 8th inst. At that meeting Mr. Jones was asked if he could support the view that the scandal, that Mr. Robinson had suggested places of honour for his own pictures, did not take place. His reply, apparently somewhat reluctantly given, was that it was impossible for him to say that it did not take place. He further admitted that Mr. Robinson said that he should like his pictures hung at a certain spot, thus supporting the *gravamen* of the charge made against Mr. Robinson. Mr. Jones now says that, if any extraordinary speech had been delivered in his hearing, he should have noticed it, and he regards the decisive statement attributed to Mr. Robinson as extraordinary. As the decisive statement referred to and Mr. Jones's own statement differ only as to the reason assigned by Mr. Robinson for his request, Mr. Jones is apparently leading us to understand that he is able to draw an impossibly minute distinction between ordinary and extraordinary, in a matter in which he avowedly cannot trust his memory, but in reality he is attempting to discredit by implication a statement which he dare not contradict.—I am, yours, &c., ALEXANDER MACKIE.

3, *Upper Baker-street, N.W., December* 28, 1891.

To the EDITOR.

SIR,—Editors—as you, of course, are aware—are a long-suffering race; they have much to put up with, so have their readers; but the line should be drawn somewhere. For more than three months the "P. S. G. B." incident, as it has been called, has occupied valuable space in most photographic journals, and scores of letters and paragraphs have appeared on the subject. The half-dozen gentlemen immediately concerned may take some interest in the matter; but I put it to you, Mr. Editor, with all submission, candidly, now, don't you think the generality of your readers have had nearly enough of it? The "incident" itself was a very trivial matter, and reflects credit on nobody concerned. Besides, the old lady in Great Russell-street has solicited all the photographic societies to become affiliated with her, and, more curiously still, sixteen have already consented to be received into her maternal bosom. Several others are hanging aloof, wisely waiting to see what is to be gained by their union with a Society which makes such a muddle of its own affairs and don't apparently understand its own rules and bye-laws.

The more this correspondence is prolonged, the less respect will be felt for the Society and those responsible for its management. The "incident" was regarded by many as a good joke at first, but the fun has been washed out of it long ago. Please, therefore, Mr. Editor, *draw the line*, and let me conclude, as our old friend Sam Weller did on a memorable occasion, with a "werse:"—

Oh, please, Mr. Editor, stop it,
We're sick of the subject, so drop it,
And each letter you get from this quarrelsome set
In the waste-paper basket, please "flop it.'

—I am, yours, &c., DROP SHUTTER

December 29, 1891.

BLISTERS.

To the EDITOR.

SIR,—Anent the remarks on blisters in your last issue by Mr. W. B. Bolton, the use of a weak hypo bath is given as a sure preventive of blisters, and not a risky one as to their permanency. Many years ago a paper was read before the Photographic Society of Great Britain, in which the author demonstrated that, to ensure *absolute* permanency, each print must be fixed separately in fresh hypo solution. This may be theoretically correct, but actually impracticable, and in dealing with numbers of prints a plan must be devised to fix them all properly, and a number at the same time. The danger of using a weak hypo bath is that, at any rate, the last prints treated are more likely to be only partially done; but, setting aside this reason, a weak bath, long applied, is different in its action to a stronger one for a shorter time. Mr. Bolton, as a clever experimenter, is aware of this, and, in treating a batch of prints, I am afraid those fixed in a weak bath would hardly hold their own as regards permanency with others fixed in a stronger one.

Often a fair degree of permanence is obtained under conditions that would indicate rapid deterioration. Why they remained unchanged for a considerable period can only be attributed to the use of strong solution to start with, as in the case I allude to; the same solution of hypo was used day after day, until it was quite discoloured—I may say black—and the prints had a few changes of water, and were then considered finished so far as fixing and washing went. Permanency seems to depend much more on the thorough solution of the silver salts out of the prints than washing afterwards. The prevention of blisters is the point at issue; as with Mr. Bolton, I find sometimes that reducing the strength of the hypo would ameliorate the trouble, but again it would have little or no effect. My experience has been chiefly with home-sensitised paper, and I feel convinced that the cause is in the preparation of the paper *before* it comes into the hands of the *sensitiser*.

I have occasionally seen blisters on the prints in the *toning bath*, but only a few times, which, at any rate, is sufficient to prove that the different density of the solutions cannot be the cause, the toning bath varying so little from the plain washing water. I have tried, at one time or another, every plan I have seen suggested, sometimes with apparent benefit, and again without any. The device of Mr. Richmond of putting the *dry* prints directly out of the printing frames into a bath of methylated spirit has, each time I have tried it, had the desired effect; but, of course, it *might not* always answer. Fortunately, blisters are not of every-day occurrence. This plan *differs essentially* from Mr. Stuart's, who *tones his prints first*, before the spirit bath. It will not be until the cause of blisters is *definitely* known that a remedy, if possible, will be found for them; at present we work in the dark, and a cure one day is none another. The probability is they are from different causes, each of which requires separate and distinct treatment.—I am, yours, &c.,

December 29, 1891. EDWARD DUNMORE.

"A NEW DEPARTURE IN PHOTOGRAPHY."

To the EDITOR.

SIR,—We refer to an article on page 3 of the *Daily Chronicle* of 28th inst. as a striking example of what a farrago of nonsense (or worse) non-technical papers make of technical subjects. We enclose copy of our reply to the purely personal parts of the article, and ask you to be good enough to publish it in your columns.

The portions of the article not referred to in our reply are equally ludicrous to the expert reader, and are a delicious (though dangerous) compound of want of knowledge and a too evident desire to puff a friend's goods, which apparently stand in need of that adventitious aid.

If the writer of the article had been "content to puff" his friend's paper, we should have been silent, but when he goes out of his way, and, under the cloak of pretended ignorance, belittles our paper, we cannot refrain from exercising an Englishman's right to hit out from the shoulder.—We are, yours, &c., THE BRITANNIA WORKS COMPANY.

Ilford, London, December 29, 1891.

"A NEW DEPARTURE IN PHOTOGRAPHY.

"The Editor, *Daily Chronicle*.

"SIR,—With your kind permission we would question the accuracy, not only of the above title, but of several statements, made in your issue of yesterday, statements which are not only untrue, but unfair to us as manufacturers, who have won back from the Germans a branch of trade which threatened to leave us altogether.

"When your reviewer generalises on photographic methods, expatiates on the advantages of the photographic paper in question, or quotes trite facts, he is on safe ground; but when he goes on to express any original opinions, his words are open to question.

"On the point of permanency, for instance, he says, 'Absolute permanency cannot, in our opinion, be guaranteed to any print made from sensitive salt of silver.'

"Now, scientific opinion and absolute facts entirely controvert this suggestion. Captain Abney, Professor Burton, Mr. Chapman Jones, and Mr. C. H. Bothamley (the four best photographic scientists we have) have all stated explicitly that, given proper care in manipulation, gelatino-silver prints are practically permanent.

"These opinions of experts are amply corroborated by practical photographers, who for six years have been using this paper in their work; they affirm that 'they never saw a faded print on the paper.' Yet your reviewer says, 'The paper has not been tested by time.' He is either ignorant of well-known facts, or his too evident partiality for Mr. Blackie's paper blinds him to their existence.

"By the way, would it not have been nearer the truth to say that celerotype owes its origin to Mr. Woodbury himself?

"The review goes on to say that 'a fourth paper, the Ilford printing-out paper,' is not described by Mr. Woodbury. We may at once explain that the book under review describes only those papers whose manufacturers paid 5*l.* 5*s.* for advertisement space therein, and that we had no need of such a method of puffing our wares.

"The next statement to which we would take exception is the reference to price. The reviewer says: 'This (Ilford) paper is rather cheaper than the others.' Such a statement is a *suppressio veri*, too evidently intentional, as our paper is less than half the price of its predecessors.

"Of its comparative qualities we would prefer not to speak, it would not be becoming to laud our own wares.

"We are next told that our 'paper is little known.' Here, again, ignorance or partiality has influenced the reviewer; and, taking into account his subsequent laudation of celerotype, it seems probable that partiality is the motive.

"It is true that we have not advertised the paper either in Mr. Woodbury's book or in the photographic journals (and therein, perhaps, lies the cause of the attack on us). If sales, however, indicate popularity, we are more than satisfied; and, if we may be allowed to say so much, we would state that we have never been able to execute all the orders received, so great has been the demand.

"Photographers, professional and amateur alike, are, and have been, keenly alive to the great advantages of gelatino-chloride paper, which is no new thing, but has stood six years' test. The only clog on its wide-spread use has been the question of price; and, now that the photographic public have such a paper at a reasonable price, they have not been slow to avail themselves of it.

"They have taken it up at home here just as eagerly, and as successfully, as their brethren in the United States have taken up similar papers made there. To those who know the trade, the success of this class of paper is phenomenal, and this gives us one more point of disagreement with your reviewer, and leads us to predict with certainty that we have in this paper the printing process of the future.

"As the yearly consumption of albumenised paper totals up to several millions of pounds annually, and as all this sum is in the hands of the German manufacturers, we trust you will consider the question one worthy of a place in your columns.

"If Englishmen can replace this German-made albumenised paper, even to some small extent only, with English-made gelatine paper, England will be the gainer, and those manufacturers who effect this substitution deserve well at the hands of their fellows—photographic and otherwise.—We are, yours, &c.,

"*For the* BRITANNIA WORKS COMPANY, LIMITED,

"(*Signed*) JOHN HOWSON."

[We have referred to this subject elsewhere, and may here say that we treasure the *Chronicle* article as a curiosity of the reviewer's art. —ED.]

THE LANTERN EXPLOSIONS.

To the EDITOR.

SIR,—Mr. A. P. Okell, in his valuable remarks on the Ilkeston explosion is a little too severe on the lanternists who make their final preparations in the presence of an audience. I quite agree with him that no operator of taste and experience would ever do so (*if he could help it*). But what says experience? How often there is not time to finish before the doors are open. Last night I found myself thirty miles from London, the place a chapel, in which I had never shown before, the time before opening one-and-a-half hours, the arrangements for a lantern exhibition largely neglected, and almost everything to be done. Having made local arrangements, I had not taken my screen-frame, so as to minimise carriage, with the result, that the local bungle involved an hour's work in getting the screen fitted up, where, with my own frame, a quarter an hour would have done it. Naturally, by the time the lantern was in place and connexions made, the audience were doing a little concert outside, and the rest had to be done in their presence, to their increased enjoyment. It was sad, I know, and I felt it more than anybody else; but is not this a common case? If we could get into rooms as early as we liked, and have plenty of time for preparation, the public would have no share in the getting ready, to our own great comfort and ease in the after-working; but we have to do the best we can.

In Mr. Scattergood's case it should be remembered that all the arrangements, adjustments &c., had been made and tested the night before, and he had no reason to suppose that anything more was needed than just to light up and go ahead.

Censure the lantern men as much as you like for not being ready beforehand, but be just in the censure.—I am, yours, &c. ONE OF 'EM.

December 29, 1891.

MR. J. PATTISON GIBSON AT THE CAMERA CLUB.

To the EDITOR.

SIR,—Will you kindly allow me to state that the eighth of the series of "One Man" photographic exhibitions will be open at the Camera Club on and after Tuesday, January 5? The pictures will be by Mr. J. Pattison Gibson, of Hexham, by whom we shall be favoured with a representative collection of his photographs.

Visitors will be admitted from ten to four by tickets, which can be

obtained from the Hon. Secretary of the club, and from members. The exhibition will remain open about six weeks.—I am, yours, &c.,

Camera Club, Charing Cross-road, G. DAVISON, *Hon. Sec.*
December 24, 1891.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

**** Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," *2, York-street, Covent Garden, London.*

W. A. MEIGH.—The broad side.

WALTON ADAMS.—We are much obliged to you. Kindly let us have the details.

BERNERD.—Place a piece of ruby glass in front of the lantern objective, and use a condenser.

COL. GUBBINS.—The Universal Adapter is, we believe, sold by Fallowfield, of Charing Cross-road, and other dealers.

J. C. S.—The address of Mr. J. A. Furnivel, the maker of the micro-projector, is 5, Kay-street, Ardwick-green, Manchester.

INFORMATION.—The prints are produced by the carbon process. Apply to any house which makes that process a speciality.

SOMERSET.—You do not give the quantity of pyro employed. State the complete formula, and we may be able to assist you.

LANCELET L. HASLOPE.—"Rodinal," which is sent out in a very high degree of concentration, would probably suit your purpose.

T. W. THORNTON.—Our special representative unfortunately disappointed us. Your letter came too late for us to do as you suggested.

F. BRYANT.—Apply a solution of mercuric chloride with a brush, and then blacken with ammonia. Other intensifiers may be used in the same way.

J. H. BALDOCK.—If the salts dissolve in hot alcohol, sensitise with a hot solution of silver nitrate, and the trouble will in all probability disappear.

E. LLOYD JONES, of Sale, near Manchester, wishes to know if there is a possibility of his hiring a lantern near Carmarthen, Haverfordwest, or Pembroke, for a lecture he is to give at Tenby.

R. MC. F. M. writes: "Regarding the lantern accident of Mr. Scattergood's, I will simply call your attention to your issue of February 18, 1870, page 81. Perhaps it may shed some light on this much-debated subject.

E. BLAKE.—Excellent enlargements on bromide paper may be, and are constantly being, made with a lantern having only a paraffin oil lamp. We refer you to the advertisement columns of the JOURNAL and ALMANAC.

A. MUNDT writes: "I am desirous of getting an American weekly publication in connexion with the lithographic and collotype trades, and I would be obliged if anybody could name one, with the publisher's name and address."

A. Z.—The cause of the frilling was that the developing and fixing solutions were made too warm. Although in exceedingly cold weather it is advantageous to warm the solutions, they should not be made of a higher temperature than they are when working under ordinary conditions.

PUCK.—Scenes on the stage, with the actors, have been photographed over and over again. "Snap shots" with a detective camera with a lens working at *f*-11 are, however, not likely to be a successful, unless the light be *exceptionally* brilliant, and the plates *exceedingly* rapid, and specially sensitised for the yellow rays.

W. C. asks how, as it is said not to be safe to use gauges, one is to know, when he has his cylinder filled with oxygen, that he gets full measure?—If he cannot trust those who supply the gas, he has a check by weighing the cylinder. By its weight the approximate quantity of the gas it contains can be ascertained.

R. A. W. complains that his studio windows are continually being broken maliciously by, he suspects, one of his neighbour's boys, though he cannot detect the delinquent. He asks how we should advise him to act?—We should see the superintendent of police in the district, and state his suspicions, and the reasons for them. The annoyance will then probably cease.

ALEX. MCC.—For photo-lithography, gelatine negatives are not so suitable as those by wet collodion. It is a *sine qua non* that the lines are represented by clear glass without veil. This is rarely the case with dry plates, except those supplied by one or two firms, specially made for photo-mechanical work. Messrs. Mawson & Swan and the Autotype Company supply such plates.

DOUGLAS M'NEILL.—If you copy a single picture by a binocular camera the result will not be stereoscopic, but it is possible to trim two similar pictures and so mount them that when viewed in the stereoscope they shall appear as if they stood quite outside of the mount. The principles of this will be found described in the editorial article of our ALMANAC for 1887, to which we refer you.

H. D. BERTALT.—The discrepancy in the measurement of the iris diaphragm arises from the values of the apertures being engraved on the mount without each lens being carefully measured. The difference may not have existed in the case of the lens which formed the sample given to the engraver, but a difference in the density, and consequently in the curves of the others which were placed in the previously engraved mounts, will account for the discrepancy.

C. WILKINS.—The mere fact that the view has been photographed before, and the photograph made copyright, does not prevent you, or any one else, from photographing it again, even from exactly the same spot. The copyright is in the photograph, and not in the scene.

W. W. RANDALL writes:—"When a pyro-developed plate is not *thoroughly* washed, and is then put into the alum bath, it will often show a flash of phosphorescence, lasting sometimes for a second. It always occurs to me when I do not wash plate *well*. A friend of mine also has the same experience. The place where the alum tray is set must be rather dark, otherwise the phenomenon cannot be seen. Can any of your readers tell me the reason thereof?"

T. BEDWELL asks if the methylated spirit now being sold under the new Excise regulations is suitable for making collodion with for enamelling silver prints, and whether the mineral naphtha is likely to act injuriously on the photographs?—We should imagine that the spirit would answer quite well, though we have not actually tried it for this particular purpose. It would be very unlikely that the presence of such a minute quantity of mineral spirit would have any influence on the permanence of the print.

S. B. E. says some years ago he was "shown a portrait, or, rather, two portraits, of a man playing chess with himself—that is, the same man was seated on either side of the table, apparently playing the game, and there was no appearance of joining or masking in of the second figure, it was so neatly done." He wishes to know how it was accomplished.—Such pictures were very common many years ago, and are easily taken. Apparatus for the purpose is described by Mr. T. Gulliver on page 655 of the ALMANAC.

AMATEUR (N. W.) asks how to prepare a background in "size colour," of an even slate colour, such as those often seen in professional studios?—Mix lampblack and whiting together in water into a thin paste, to the colour desired. Then add sufficient hot "patent size" to form a tremulous jelly when cold. Apply in this state with a whitewash brush. As the colour dries of a different tint from what it appears when wet, it is a good plan to apply a little to one corner first, and allow it to dry, in order to see that it is right before going over the whole, or the work may possibly have to be done a second time.

G. E. S. writes: 1. Can you recommend me a good mountant for fixing bromide prints to mounts which I want to have bound eventually into an album. I have tried starch, which is nice and clean, but the mounts "buckle" so much in drying that it seems doubtful to my mind if that is the best thing to use. I may add, that mounting on both sides of the card does not counteract the evil. 2. Do you think, in a collection of views of a single district, that mounting on both sides of the mount detracts from the interest and character of the work, or would you advise mounting on one side only? 3. Can you tell me anything about Watkin's exposure meter? Is its action simple and reliable, and quickly ready? Is the instrument for copying and enlarging also available for landscape negative work? 4. I should like to see a model design for an amateur's dark room to work, say, 12×10. Has this ever been published?—1. Starch is as good as anything. A solution of gelatine, in which alcohol is made to take the place of part of the water, is excellent for avoiding cockling. As the prints have to be bound into a volume, would it not be better to let the binder do the mounting, in which line he is experienced? 2. Usually such pictures are mounted on one side of the mount only. 3. Yes. 4. Several designs have appeared in back volumes of the JOURNAL and the ALMANAC, but most amateurs prefer to design, and fit their own dark rooms, according to their individual tastes and requirements.

PHOTOGRAPHIC CLUB.—January 6, *The Various Applications of Film Negatives.* 13, *Glass amongst the Ancients.*

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—January 4, Beginners' Night; *Paper and Demonstration on Developing*, Mr. F. W. Webb.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—January 7, a paper on *Some Recent Exhibitions*, P. H. Newman. Visitors invited.

NORTH LONDON PHOTOGRAPHIC SOCIETY, Wellington Hall, Islington.—Tuesday, January 5, at a quarter past eight, Technical Night. Visitors are invited.

CROYDON MICROSCOPICAL AND NATURAL HISTORY CLUB (PHOTOGRAPHIC SECTION).—1892: Friday, January 1, *Apparatus and Backing Plates*, W. R. Baker. 8, *Further Hints on Toning Bromide Prints*, John Weir Brown. 15, Extra Lantern Night. 22, *Hand Camera Work*, J. Sinclair. 29, Lantern Night. February 5, *Bromide Enlarging*, J. H. THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1653. Vol. XXXIX.—JANUARY 8, 1892.

A FALLACY IN CONNEXION WITH THE CURTAILMENT OF EXPOSURE.

From the earliest days of photography expedients have been attempted and methods put forward for the purpose of shortening the camera exposure; but, so far as we are aware, not one of them has proved a success, or established a just claim to have effected what was intended. Auxiliary exposure, that is to say, the submission of the plate before or after its exposure in the camera to the action of very feeble light, with or without the interposition of coloured screens, has at various times found supporters even amongst practical men, and has formed the subject of at least one patent; but, though under certain circumstances an apparent advantage may seem to be gained, the effect may be, perhaps, best described by the term applied to it, "judicious fogging," though with some doubt upon the adjective.

Some few years ago Mr. W. K. Burton and Mr. W. E. Debenham exploded the idea of the utility of auxiliary exposure by means of sensitometer experiments, which showed that though a gelatine plate, that had been exposed to a light so feeble as not to produce visible fog, might show one, or, perhaps, two higher figures on the sensitometer than without the preliminary exposure, they possessed no printing value, and the effect was so slight as to make no practical difference in the sensitiveness of the film. It is just possible that in the case of subjects comprising masses of heavy shadow this preliminary fogging may render visible in the negative a certain amount of feeble detail not otherwise obtainable, and this is the class of example invariably selected, in conjunction with a brief exposure, by promoters of the various processes to which we have alluded; but there it ended, for, though a negative of black velvet drapery might by the aid of auxiliary lighting show more detail than one exposed in the ordinary way for the same time, there would be little, if any, difference on the prints; and where the same amount of detail was produced by a shorter exposure the printing result would be inferior.

Auxiliary lighting was, in fact, only intended to help out very short exposures, especially in portraiture, when our films were much less rapid than they are now, and it was scarcely, we believe, claimed to have any value in materially shortening the time of exposure under normal conditions. The fallacy we now propose to expose is of a different character, and is supposed to be of use in cases where abnormally long exposures are requisite, as, for instance, in photographing interiors where the incipient fog set up by the other methods would under any circumstances be useless. It consists in making a portion of the exposure with a comparatively small stop, and the remainder with a larger or the full aperture of the lens.

The idea is that, by using the small stop for a portion of the time, definition is secured and indelibly fixed upon the plate, and that what is wanting in the way of light, to complete the details of the picture, may be supplied by a flood of light for a short period through the full aperture of the lens. But this supposition overlooks the fact that the sharp image obtained by the partial exposure with the stop is too feeble to stand alone, or to assert itself in opposition to the blurred image given by the full aperture, unless, indeed, the proportion of light that reaches the plate through the stop is much in excess of the full aperture, in which case the advantage is not very palpable. Moreover, the method is only practicable to any extent when using a lens of the rapid rectilinear type, and these are not invariably applicable in the case of interiors. With lenses of the wide-angle type, such as the portable symmetrical, there is no necessity for stopping down unless a very wide angle has to be included; and, as the largest working aperture of such instruments gives very satisfactory definition over a considerable area, it will generally be used where at all possible. Even where a smaller stop *must* be used, the difference between it and the full aperture is not great enough to offer any advantage in the use of the latter during a portion of the exposure.

It is true that, under some circumstances, when using a rapid rectilinear, a curtailment of the exposure may be effected in this manner without serious loss of definition, as, for instance, when photographing some object that covers but a narrow angle or a portion only of the plate. Take, for example, a monument or piece of statuary in a dimly lighted edifice, where the surrounding objects are of no importance. Then the full aperture may be used, but it would be preferable to use it entirely, since the construction of the lens enables it to satisfactorily cover the requisite angle; but, where it is necessary to cover the full-sized plate for which the lens is intended definition to the edges can only be obtained by the use of a stop.

The hollowness of the fallacy can be proved by a reference to figures, and we shall detail an experiment that will, we think, make our contention clear, that nothing is to be gained, but rather the contrary, by the adoption of the piecemeal method of working with different apertures. The exposures, it will be understood, are not intended to represent such as would be given for interiors; but, increased proportionately, the principle and result would be the same.

As a starting point, a sheet of printed matter was focussed with a rapid rectilinear lens giving a very flat field, using the stop No. 32 of the Society's standard or f·22·625, under conditions that made an exposure of sixteen seconds about correct, though absolute accuracy in this case was immaterial, as the equivalent exposure can be arrived at mathematically, the object of the experiment being confined to a comparison of the different degrees of definition. In this instance, the definition

was extremely good over the whole plate, which included an angle of about 45°. The next exposure was made partly with the same stop and the remainder with the full-working aperture of *f*-8 or the 4US, the actual light reaching the plate being equally divided between the two, or, in other words, each aperture had similar work thrown upon it. This required an exposure of eight seconds with No. 32 stop, and one second with No. 4, or a total exposure of nine seconds, representing the same effective action of light as the previous one.

But, when examined for definition, the falling off was lamentable, taking into consideration the character of the lens, for, though over a small central area it was as perfect as in the first plate, the loss of sharpness towards the edges was very great. The influence of the small stop was nowhere apparent, so completely masked was it by the action of the fuller aperture, and the result was little, if any, better than if the latter alone had been employed. This will not appear so surprising if it be considered that the larger aperture is free to impress its blurred image on top of the finer definition given by the stop, while the latter is incapable of undoing the work of the other—of, in fact, rendering coarse lines fine when once formed. Such would be possible if the effective exposure given by the stop preponderated considerably over the other; but here they are equal. If such preponderance were allowed, then the gain in time would disappear. Thus, if the relative work thrown on to the two apertures were to be as 3 : 1, the larger share being given to the stop, we have actual exposures of twelve seconds with No. 32, and half a second with No. 4, or a total of twelve and a half as against sixteen seconds with the former alone. But, even with this slight gain, the counterbalancing loss of definition was very considerable.

By calculation we next arrived at the size of stop with which a single exposure would give the same amount of effective light in nine seconds, the time required by the two apertures we have already mentioned, when doing the work equally. This was found to be *f*-17, equivalent to the 18 of the standard series, and a picture taken with this diaphragm as accurately as we could make it, proved almost as satisfactory in point of definition as that produced by No. 32, though, of course, not actually so crisp at the edges. Going a step further, and taking the stop that represents the full working aperture of the series of portable symmetricals, lenses which, as every one knows, work admirably with full apertures over the angle we are working, the definition was scarcely different from the previous exposure, in fact was, for all intents and purposes, perfect, and the exposure was just half of the first one with No. 32 stop, and a little less than two-thirds of that with the work divided equally between that stop and full aperture. One other instance, and we have, we think, proved our case. If the stop *f*-20 be substituted for *f*-22·625 and an exposure of twelve and a half seconds given, a picture showing almost equally good definition will be obtained, and in precisely the same time as when one-fourth of the work is done with full aperture and the definition ruined.

Instances might be multiplied without limit to show that no combination of stops used in the manner described is capable of shortening exposure to any extent without a more than proportionate loss of definition; in fact, the first attempt we made in equally apportioning the work between Nos. 4 and 32, though chosen hap-hazard, as a start, is perhaps the best that could be made. But the definition is inferior to that given by No. 8 (*f*-11·31), with an exposure of four seconds, as against 9.

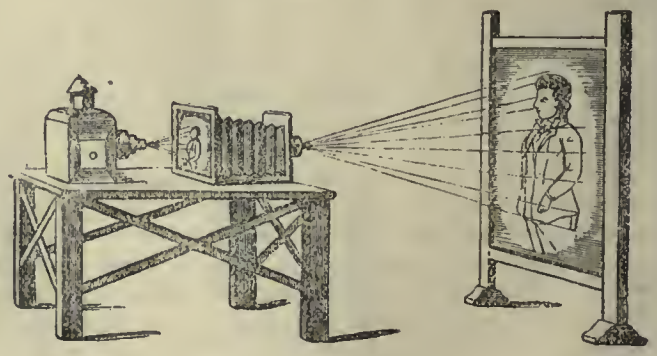
The rapid rectilinear is not a lens that can be used for wide-angle work, otherwise the comparative results would be, perhaps, worse, while the wide-angle lenses, if they afforded facilities for such dodging, do not require it, as they may be used with satisfactory results with full aperture, or nearly so. But the moral is, Give a straight-away exposure with the largest aperture the lens will permit, and the best result wil be obtained.

A SIMPLE ENLARGING ARRANGEMENT.

At a time when enlarging is practised by amateurs to an extent never previously known, it is well that we point out one among several things which may conduce to failure in obtaining the best results. In order to do this, we select as a text on which to hang a few hints the following letter from Colonel Senior, which recently appeared in our Eastern contemporary, the *Journal of the Photographic Society of India*. It is headed "A Simple Enlarging Arrangement:"—

"Supposing an amateur wishes to obtain a bromide enlargement from a half-plate or any other larger-size negative, and has no time to do it by daylight, but has a magic-lantern with a three or four-inch condenser, which, however, is not large enough to enable him to enlarge by the light of the lantern, he may get over the difficulty by using the following simple arrangement:—

"Place the magic-lantern near enough so as to throw a disc of about eight to twelve inches, or more, according to the size of the negative in diameter, on a piece of ground glass placed in front of the negative fixed into the back of the camera, thus throwing a circle of condensed light, which equally illuminates all parts of the negative, and enables the lens in the front of the camera to enlarge the image in the usual manner, thus:—



"If the lantern or room reflects light so as to injure the enlargement, the back part of the camera and magic-lantern should be screened off."

Where the method described by Colonel Senior is defective lies in the fact that the illumination of the negative is good only in and near to the centre, the light becoming so weak as it approaches the margins as to necessitate an exposure many times greater than suffices for the centre. A plate of ground glass is unable to radiate light which falls upon its margins at an angle of such obliquity as that projected from the nozzle of a lantern as shown in the drawing. Without such a ground-glass backing no light whatever would be transmitted through the negative to the enlarging lens but what passed axially or through the centre, while with two or three such plates there would be a greater approach to evenness of lighting at the expense of central darkness.

To rectify this, and assuming that it is requisite that rays of light pass from the lamp throughthe negative in a line as

nearly direct to the lens as possible, the best way would be to place a large lens, one equal in dimensions to the negative, in juxtaposition with it, this lens being of such focus as to condense all the light upon the object-glass or enlarging lens. But this implies the possession of a large condenser, which is not supposed to be on hand at the time.

A good and simple way to get a negative—say, one of half-plate size—well illuminated for either enlarging or reduction, and one by which we have often made lantern transparencies from 8 × 5 negatives, is to discard altogether the lantern shown in Colonel Senior's method, and illuminate the negative by two lamps alone without any condenser at all. As in his system, a ground glass must be placed outside the negative; but the lamps, two in number, must be directed on the ground glass in such a manner as to point to the object-glass, or enlarging lens, the line of direction of the flame being through a portion of the negative about half way between the centre and the margin. The letter < (placed on its side) represents the angle at which the two lamps should be placed, the apex being the lens.

METHYL ALCOHOL *VERSUS* THE NEW SPIRIT.

A CORRESPONDENT this week sends us a suggestion that is worth the consideration of those who are compelled to use methylated spirit, and who distrust the new preparation that has now come into use. It is to employ, in place of it, methyl alcohol, which, in its commercial form of wood naphtha, serves perfectly well most of the purposes for which ordinary alcohol is employed, and which, until now, has been the only addition made in methylating. Its odour is not particularly agreeable to some tastes; but, that little prejudice being overcome, it is consolatory to know that it is readily obtainable, without Excise restrictions, in a sufficiently pure state for most purposes, and at a price not much above that of methylated spirit.

Our correspondent writes chiefly from the point of view of a collodion-worker, and, perhaps, overlooks some of the uses of methylated alcohol beyond his particular boundary, though we are not aware of any special objection to the proposed substitution. Methyl alcohol is perfectly mixable with water, and should therefore be equally available for use in connexion with gelatine emulsion, or in the manufacture of gelatine mounting media. But we are not so sure about its utility for such purposes as the rapid drying of plates, and similar uses, where the strong affinity of alcohol for water rendered it so valuable.

For varnish-making, and as a solvent of the various resins and gum resins, as well as volatile oils, it is every whit as good as alcohol, except for its smell, which, by the way, belongs only to the crude wood spirit, or naphtha of commerce, and not to pure methyl alcohol. It answers perfectly, also, for collodion-making, for which purpose it is considered by some to have advantages over ordinary alcohol. It is, indeed, a perfect solvent of good gun-cotton, without the assistance of ether, and as such was put forward in a suggestive way some years ago.

Though we have not ourselves succeeded in securing a commercial sample that acted as a perfect solvent of pyroxyline by itself, we know it to be at least a partial solvent; but, when combined with a small proportion of ether, its solvent powers become perfect, and the result is a collodion possessing great fluidity and less structure than is usual with ordinary alcohol.

For emulsion purposes it answers well, though it is apt to give a too fluid and slowly setting emulsion, and the "suspending power" of collodion made with it is scarcely equal to that in which ordinary alcohol is employed. This failing is, however, easily remedied by increasing the proportion of pyroxyline; but this, again, constitutes an additional expense.

Though we have used the crude wood naphtha successfully for making emulsion, we should scarcely recommend the practice unless a fairly clean sample is obtainable with certainty. Without, however, going to the expense of the perfectly pure article, which is as costly as ordinary alcohol, a sample of pyroxylic spirit, purified for medicinal purposes, is obtainable at about a couple of shillings the pound.

At any rate, should the new spirit prove objectionable for any of the above purposes, our readers can but try wood spirit.

Fading of Bromide Prints.—The vexed subject of the permanency of silver—and in particular silver bromide—prints came under discussion at the last meeting of the London and Provincial Photographic Association, and formed the theme of some instructive and enlightening remarks by Mr. T. Bolas, which will be found elsewhere. According to his theory, which we may confess strikes us as an extremely feasible one, the fading of bromide prints in a damp atmosphere is due to the presence of sulphate of lime in the paper upon which the prints are made. Under the influence of moisture this substance reacts to form sulphide of calcium, which, in its turn, is converted to hydrogen sulphide. This changes the metallic silver to the state of sulphide, and is itself again resolved into sulphate, and yet once more into sulphide, and so on. As there is not sufficient silver sulphide formed to give a dense image in that compound, the fading of the picture, on this hypothesis, is easily accounted for.

Uranium Residues.—Few photographic societies that we are acquainted with can boast of such a large number of practical and theoretical photographers, able and willing to grapple with the numerous problems that are constantly being brought to light in the progress of photography, as the one just named. Conspicuous among these is Mr. A. Haddon, upon whose *dicta*, as we have before remarked, not only ourselves, but most photographers, look with a great deal of respect. At the meeting above alluded to, Mr. Haddon suggested that, in uranium toning, the spent solution was unnecessarily wasted, inasmuch as, by adding a solution of potassium ferrocyanide thereto, the unemployed uranium could be recovered in the form of ferrocyanide. Mr. Haddon promised, at a future meeting, to give a method whereby the uranium ferrocyanide so obtained may be converted to nitrate. Uranium salts as he remarked, are likely to be employed to a great extent in the near future, and the information he promises will therefore be of much value to many. Experimentalists of the stamp of Mr. Haddon deserve the thanks of the photographic brotherhood.

Coloured Liquids as Light Screens.—The use of various coloured liquids as light screens for the dark room, though, perhaps, the most useful of any light-modifier, is practically inadmissible, owing to the difficulty of obtaining, without great trouble, a convenient receptacle for containing them. There has, however, lately been introduced a series of vessels which, if of sufficient size and not too costly, ought to be just the thing wanted. In a German technical journal a description of the new receptacles is given. They consist of cells with flat sides, made of uniform thickness, and free from bubbles or waviness.

Luminous Flames.—The structure of luminous flames has given rise to many discussions for years past, and at a recent meeting of the Chemical Society a paper was read on the subject. After passing in review the various theories hitherto advanced, the author, Mr. Arthur Smithells, B.Sc., gives what he considers to be a true description of a luminous flame, which it is unnecessary for us here to repeat. But it would not appear difficult, with the aid of orthochromatic plates, to make exact and precise illustrations of the various points of importance by means of photography. Full descriptions of each print could then be given, and a reference made to

the particular photograph illustrating it. Even if the photographs failed to give the luminosity in its true value, the various "sheaths" and forms produced under different conditions could be reproduced in a manner quite sufficient for the argument.

A Simple Flash Lamp, and a Dark-room Lamp.—In the *Scientific American* Mr. George M. Hopkins, under the title of "Suggestions in Photography," brings forward some neat and inexpensive modes of constructing sundry apparatus for photographic workers. There is a magnesium flash lamp. It consists simply of a block of wood, upon which is placed a small tin pan, like an old canister lid. A piece of asbestos is fixed to a wire hasp, worked by a piece of string. The asbestos is charged with spirit, lighted, and, by a pull of the twine, made to dip into and ignite the magnesium powder, which, of course, has to be mixed after some pyrotechnic fashion. He pictures a pasteboard blank with dotted lines, showing where to bend it to make a developing tray. The corners are to be fastened with glue and cloth, and the whole paraffined when completed. Perhaps the neatest piece of apparatus he describes is a portable dark-room lamp. It consists of a two-candle-power incandescent lamp, attached to a handle, and enclosed in a hemispherical reflector, closed at the front with a disc of ruby glass. The lamp is held near the plate. All the light is thrown downwards, so that the eyes receive no light, and are thus free from glare, which prevents due and clear perception of objects. Further, a small portion only of the plate receives light at any time; and, when the lamp is not in use, it can be laid, face down, on the table, or suspended so as to illuminate the dark room.

Another Marvel in Photography.—According to the *Echo*, Captain Colson, of the French *Génie*, has succeeded in photographing without a lens. The apparatus used by the Captain is described as "a simple camera into which the light is admitted by a pinhole." Specimens illustrating the practicability of the method, it is stated, were presented to the Conservatoire des Arts et Métiers one day last week. Our contemporary adds, by way of comment on this important discovery, "Photography has by no means exhausted its stock of marvels, which are revealed one by one to a wondering world." What an interminable mess the non-technical press seem to get into when they touch upon technical matters!

The Vatican Equatorial.—The large equatorial recently installed in the Observatory at the Vatican is under the charge of Father Denza, who is now at work taking photographs in connexion with the universal mapping out of the heavens. One by one the different observatories are getting this gigantic work in hand.

Sketching in Court.—Mr. Justice Denman administered a severe rebuke to some members of the junior Bar whom he noticed making sketches of the witnesses during the trial of the now famous "Pearl Case." Portraits of witnesses in notable cases are required by the regular illustrated papers, and by others who treat their readers occasionally with portraits when a highly sensational case is on. Hitherto we imagined that these were sketched by artists engaged for the purpose, from that portion of the court set apart for the press or the public, and not from that retained for Counsel. Be that as it may, the majority of the portraits which appear, are little better than caricatures of the individuals depicted, and reflect very little credit on those who make them, whoever they may be. Unfortunately, or fortunately, our law courts are too badly lighted to permit of the use of detective cameras, or undoubtedly they would, long ere this, have been pressed into service for obtaining surreptitious portraits of those who are often reluctantly compelled to appear in sensational cases.

Photographing Scenes of Accidents.—We have frequently alluded to the great service photography might render in the cases of accidents or catastrophes, if the scene were photographed before anything was disturbed. By this means, often, a more correct idea could be formed as to the cause than any amount of verbal evidence. In the case of the late explosion at Dublin Castle, we are given to understand, as soon as the excitement, consequent upon it, had somewhat subsided, the authorities had the scene photographed.

Pastel Portraits Once More.—*Trade, Finance, and Recreation*, which is treating its readers to a series of articles on "Roads to Easy Fortune," deals, last week, pretty roughly with the "Pastel Portrait Business." Although this affair, or affairs, has been exposed time after time, and in spite of legal proceedings, it appears, according to our contemporary, to be still flourishing, and recommending its "No. 614" as the most suitable frame for the two guinea free portrait. Something for nothing will always be a good bait for the gullible.

Patents in 1891.—The number of patents applied for during the year just ended was over fifteen hundred more than in the year before, which was much in excess of any previous one. Last year the actual number was twenty-two thousand eight hundred and seventy-two. As yet the numbers are not classified, but, to judge from the lists that have appeared weekly in our columns, the applications in connexion with photography will show a considerable increase over all previous years. What a marked difference there is in the number of applications for photographic patents now and in former times! Going back, say, twenty years—that is, 1871—we find the total number of patents, directly and indirectly connected with photography applied for, was only twelve for the whole year, a few more than are sometimes applied for in a single week now. Are photographic inventors more mercenary now than they were formerly? It would certainly seem so. Now, any little improvement or modification appears to be made the subject of patents. In former days it used to be freely given away, and this was the case with all the most valuable inventions in connexion with the art.

Bromides for Platinotypes.—A provincial photographer says he is told that it is very general with London houses, when platinotypes are ordered, to supply bromide prints instead when the light is bad for printing. He adds that one of his customers showed him some portraits sent out as platinotypes that he feels convinced were bromide prints, though they were very good. The object of our correspondent's letter was to inquire if, in such cases, the Trade Marks Act would not apply? That some photographers may sometimes supply bromide for platinum prints is quite possible, but that the practice is at all general we do not for a moment believe. It is a pity that the writer did not satisfy himself as to the genuineness or otherwise of the prints he suspected. This he could have conclusively done by simply immersing one of them in a solution of bichloride of mercury, which would quickly bleach a silver image, while it would have no effect on a platinum one. Undoubtedly the Trade Marks Act is infringed, and a penalty incurred, if silver prints are sold for platinotypes.

Purity of Water.—As the purity of water is always a subject of importance to photographers, we draw the attention of our readers to an address delivered by Professor Leeds before the Chamber of Commerce of Rochester, New York, which is printed at length in the *Chemical News* for January 1. One leading point in it we may here allude to. We have heard the presence of bacteria in water held accountable for many sins of omission and commission on the part of the operator, from blisters and bad toning in prints to fogginess in dry plates—which latter, by the bye, might easily be caused by bacteria setting up decomposition in the emulsion before washing. The point, however, we wish to draw attention to in Professor Leeds' paper is his observation, which has thoroughly been reduced to practice, that a water which is opalescent or unclear-looking after filtration may be made perfectly clear and bright by the addition, before filtering, of so small a quantity of alum as one quarter of a grain to the gallon. This has a marvellous effect in producing a bright and limpid water, and it assists in arresting almost all the microbes present.

A PLEA FOR FAIR PRICES.

For the past ten years the prices charged by photographers for their work have had a downward tendency, and where a guinea a dozen was at one time easily obtained for vignette *cartes* or Berlin heads, half that price is about the present average. It seems to me that the profession have been themselves to blame for this wholesale lowering of prices, and there is little doubt that they are now suffering for it. A few years back the proprietor of a moderately quiet business, taking some twenty-five sitters a week, could make a comfortable living for himself and family: with the reduction of prices he undoubtedly thought there would be an increased business, and a proportionately increased income, but he now finds that, with about the same number of sitters per diem as he then had per week, his income, after deducting working expenses, is less than it was before! The main cause of this lies in the fact that, in order to get through the increased work, he has not only had to take larger premises, but to employ a much larger staff. Then, again, competition has become much keener than it was, and many a town which then only contained one photographic studio has now several to support. I could name many a town as proofs, but let two suffice. One in the eastern counties, of between 20,000 and 30,000 inhabitants, had, at the time I speak of, three photographers therein plying their calling; now it contains no less than ten or eleven. Another, in the western district, had two where now six are to be found. At fair prices, each of these studios would bring in a respectable income to its proprietors; but, what with the cutting down of prices and the amateur competition (save the mark!), they can only barely exist, and some must, in the end, go to the wall. The sufferers will, in most cases, be those who try to run between the extremes of high and low prices. The best class of sitters will continue to patronise those whose charges are the highest; while the middle and lower classes will go in for the cheapest goods they can obtain, leaving very few patrons indeed for the medium-price man.

There is one branch of the profession which I had fondly hoped would maintain its character and continue fairly remunerative. The branch to which I refer includes enlargements and coloured work; but even there the price-cutter is at work, and I was disgusted only a few days since at seeing a twelve-ten opal nicely worked in monochrome and tastefully framed, exhibited as "*Our twenty-five shilling enlargement.*" This must leave a very small margin of profit indeed, and is decidedly a step in the wrong direction. Those sitters who require, or whom we can make believe they require, enlargements will pay two guineas or even three just as readily as twenty-five shillings, and I fail to see why we should rob not only ourselves of a little extra profit, but also cut down the remuneration of the enlarger, the artist, and the framemaker for no purpose whatever, unless it is to cause other photographers to do the same.

Possibly another cause for the reduction in price of enlargements is to be found in the fact that some of the trade enlargers have been and are doing enlargements for amateurs and the general public at the same prices as if for the profession; this is manifestly unfair to the photographers who have supported them hitherto, and demands strong concerted action on their part. Perhaps the best thing would be to "boycott" any firm found working for the public at professional prices; if they like to supply the public at fair prices, as charged by the photographers, it would merely be fair competition, but undersselling cannot be tolerated at any price. I have an idea that, if several professional photographers were to form a syndicate for the purpose of enlarging and working up enlargements, it would be found a paying concern. They themselves would not only get their work well done at moderate prices, but would share any profits among themselves, added to which many other members of the profession, not necessarily members of the syndicate, would send their work to them to be done and pay a fair rate. Perhaps this hint may bear fruit in the near future.

C. Brangwin Barnes.

CONTINENTAL NOTES AND NEWS.

Testing for Hypo.—"If you want to know," says M. E. Caputo, of Naples, "whether the wash water of your negatives or prints still contains hypo or not, drop a little of 'this rose-coloured liquid' into the water. If the water is coloured thereby, no hypo is present; if, on the other hand, the water goes colourless, continue the washing." Very good; but what *is* the "rose-coloured liquid, Monsieur—or rather Signor—Caputo, please?

Incandescent Platinum Light.—In the *Comptes Rendus*, M. Paquelin describes an incandescent platinum light of his own devising. A strip of platinum coiled on itself is placed in a platinum bowl with a hollow stem. A mixture of air and hydrogen carbon vapour is then introduced under pressure. The mixture is set alight, the flame disappears, and the strip of platinum incandesces, the intensity being in the ratio of the pressure. With moderate pressure, the light is said to be comparable to that of an electric lamp.

Dinner to M. Jannsen.—A body termed the "Scientia," apparently a kind of Parisian science club of a somewhat exclusive character, "dined" Mr. Jannsen, the astronomer, on Christmas Eve, in recognition of his eminence and achievements as a man of science. Some of his predecessors in the honour are Pasteur, Renan, de Quatrefages, Jules Simon, Chevreul, Leon Say, de Lesseps, Eiffel, &c. M. Gaston Tissandier presided. "Giving a man a dinner" when he has done, or is going to do, something has hitherto been looked upon as a purely British custom. Apparently it is not.

French Photographic Papers.—During the year 1891 French photographic papers have increased to a large extent upon preceding years, some fourteen publications devoted to photography being now published, while others are in contemplation. If all are read, says our *confrère* of the *Moniteur*, so much the better, and we echo the sentiment. "Press buttons," however, according to the same authority, do not read photographic papers; with them photography is purely automatic throughout. They require to read nothing except the "directions on the box." Such as these could not understand what was printed in a photographic paper.

A Ladies' Photographic Club.—There is talk of the formation in London of a photographic club to which ladies are to be admitted. The club will comprise reception-rooms, laboratories, a library, and will be furnished with the utmost possible comfort. Besides ladies residing in London, the club will admit country members, who would be desirous of finding a temporary photographic home when passing through the metropolis. They say other people always know more about you than you do yourself, and this, we think, is a case in point. The information comes to us all the way from Vienna. We have not heard anything about it in London. It reads too rich to be true.

French Patents.—According to an account of the photographic patents taken out in France since the introduction of photography, it appears that the first patent applied for was in 1839, for a camera. In 1840 there were two patents taken out. From 1844 to 1860, the number of patents for apparatus, on account of more liberal laws, increased very largely, the latter year recording forty-one. In 1871 (the great war year) the number dropped to four. In 1890 it ascended to seventy-two. The chemical patents were, of course, much smaller, and the total number, looked at from every point of view, compares most unfavourably with that of British patents. Perfidious Albion simply "loses" in Belle France, in this respect at any rate.

Relics of Primeval Photography.—Happy Société Française de Photographie! At the meeting on December 4 last, M. Davanne presented a veritable camera negative obtained by Nicéphore Niepce, "the inventor of photography," accompanied by a letter written by Niepce himself. At the same meeting M. Forest also presented a Daguerreotype view of the village of Bry-sur-Marne, taken by Daguerre, and duly authenticated. In years to come these relics will be of inestimable value, and, the greater number of them that come into the hands of public bodies like the Société Française, the greater their chance of ultimate preservation. Private individuals are, for obvious reasons, the worst custodians of these treasures.

Magic Photographs.—Metaphorically speaking, we rub our eyes at beholding in one of our Parisian contemporaries a full, true, and particular account of how to make magic photographs. Several of its readers, it seems, had asked how these pictures were done, and the journal quotes the method from *Les Récréations Scientifiques* of MM. Bergeret et Drouin. Who *are* MM. Bergeret et Drouin that

they should be held up to us as authorities on this momentous point? Then the journal in question goes on to gravely tell the world how to bleach prints with mercuric chloride, and blacken them with sulphite or hyposulphite of soda, and winds up with the information that such is the "secret" of magic photographs. Shade of Scott Archer—thy "secret" in the keeping of MM. Bergeret et Drouin! What next?

Eikonogen-Pyro Development.—The *Deutsche Photographische Zeitung* recommends, where any difficulty is experienced in getting sufficient density with an eikonogen developer, to add a solution of pyro to the solution, and proceeds to give formulæ for the purpose. If there is one property of the photographic negative more than any other which it is desirable to have completely under control, it is that of density. Without it the finest detail, the most delicate half-tones, and the completest absence of veil from lights and shadows are of secondary importance. There is a touch of the irony of fate in the necessity experienced or even suggested that pyro's rival, eikonogen, should sometimes require its assistance to finish its work for it. Pyro still holds the field as an all-round developing agent, from which no one of its homologues or congeners will ever probably dislodge it.

A NEW TELESCOPIC PHOTOGRAPHIC LENS.

(JOURNAL OF THE CAMERA CLUB.)

THE object I have in view, in the lens-construction to which I invite your attention to-night, has been to produce large primary images, of sufficient brilliancy to be of practical value in rapid photography; there are also other advantages, to which I shall refer later on.

Hitherto only two methods of accomplishing the end in view have been employed to produce large images: first, the employment of very long-focus positive ordinary lenses; and, second, the production of a primary image by one positive lens, and placing a secondary magnifier, or second positive lens, behind the plane of the primary image, which enlarges it more or less, according to its focal length, and its adjustment between the positions of the planes of the primary image and that of the focussing screen, as in the photo-heliograph, &c.

The first of the older methods has been seldom employed, except in astronomical photography, on account of its unwieldy dimensions, and the second method referred to is practically useless for ordinary photographic work, on account of the great loss of light involved, rendering the length of time necessary for proper exposures so great as to cause it to be almost prohibitive, except for inanimate objects.

The new lens, as you are already aware, is composed of only two elements, and the image given by it is primary and inverted. By the fact of the image being primary and inverted, it looks, at first sight, anomalous that for equal extensions of camera, the image given by the new lens is several times larger than that given by an ordinary lens of hitherto known construction.

In comparing two lenses, no matter of what form of construction (when focussed upon a distant object), if the size of the image given by one is *n* times that given by the other, you are aware that the focus of the one is *n* times that of the other, provided, as before stated, the images compared are direct, primary, and inverted.

The focal length of a lens is measured, for practical purposes, by the distance between one of the principal planes passing through one of the nodal points of the lens towards the principal focal plane (where the image is received) and that plane.

In most lenses in existence the position of the principal plane referred to can be marked upon the lens-mount and has already been suggested, first, I believe, by Mr. Warnerke, as an important addition to the measurement and description of lenses, as furnished by opticians. The most recent and important contribution, however, on this subject was recently furnished by Professor Silvanus Thompson in a very interesting paper, delivered on the 28th of November last, at the Society of Arts, and published in its Journal. In the case of the rapid rectilinear, for example, the nodal point referred to is not exactly at the diaphragm slot, but a little behind it; but in most lens constructions in use the nodal point is within the mounting of the instrument.

In some, however, by the accidents of construction, it is slightly behind the lens, as, for example, in certain forms of deep Meniscus, and in others it is slightly in front or beyond the mount, as in Petzval's orthoscopic. [In last week's BRITISH JOURNAL OF PHOTOGRAPHY this construction was referred to in a letter signed "E. Russell." I wish to call attention to the fact, that the object in introducing a negative element, in the orthoscopic lens referred was for the purpose of the cure of distortion, as its name signifies, although it was not perfectly accomplished, and the model point is thrown only slightly in front of the lens mount by the accident of construction. Mr. J. Traill Taylor has, I believe, already pointed out that this form of construction necessitated a slight enlargement of the image; but in his leading article in THE BRITISH JOURNAL OF PHOTOGRAPHY, of the 16th of October, describing my new lens, he says: "We have frequently dwelt on the advantages that would accrue from such a construction." The argument in Mr. Russell's letter, however, appears to be the good, chary, old one, "that there is nothing new under the sun."]

Now, the main object of this invention has been to *purposely* throw the nodal point, from which the focus is actually measured, to any distance I choose in front of the lens itself into space, thus attaining a large direct image, without the necessity of a bulky and long extension apparatus. This, then, is the principle of the construction, and I will now proceed to demonstrate the manner in which it is arrived at, as also point out the possibilities that the construction permits of qualities that have never existed in any former lens.

The anterior element is a positive lens, preferably of large aperture and short focus; the posterior lens is a negative element of some *fractional* portion of the focal length of the anterior positive lens (in Petzval's Orthoscopic it was more than twice the focus). Roughly, the shorter the focus of the posterior lens as compared with that of the anterior lens, the greater is the size (for a given extension of camera) of the enlarged primary image produced.

I have said that the anterior lens should be preferably of large aperture and short focus. It is self-evident, as, in ordinary constructions, the larger the aperture the greater will be the rapidity; and the reason of its being preferably of short focus lies in the fact that the absolute distance between the planes of its own focus for parallel rays on the one hand, and a near object on the other, is, of course, less with a short-focus lens than with a lens of long focus.

A similarity between this construction and the Galilean Telescope was referred to lately in a French paper, the *Photo Gazette*, by M. Wallon. This, as I pointed out to M. Wallon, of course, is not so absolutely, in that the rays emerging from the Galilean Telescope are divergent, and not convergent; but, by a correct adjustment of the two elements composing the new lens, it *can* be employed as a Galilean Telescope, as I described to Mr. Traill Taylor in the latter part of September.

Referring to the figure, if the negative lens B be placed at proper distances from the positive lens A, the rays can be made to emerge parallel, divergent, or convergent.

For the purpose of forming an image for any given position of the focussing screen, they must be made convergent, producing a direct primary inverted image.

It is immaterial what position may be chosen for the plane upon which the image is to be received; it may be either in close proximity to the posterior lens, or removed to any distance whatever further away; but, in order to focus, it is essential that a correct distance be given between the two elements of the lens itself; in other words, a correct adjustment of their separation, focussing always being most easily and sometimes necessarily accomplished in this manner (Fig. 1). For example, supposing the lens were focussed upon a very distant object—say, the sun—with the focussing screen set at a given distance, it would be impossible by any adjustment whatever of the focussing screen to find a plane where the instrument would come to focus for very near objects (Fig. 2).

Near objects with the lenses in their former adjusted or fixed position would send the rays from such objects, after passing through the entire lens, divergent and not convergent.

On the other hand, if the separation were adjusted between the two elements for a near object, and it was then pointed towards a distant object, it would be found equally impossible to find any position for the focussing screen, in which the focus could be observed, except, as before stated, by an alteration between the separation of the component element of the lens itself.

It is evident that, the longer the focus of the positive element in the construction, the greater would have to be the separation between the two elements for near or distant planes.

In this construction there is, then, no limit to the size of the image that can be obtained, a slight adjustment in the separation of the two elements producing the correct focus on the screen, be it near or distant from the lens itself; but it must be borne in mind that the greater the separation between the plane of the focussing screen and the lens, the less is the rapidity that can be attained (Fig. 1.)

I will now call your attention to the question of rapidity. Sup-

posing the screen be placed at a distance of ten inches from an ordinary lens, and a distant object focussed, say the lens has a focus for parallel rays of twelve inches, if the new lens be made to take its place, and the same object be focussed, it will be found that the image produced is five times larger with the new lens than with the ordinary one, you know then that you are practically, and to all intents and purposes, employing a lens of sixty inches focus!

The question naturally asked is, What will be the rapidity? The answer is, that you have to consider the front lens placed at a distance of sixty inches from the focussing screen; in other words, the nodal point is thrown forward outside the lens to a distance of sixty inches from the focussing screen (Fig. 3).

It is evident to you, then, that too much stress cannot be laid upon the desirability of large aperture for the anterior positive lens.

In the case cited, supposing the lens to be of three inches aperture, you would then be working at an intensity of *f*-20.

difference with one and the same instrument in *the angle* included for moderate amplification or great amplification; but, of course, *more of the plate* is covered when it is removed further and further away from the posterior lens.

Fig. 1

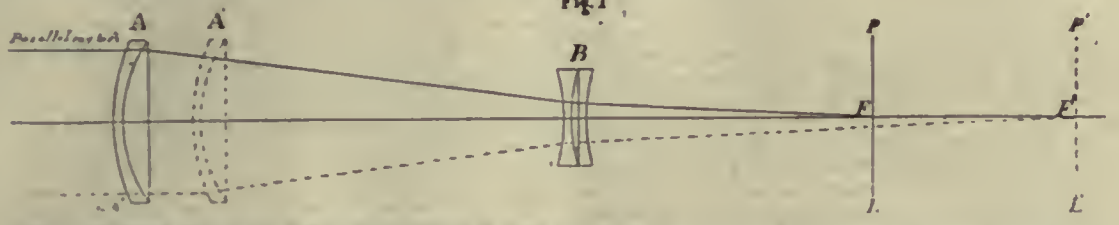


Fig. 1.—The upper black ray meets the lens A parallel to the axis, and, by a proper adjustment between A and B, comes to focus at F upon the plate F L. If F L be removed further from the lens B to take the position F' L', the lines A will have to be moved slightly nearer to B and take the position A'.
The lower dotted line represents a parallel ray falling upon A', which passes through the negative lens B, and coming to focus upon the new position of the plate F' L', at F'.

[The principle employed has a useful bearing on the subject of telescope construction, enabling very much higher powers to be employed on short telescopes.]

I shall feel indebted for any suggestions that may be made by you as to what may be advantageous for any particular applications you may have in view.

With regard to the hand camera, in which the back lens is, say, five inches from the plate, what focus would you like such a construction to represent?

Then, again, for covering larger plates, what is the minimum extension and minimum angle that will be required?

Again, for the sportsman or naturalist, what is about the most convenient length and dimension of plate of box camera to carry?

It will doubtless be interesting to many to know that the applications of this lens to astronomical photography are easily accomplished, and, moreover, valuable, I think.

The negative of the moon that is before you was taken with the first rough lens I completed, with an extension of only twenty-eight inches. I look upon it more as an example of possibilities in size and rapidity of action than definition (that, as you see, I have subsequently attained), although as it is, it has been, I am pleased to say, favourably criticised by persons whose judgments I highly value.

In connexion with this instrument, I should like to point out that the optical finish required is necessarily that of the finest polish bestowed upon astronomical work, for, the greater the size of image chosen, the more are any slight optical defects exaggerated.

Fig. 2

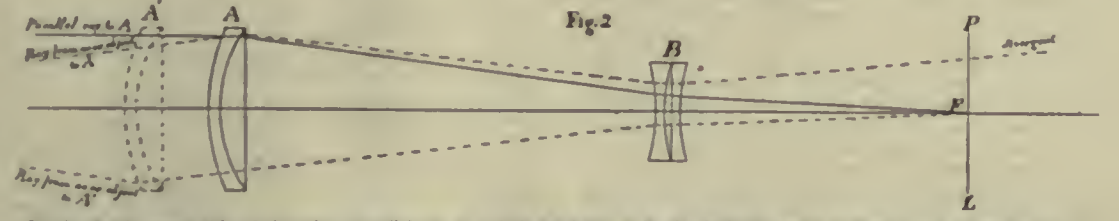

Fig. 2.—On the upper side of the axis a parallel ray to A finds its focus as in the dark line on the plate at F. If, however, some ray from a near object falls upon the lens A in the direction of the dotted line, after passing through the lens B, is found divergent, and no positive focus is obtainable.
In the lower half of the figure, however, A is presumed to take a proper position in A' when the ray from the near object passing through A' and also through the negative lens B finds its focus upon the plate in the fixed position chosen, at F.

In employing this lens, conditions of light will naturally suggest whether it be advisable to employ moderate amplification by having the focussing screen near the lens, the nodal point being thrown moderately forward, or whether the conditions are such as to have a considerable distance between the lens and the focussing screen, and thus throw the nodal point, by the focal adjustment, a long way in front of the lens.

I repeat again that the difference between this and former constructions lies in the fact that any focus that one may choose to employ can be obtained from the minimum (dependent upon the ratio between the foci of the elements), when the plate is close to the posterior lens, up to a maximum, controlled solely by the length of the camera extension possible.

As in the case of the telescope, the greater the magnification required, the less becomes the angle included, and there is very little

Fig. 3

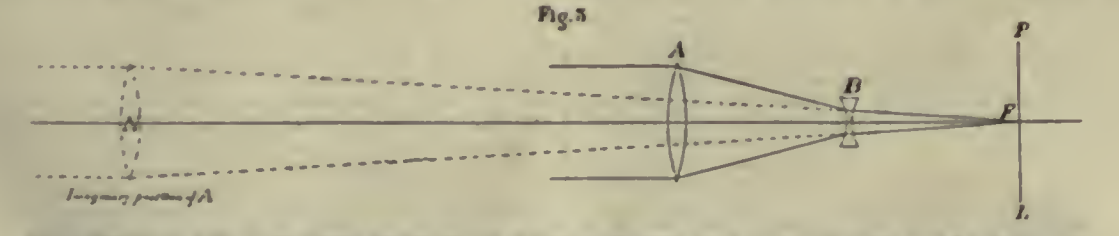

Fig. 3.—Represents a beam of rays passing through the two component elements, A and B coming to focus upon the plate F L. To estimate the rapidity, it is necessary to consider the full aperture placed at the principal focal plane passing through the nodal point at B, A is thus made to take up an imaginary position.
The position of the nodal changes for different positions of the plate F L.

It is possible that the application of short-focus concave lenses, such as myoptic spectacle eyes, in connection with rapid portrait lenses (that in themselves will form the positive elements), will suggest itself to your minds.

Uncorrected lenses in this application will, I may say, cause disappointment; but I am engaged upon the construction of a properly corrected series of negative elements that may be employed in connexion with rapid short-focus portrait lenses, whose construction and correction I am responsible for, so that many who have practically placed their very rapid short-focus portrait lenses upon the shelf will now find a new and interesting application for them.

In conclusion, I may say that I have endeavoured, in this new lens, to reduce the bulk, weight, and loss of light to a minimum; and, while thanking you, gentlemen, for the very kind hearing you have accorded me, I hope that you yourselves may perchance find the instrument as interesting in its various applications as its conception and construction have been to me. THOMAS R. DALLMEYER.

Previous to reading his paper Mr. Dallmeyer exhibited two sets of negatives of distant objects, taken from one and the same point of view with a 10×8 rapid rectilinear lens of thirteen inches focus, and the new lens, with the same extension of camera. One set shown represented a church a quarter of a mile distant, and another set representing the Alexandra Palace Station, the distance in this case being estimated at somewhat over a mile. In both instances the images produced by the new lens were five times (linear) greater than the correspouding images produced by the rapid rectilinear lens. Other negatives were also shown; the magnification and fine definition with the new lens was the subject of much comment and admiration by the members present.

To practically illustrate the properties of the instrument, Mr. Dallmeyer had placed two cameras at a distance of about twenty feet from a small oil lamp, on which were fixed respectively a fifteen-inch "long-focus landscape lens," and the new "tele-photographic lens." It was clearly demonstrated that with equal extensions of camera, the image of the flame on the ground glass was five times greater in the case of the new lens than in that of the ordinary "long-focus" lens; with a greater extension of camera for the new lens, the image was very much larger.

In the course of the paper, lantern slides, representing sheep and horses, taken from 250 yards to a quarter of a mile off, were also shown. In the case of the sheep, comparison slides, taken from the same point of view, with a 15×12 rapid rectilinear of twenty inches focus, and the new lens, were shown, the effect of comparison being very striking. These transparencies represented instantaneous work in dull weather, but were very favourably commented on by the audience. A transparency from a negative of the October full moon was also much admired.

Discussion.

Mr. Traill Taylor said it was a matter for congratulation that one of their members was giving them a lens which, in his (the speaker's) opinion, would be useful in several directions, and had long been a desideratum. He himself had many years since adapted a barrel of the ordinary twelve-lens Voigtlander opera-glass to the camera, and had thus obtained greatly enlarged views, but his fault with it was that its covering power was limited; the image was sharp enough in the centre, but the sharpness was confined to only a few inches around the centre. He had prepared a paper *On Making Enlarged Views by One Operation*, intended to be read at the Bradford meeting of the British Association in 1873, but, instead of devoting it to that purpose, he slightly altered it, and gave it as an editorial article in THE BRITISH JOURNAL OF PHOTOGRAPHY in that same year and month (September 19, 1873), where it would be found. He had not been able to see what construction of eyepiece or negative lens Mr. Dallmeyer employed, but he had no doubt that it was efficient, would answer its purpose well, and do all that was claimed for it.

Dr. G. L. Johnson wished to refer to a point not directly bearing on the lens now described by Mr. Dallmeyer. He had been using a lens working at *f*-4, not a portrait lens, for copying equal size, and found at some points it was absolutely impossible to get a sharp focus. The camera might be moved back half an inch, and then it was easy to obtain focus; another half an inch, and again no focus is obtainable, and so on alternately. He wished to obtain an explanation of this.

Mr. A. Hayman did not see why the new form of objective should not be used with the binocular telescope. He also referred to its adaptation to microscopic objectives of high powers, and inquired as to the origin of Mr. Dallmeyer's experiments.

Dr. Fison asked what was the exposure given for the moon photograph shown? He had not seen anything so good not taken with clockwork movement.

In reply, Mr. Dallmeyer thanked the members who had spoken for their kind expressions with regard to the invention. Mr. Traill Taylor had spoken in very complimentary terms of the achievement, but at the same time seemed to infer that the idea was of his own suggestion. This was very surprising to him, in that when the instrument was first shown to Mr. Traill Taylor, on the 24th of September, he had expressed himself as *astonished*, and had said he had no notion as to the manner in which it was accomplished. He had invited Mr. Traill Taylor, in a friendly way, to see the invention at his office, in the latter part of September, and in this sense had asked Mr. Taylor to furnish him, from his long experience, with any methods that he knew of that would accomplish the end in view. Mr. Traill Taylor had not referred to what Mr. Dallmeyer now understood was put forward as a suggestion originated by Mr. Traill Taylor. In reply to Dr. Lindsay Johnson, Mr. Dallmeyer said that the experiment as described appeared to be anomalous, for at first sight it seemed suggestive that there was some curious property at the positions of the planes for equal magnification, now known as the "symmetrical" planes (happily christened by Dr. Silvanus Thompson). There was, however, in reality no such property, and the only suggestion Mr. Dallmeyer could make for the lack of defining power for near objects was that, if a lens were perfectly free from spherical aberration for parallel rays, there would be a tendency to show negative spherical aberration for near objects, and this would render focussing more difficult. Mr. Dallmeyer would be very pleased to try and elucidate the matter, and examine the lens with Dr. Lindsay Johnson. Mr. Dallmeyer thanked Mr. Hayman for his suggestions. With regard to the binocular telescope, the suggestion was useful and valuable, but at present the great difficulty one had to contend with in the ordinary binocular was the smallness of the field when high powers were employed, so that, although it was possible, by adding a second negative element removed to a proper position from the first, to attain very much higher power, the field would thereby become very small. Mr. Dallmeyer had already considered the adaptation of the principle involved to the microscope, and, although the thoughtful suggestion Mr. Hayman had made *could* be employed, he must remember that by its introduction the magnifying power also of the objective would be reduced by necessarily lengthening its focus. Mr. Hayman had asked how the construction of the instrument had been brought about. Mr. Dallmeyer was glad of the opportunity of referring to this. In his summer holiday, spent with his friend Dr. Emerson, whose attention was now partly devoted to the study of natural history, that gentleman had asked Mr. Dallmeyer to try and fix up for him a large object-glass of some six feet focus, corrected for photographic purposes, mounted in something very light and collapsible, such as in bamboo, carrying the lens at one end and the sensitive plate at the other, in order to obtain large images of distant objects. As a matter of fact, Mr. Dallmeyer had tried, in the first instance, to get such bamboos, but had failed, and he thereupon devoted his attention to some means whereby a direct enlarged image could be obtained, which resulted in the construction he had presented to them that evening. Mr. Dallmeyer was very gratified with Dr. Fison's criticism of the photographic transparency of the moon. The length of exposure was barely one second, in fact, cap "off and on" simply.

[Had there been a short-hand reporter at the meeting to take down what was really said, it would have been seen that Mr. Taylor promptly denied having been asked by Mr. Dallmeyer whether he knew of any means by which such a telescopic effect as that shown him could be produced. Mr. Dallmeyer's memory is slightly at fault as to our having expressed "astonishment" at such effects. It was quite another thing that elicited the expression of this feeling—viz., the exhibition to us of a reflecting or mirror objective for a telescope to be employed as a comet-searcher, and our astonishment arose from its enormous angular aperture, for the focus was very short, and, when the means for correcting the spherical aberration of the mirror were explained, we expressed our admiration, which has not suffered any diminution since, of the ingenuity of the clever optician.

As regards the teleo-photo lens, had Mr. Dallmeyer asked us the question above narrated, we *should* have been a good deal astonished, for we thought that every optician knew that both the astronomical and the Galilean, nay, even the ordinary terrestrial, telescope had long been employed in the production of photographic pictures. Mr. Dallmeyer had not at this time afforded us an opportunity of seeing his new objective, or of learning anything concerning its construction, although we saw the image of his lamp-flame on the ground glass, and expressed our gratification at the prospect of the commercial introduction of a lens which would place a new power in the hands of photographers.

It was only at the Camera Club meeting that we learned for the first time the construction of the negative lens of the combination. But that this application of the Galilean or opera-glass telescope was, or ought to have been well known, at any rate to the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY, is a fair assumption, seeing that in the JOURNAL and its ALMANAC it has been described no fewer than three times, and not as a crude suggestion, but as an accomplished fact, and never, in any sense, as an original suggestion of our own. Now for the proof. In this JOURNAL of September 19, 1873, and in course of an article entitled "Enlarged Views by One Operation," after speaking of lenses made expressly for taking telescopic photographs in military and naval engineering, we say:—

"As lenses of very long focus necessitate the use of cameras of great

length, the same object—that is, the production of an enlarged direct view—may be obtained (certainly on a plate of small size) by the use of a combination of lenses, the optical centre of which shall be at a considerable distance outside the lens. Of this kind the common opera-glass furnishes an example. An opera or field-glass, if used as a camera lens, produces an enlarged image of objects in nature. We do not here refer to the use of the large or 'object glass' of the instrument, but the combination of object-glass and eye-glass as used for looking through. An objective of this kind will produce an image having a considerable degree of amplification, this depending upon the power of the instrument. Although there is a fair degree of sharpness in the centre of the picture, it unfortunately does not extend to any distance from the centre. This, however, could be remedied, within certain limits, by the adoption of an eyepiece possessing a similar form to that of the negative combination of the old orthoscopic combination. We have an old opera-glass which possesses in a remarkable degree the property of producing a large image with sharpness. Its peculiarity of construction consists in each barrel containing three lenses, each composed of three elements cemented together. The object-glass is apparently a plano-convex, but is in reality a double convex of very unequal external curves; the centre lens is biconcave, and the eyepiece plano-concave, each of these being achromatic in itself. The magnifying power is very great, and, when used as a camera lens, it gives quite a telescopic image."

Again, in the JOURNAL for February 18, 1870, in an article headed *Direct Enlargements*, after combating an impracticable idea, suggested by the chairman of the then existing South London Society, relative to enlarging an aerial image, we spoke of the "old familiar fact" that telescopes with their eyepieces could be employed in the production of telescopic photographs, and described the application of one of the Galilean class (an opera-glass) to this purpose.

Once more: In our ALMANAC for 1877, at page 104, under the heading *A Novel Enlarging Lens*, we say:—

"It may not be generally known that, by means of an opera-glass used as a camera objective, a greatly enlarged image of any view to which it is presented may be obtained. Owing to the shortness of the tube, and to the optical principles involved in the formation of a large image by means of an objective when used in conjunction with a concave eyepiece, this form offers advantages in the production of a directly magnified image not possessed by the ordinary telescope. . . . . This form of 'tube,' when used as an objective for the camera, produced images of great sharpness in the axis, the sharpness being more extended than I have seen it with any other form. By means of this instrument I obtained an excellent and sharp photograph of the sun three inches in diameter."

From the foregoing it will be seen that the principle of applying the Galilean telescope to photography is not a novelty. We repeat what we have already said, that we are much pleased to find that Mr. Dallmeyer has introduced the lens commercially, and this quite apart from what has been previously written concerning the possibilities of such lenses. In introducing new lenses, or lenses believed to be new, however, opticians must take the fortune of war, and they are certainly open to reproach if they do not seek ordinary means for ascertaining what has been achieved or attempted in former times.

Does Mr. Dallmeyer see any possibility of escape from this inconvenient reproach?—ED.]

MR. J. PATTISON GIBSON AT THE CAMERA CLUB.

THE sixty landscape pictures by which Mr. J. Pattison Gibson is represented at the eighth One-man Exhibition of the Camera Club that opened on Tuesday last, January 5, unquestionably take equal rank, judged by any system of comparison, with the best of the collections which have hitherto been placed on view there.

Mr. Gibson is a loving student of nature in her comeliest moods, for his pictures are mostly transcripts of northern wayside, river, and woodland scenes, though, by way of relief, or perhaps contrast, to this vein of repose, he now and then directs his camera towards a snow scene, a mouldering abbey, or a grim, rock-perched castle. Those of us who may have been satisfied to believe, and rash enough to say, that the Tyne was essentially, if not entirely, a "coaly river," will be surprised and delighted at finding that it is occasionally not inferior in beauty to the Thames at Maidenhead. Of the smaller works, *The Lonely Moor*, *The Beautiful River*, *The Banks of Tyne*, and *The Ford*, are, perhaps, the most artistically chosen, and perfectly exposed pictures in the collection.

Mr. Gibson's small work is, indeed, on the whole, to be preferred, both technically and pictorially, to his larger frames, the latter, however, being never larger than 12 × 10. Of these, *The Thaw* is not only a very truthful rendering of a difficult effect, but succeeds in nothing so much as conveying the sensation of departing chilliness to the mind of the spectator. In *An Autumn Haze*, on the other hand, the haze is, as it were, too clearly and obviously localised to the centre of the picture and *Twilight*, a most ambitious attempt, from the same species of defect, only just fails of real masterfulness. Mr. Gibson's haze effects, in fact, as well as a somewhat prominent idiosyncrasy in shading off distances, to secure the best effects of depth and separation, are not so happy as one could wish.

To our mind, however, Mr. Gibson scores an unqualified triumph in *Weary*, a fine theme, most ably and dramatically handled. In the foreground of the picture reclines a tired woman, while the road stretches away for miles, forbiddingly hard and cruel, across an undulating country. It is late afternoon, and the sun is well on the decline. On all hands, it must be allowed that in this picture Mr. Gibson shines poetically, pictorially, and technically. It is unquestionably the finest in the collection.

Mr. Gibson's prints are seemingly chiefly done in platinum or bromide, and the key of most of his tones is that of thoughtfully subdued warmth. His clouds are always cleverly chosen and carefully introduced, and he is laudably sparing in the employment of figures. This very sparingness, however, is the secret of his success in a branch of his art in which few photographers excel. Shall we add, too, that we do not find in any of his pictures a semblance of that unfortunate misapprehension of the functions of a photographic objective which has recently prevailed among many otherwise clever photographers?

Alike to the student or beginner in landscape photography, and that large section of the public to whom the high level of artistic excellence reached by modern photographers is as yet but a partly opened book, Mr. Pattison Gibson's admirable collection offers a capital educational opportunity for the most searching inspection and analysis. Modern landscape photography and one of its acknowledged masters are here seen at their best.

THE ACIDIFIED "HYPO" BATH.

["AMERICAN ANNUAL OF PHOTOGRAPHY."]

FOR so many years photographers have been warned against the danger of acid in their "hypo" bath, that the mention, at no distant date, of an "acid fixing bath" would have excited derision only. In many ways this dread of acid is a desirable fright to cultivate, for acid hypo was one of the causes of the fading in old silver prints on paper, and so many artists' work by "rule of thumb" only that, unless the fear of acid in their "fixing solution" were constantly held before their eyes, there would be danger of an era of economical experimenting and fading.

A bath of hypo rendered acid by mere addition of acid, such as tartaric, citric, &c., it is not advisable to use. Several unstable sulphur acids result from the mixture, and the inevitable result would be deposition of sulphur and salts of silver within the film—be it of albumen on paper or gelatine upon glass. It has, however, been shown that an acid sulphite may be added to the hypo without any apparent reaction whatever taking place, and this is the form in which the fixing bath is made acid when required.

At this stage some of my readers may ask, "What does all this tend to—why make the bath acid?" The answer is (first letting it be understood that only the hypo bath for negatives is now in question) that, when the bath is rendered acid, it keeps in very good condition much longer than when made in the ordinary way, and it prevents to a great extent the yellowing of the negatives that is brought about when they are fixed day after day in an old bath. Negatives fixed in an acid bath have a crisper, clearer appearance, are usually free from yellowness, and, in consequence, "print much quicker." It may be safely said that no one who has given the method a fair trial will go back to the old plan.

But it will be well to point out certain governing conditions in the use of fixing baths generally. A given weight of hypo can only take up a certain amount of bromide of silver, and, if the bath approach saturation point, the result of using it may be the production of insoluble salts of silver within the film, which eventually decompose and lead to the destruction of the quality of the negative, or, perhaps, cause a so-called fading. Hence it should be a rule of working always to use a large overplus of the salt to be on the safe side as regards permanency.

Then, as to the yellowing, the real cause of which is not by any means well understood: When there is no sulphite in the developer, the discolouration always occurs through the products of decomposition of pyrogallol staining the film; with sulphite in the developer this is minimised to a greater or less extent, but not always prevented entirely.

Singularly enough, another cause (for years well known to me and very likely to others) had not been publicly mentioned till Mr. Cowan, at the London and Provincial Photographic Association, pointed out that the employment of the hypo after being previously used for the fixing would cause the yellowing. This is perfectly correct, and it is strange

that no one before called attention to the fact. I would, however, add here that very much depends upon the character of the film as to the extent it will discolour. A thin film will, in ordinary hypo, remain uncoloured when a thick one would be a dark yellow. The same will be observed when using acid hypo: If working with one kind of plate the bath may be used for days, while another kind will begin to discolour after comparative brief use. It is such unnoticed variations of conditions as these that cause the discordant verdict we so often peruse when novel modes of treatment are written about.

In conclusion, I may say I have, since I first used acid in the "hypo" bath, developed it with many hundredweights of hypo without any evil results, and with great benefit to the appearance of my negatives.

It is said that the best plan is to use the bisulphite of soda of the shops. But this is not so readily obtained as ordinary sulphite, and it does not keep well. Hence, I use, for the sake of uniformity, recrystallised neutral sulphite, and I acidify it with sulphuric acid, as being cheaper and just as good as any of the crystallised acids, tartaric, &c., usually recommended. Here is the formula:—

Sulphite of soda	2 pounds.
Strong sulphuric acid	2 ounces.
Water	1 gallon.

Mix the acid with a pint of the water; dissolve the sulphite in the remainder: add the two liquids together.

Of the solution so made, add half a pint to each pound weight of hypo when dissolved to the required strength.

G. Watmough Webster, F.C.S.

THE PHOTOGRAPHIC SOCIETY'S LECTURES.

Mr. Thomas Bolas on the Application of Photography to the Industrial Arts.

On Tuesday evening last the first of the three public lectures arranged for by the Photographic Society of Great Britain was delivered by Mr. Thomas Bolas, F.C.S., the subject being "The Application of Photography to the Industrial Arts." Mr. H. Chapman Jones took the chair, and the attendance numbered between twenty and thirty.

Aristotle's and Kant's Definition of Art.

Mr. Bolas quoted Aristotle as saying that art is a system in which contemplation and contrivance precede production or making, Kant taking much the same view; and then went on to deal with the incentives to its cultivation, among these being the purchasing power of money, impulse, renown, and the necessities of life. As to the æsthetic sense, the beauty of a fleet of ships appealed to one man, and well-made machinery to another. Photography had been expressively, if loosely, called an "art-science." It was a popular phrase, and not a strict definition, such as Aristotle or Kant would use.

Scientific Principles.

Science was the knowledge of principles rather than knowledge of applications. Aristotle's view was that knowledge of conclusions was less important than knowledge of principles. He ridiculed mere scientific jargon, such as that it was more scientific to use grammes than grains. He once read something in which the student was exhorted to use ten per cent. solutions, and then told to make up solutions which were certainly not in ten per cent. proportions. A friend of his recently came into his laboratory, and adversely criticised the label on a bottle of gum. It should have been, his friend said, hydrate of gum. Unmeaning minuteness was often misapplied, and was a hindrance to progress. A little laboratory jargon was only useful in enabling a man to pose as a scientific man in some quarters. Definite untruths hindered progress. He would give an instance of this. An individual recently using a knife said the steel was as soft as butter, and condemned it, but said he found a softer specimen to be as hard as a diamond. The scientific aim had led to good results, when the efforts of the noisy commercialist had not. The negative gelatine process was an illustration of the influence of the scientific aim.

The Scientific aim in the Gelatine Process.

Prior to 1861, suggestions for the employment of gelatine were vague and attracted little attention. The subject was then brought forward by Captain Dixon, who was a co-worker with Hardwich and Sutton. Dixon's experiment culminated in the taking out of a patent for collodion emulsion; Gaudin, working about this time, stated his preference for gelatine over collodion for the purpose. At p. 157, of Sutton's "Notes," for June, 1861, Gaudin said gelatine which could be mixed in nitrate of silver, was most convenient for photogenes. His emulsion was made with separately washed silver iodide and excess of nitrate, and the directions were explicit enough for others to follow. The emulsion was adapted for negatives, and also for positives, by long exposure for printing out. He also pointed out, in the same memoir, how emulsions could be used for readily making developed prints on paper. An exposure of thirty seconds to candlelight and one in diffused light gave a latent image. Gaudin predicted the revolutionary effects of gelatine, but he was not a Commercialist. The matter rested there till 1868, when Mr. W. H. Harrison published a remarkable paper in The British Journal of Photography, on the "Philosophy of Dry Plates," which, from the scientific point of view, was a good elucidation of general principles. He prepared a gelatine bromide emulsion developable in an alkaline solution; Gaudin had developed in solution of tannin, which was non-alkaline. Mr. Harrison did not appear to have made any endeavour to put emulsions or plates on the market. He treated the matter from a scientific point of view, and there was no doubt that to him belonged the credit of having first prepared a gelatino-bromide plate, for alkaline development. He dealt fully with the scientific principles involved. In 1871 Sutton wrote a long letter in The British Journal of Photography dealing comprehensively with the whole question of emulsion making. Maddox followed next, and his process was analogous to Gaudin's. By this time, the way had been prepared for Burgess, Kennett, and others; but ten years elapsed before photographers realised the utility of the process. Gaudin, Harrison, and Sutton, showed the way for the commercialist. A knowledge of principles was the direct outcome of scientific aim, and scientific aim was at the bottom of scientific progress.

Facilities for Experimental Work.

In connexion with the suggested establishment of technological schools, facilities for experimental work should be afforded. At present this has to be done at a person's own expense, but it should be altered; he should not only have tools, but food and lodging. The modern principle of scarcely recognising work with the scientific aim was calculated to hinder the progress of technology. Public or national laboratories had been dealt with by Professor Oliver Lodge at the last meeting of the British Association. The commercialist at present had no means of knowing what had been done in the past, and great national waste had occurred through his attempting operations which experience had shown to be futile. The manufacturer should be able to get such information from a technical institute.

Discussion.

At the conclusion of the paper there was a brief discussion. Mr. William Bedford asked if Mr. Bolas would apply the same rule to the art side as to the scientific side in teaching, and the lecturer replied by quoting Kant and Bacon to show that the teaching of art was impossible, although certain manipulations might be taught which would enable a man to manifest his own individual impressions. The Chairman, from his experience as a teacher of so many years standing, found it difficult to persuade people that principles must be taught. They looked for an immediate application of them. Mr. E. Clifton looked in the near future to great assistance from the popular press, and thought journals of the *Tit-Bits* type useful in disseminating technical information. Mr. Bolas avowed himself a reader of *Tit-Bits*, and said he thought that these items of technical news should have a date and their source appended to them. Mr. W. Coles wanted to know how the food and clothing were to be provided, and how Mr. Bolas would distinguish between those entitled to facilities for experimental work and those who were not? The lecturer thought the questions outside the scope of his lecture. They must first recognise principles, and then find means. The means were a difficulty in all conditions of society, and were a difficulty now. The matter would gradually solve itself. Absolute, complete, and unfettered democracy in the ideal sense was coming; but they were not ready for it now.

The lecturer was thanked, and the meeting ended.

COLOUR PHOTOGRAPHY "AN ESTABLISHED FACT."

(Philadelphia Public Ledger.)

A large audience of ladies and gentlemen, which crowded the hall of the Franklin Institute last evening, heard a most interesting lecture by Mr. William Jennings, on the beauties and wonders of the Yellowstone region, and witnessed, thrown upon a screen, a fine collection of photographic views, in which Mr. Frederic E. Ives successfully reproduced the colours of nature. On August 9 last Mr. Ives and Mr. Jennings started from the Broad-street station of the Pennsylvania Railroad, fully equipped with cameras and kodaks for a four thousand mile journey, and they succeeded in capturing views of some of the grandest scenery in the country.

Mr. Ives, who was introduced by Professor Houston, said the greater portion of the illustrations shown were "snap-shots" made by Mr. Jennings, and the pictures, he said, would do credit to the best photo-

graphy. This assertion was strongly borne out by the enthusiasm of the appreciative audience. Mr. Ives also explained that he had remedied certain defects in his colour camera, and he had been so successful in obtaining open landscapes and other views as to convince former sceptics of the possibility of making photographs in the colours of nature. The limelight used last evening, he said, was not powerful enough to bring out the sunlight illumination, but the effect produced was intermediate between moonlight and sunlight. The occasion, he said, was the first in the world in which an attempt was made to illustrate a lecture with photographic pictures in the natural colours, and before the close of the season he meant to demonstrate the success attained with a greater variety of subjects.

Mr. Jennings then followed with the story of the trip, and told it in such a vivid manner as to fairly carry his hearers along with him. Some of the views shown were extremely beautiful, and when the last picture had been thrown upon the screen, the general feeling seemed to be that the reproduction of the colours of nature was an established fact.

A "PARALLACTIC" METHOD OF FOCUSSING.

["American Annual of Photography."]

Every one who uses a copying camera is well aware of the shortcomings of the ordinary ground-glass screen, when it is a question of accurate focussing. The difficulty grows as the scale of enlargements increases; and the employment of a magnifying-glass often serves only to make matters worse, as it exaggerates the inherent defects of the ground-glass surface to such a degree that the finer lines of the enlarged image are with difficulty seen, and with still greater difficulty brought to a satisfactory focus.

Examine a piece of ground glass with a microscope; it will be found to be not a plane surface by any means, but a very rough aggregation of hills and valleys, strewn all over with jagged points which reflect the light in all directions. Mathematical accuracy of focus cannot be secured on such a surface; we might as well expect to make fine micrometer measurements on a cobblestone roadway.

In the plan of focussing now proposed in this article, the focussing screen, as such, is discarded altogether (its office being merely to give a general idea of what will appear on the plate), and the image, formed in *space*, is examined and made clear and sharp by a specially made magnifier. The method is called a "parallactic" one, from its likeness to the well-known usage of astronomers in getting a sharp focus on a faint telescopic object. The working eyepiece of telescopes—as everybody knows who has peeped through them—have one or more fine lines stretched across the field, lying in the precise focal plane of the eyepiece. These lines are variously called "cross-hairs," "spider-lines," "contact-wires," &c. Now, when an observer at the eye end of a telescope wishes to assure himself that an object within the field of view is accurately focussed, he first brings it into contact with one of the cross-wires of the eyepiece. Then he moves his eyes very slightly from one side to the other, or up and down. If the observed object "wabbles" in the slightest degree as the eye changes place, the focus is at once known to be inexact. (For, unless the image and the wire are in the plane, there will be an apparent movement of the former, due to parallax.) But when, by moving the eyepiece in or out, a position is found in which the object seems quite stationary on the wire, the focus is perfect.

Now, to apply this procedure to the camera:

Get any optician to make what is known as a "positive eyepiece," magnifying, say, twenty or twenty-five times, with two cross-wires placed thus + at its focus. (Such eyepieces ought not to cost more than $5 each.) Around the tube of this eyepiece have a collar fitted—like the "flange" of a lens—so that when the collar, or flange, rests against the smooth face of the ground-glass screen, the cross-wires will be in the exact plane of its roughened or focussing surface, the eyepiece, of course, projecting through an aperture in the glass.

Instead of going to the trouble of boring a hole in the ground glass, the focussing screen could be made in two pieces or strips, leaving an open space as wide as the diameter of the eyepiece tube, along the median line (laterally or vertically, as found most convenient) along which the eyepiece slides; thus giving a choice of objects to focus on.

For example, an 8 × 10 focussing screen adapted in this way for use with an eyepiece of one inch outside diameter would be made of two strips each 3½ × 10 inches, fastened in the upper and lower halves of the containing frame, leaving a one-inch slot for the eye-piece to travel along. These strips are preferably made of *plate* glass with truly parallel surfaces, and they should be selected first of all, and given to the optician so that he can adjust the eyepiece flange to correspond.

To use:—

Get the picture approximately focussed on the ground-glass strips. Place the eyepiece in the groove. Move it about so that the cross-wires are in contact with any convenient object in the picture. Rack the focussing screen in or out until a movement of the eye in any direction produces no apparent displacement of the image on the wire. The focus is then accurate.

Clarence E. Woodman, Ph. D.

Our Editorial Table.

The American Annual of Photography for 1892.

London Agents: Hampton, Judd & Co., Farringdon Street, E.C.

In this *Annual* the New York *Photographic Times* has given us a volume which amply keeps up its high character. It is quite plethoric with illustrations, there being no fewer than twenty-four, representing various styles of printing. The text portion covers many phases of photography, and is contributed by American and English authors, whose names are well known. Elsewhere we give extracts from its pages. The name of the Editor does not appear.

Percy Lund & Co's. Plate Backing Papers and Print-drying Pads.

Messrs. Lund & Co. have submitted to us samples of non-actinic paper, coated with an adhesive substance. These will be found exceedingly effective for backing purposes. The same firm's print-drying pad consisting of a number of sheets of bibulous blotting-paper, placed between metal sheets, is an addition to the implements of the amateur's printing room of considerable convenience. The need of a means for easily drying and flattening prints is often experienced, and in these pads it is neatly supplied.

Fallowfield's *Remembrancer* for January, quite sustains its reputation for placing buyers *en rapport* with the newest introductions and appliances on the market at the earliest moment.

New Diaphragm Shutter.

Bausch & Lomb Optical Company.

This new American shutter has been introduced into this country by Messrs. Charles, Reynolds & Co., 72, Fore-street, London, E.C., who are the wholesale agents for it. The cut gives such a good illustration

of the shutter as not to necessitate much explanation. It can be set for time as well as for instantaneous exposures, and by rotating the disc at the top, the iris diaphragm can be set to any desired aperture, from the greatest to the smallest. The shutter is neat and elegant, and, as regards construction, is a fine specimen of mechanical excellence.

The Photographer's Diary and Desk-book for 1892.

James Blackmore, 55, Chancery-lane.

For several years past we have been happy to welcome the publication of this serviceable volume. In addition to a large collection of standard formulæ and other information likely to be of use to photographers, the diary portion, interleaved with blotting-paper, will be found very handy by business men. The book has, by way of frontispiece, a portrait of Mr. William Bedford, which is a capital likeness. Accompanying it is a short sympathetically written biography of the past President of the Convention, the fidelity of which will be instantly recognised and appreciated by that gentleman's many friends.

Lantern Slides and How to Make Them.

By A. R. Dresser.

The second edition of this manual (published, as before, by the Fry Manufacturing Co.) has received several additions at the hands of the author, and now numbers fifty-six pages. In this edition Mr. Dresser gives directions for toning slides by the uranium and ferridcyanide process, presumably already known to most of our readers. But such directions, coming from a practical man like the author, will ever be received with interest. The *brochure* is written in a pleasant style.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
January 11	Darlington	Trevelyan Hotel, Darlington.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

December 31,—Mr. C. H. Cooke in the chair.

Messrs. A. J. Campbell, J. Cole, and G. T. Harris were unanimously elected members of the Association.

Mr. J. Traill Taylor presented a copy of The British Journal Photographic Almanac for 1892, and Mr. H. E. Davis *The Tannin Process*, by C. Russell, for the Association's library. The donors were thanked.

Mr. W. E. Debenham exhibited a glass-cutting board of his own contrivance. The gauges were hinged together, and folded back. The size of the board was 10 × 12. The gauges together measured eight and a half inches, and cuts to that size, and to six and a half inches, four and three quarter inches, four and a quarter inches down to one and five eights of an inch could be made by turning back the flaps as required.

Mr. G. W. Atkins showed a number of lantern slides developed with the rodinal developer distributed at a previous meeting. He had found it very quick in action.

Mr. A. Haddon inquired the grounds upon which Mr. J. Weir Brown considered the pictures produced by his new uranium toning process permanent. Hypo and potassium ferridcyanide were used to dissolve out the silver, and this necessitated prolonged washing, which would remove the image. A dilute solution of acetic acid would retain the uranium image, but this could not be used on account of the hypo. In consequeace of these toning experiments uranium would probably be used a great deal in future. Uranium nitrate was not a very cheap salt, and it might be useful to know how to save the residues. The Eastman Company, in their uranium toning instructions, advised the emptying of the used solution down the sink. He (Mr. Haddon) thought it would be better to use a small quantity of a cheap salt to enable one to recover the uranium. If a small quantity of potassium ferrocyanide were added to the used toning solution, it would throw a deposit of ferrocyanide of uranium. On some future occasion he would give a method of converting the uranium ferrocyanide into nitrate.

Mr. T. E. Freshwater, in connexion with the permanency of bromide prints, quoted from a letter he had received from a friend residing among the Himalayas complaining that some bromide prints issued as book illustrations during the last five years were badly faded, and, in some cases, nearly obliterated. The silver print, issued with Abney and Robinson's silver printing, was nearly as good as when issued. Platinum prints, when mounted behind glass, developed a fungoid growth over the surface. Some 12 × 10 albumen prints showed no change, although the mounts had yellowed. They were made from vigorous negatives, and the paper sensitised in a fifty-grain bath. They lasted longer and were better than the prints now issued in fine black tones.

Mr. T. Bolas observed that there was one condition under which no silver print would not fade. In referring to silver prints he excluded prints toned with gold. The condition most destructive to permanency was the presence of sulphuretted hydrogen. If silver prints were kept in a damp place, sulphuretted hydrogen would be formed, and destroy the print. It was the custom of paper-makers to search for substances for tenacious fibres, and sulphate of lime had long been used. The action of moisture and organic matter on sulphate of lime produced sulphide of calcium, caused by the organic matter of the paper reacting with the lime, and so forming the sulphide. The carbonic oxide or dioxide of the atmosphere deposited carbonate of lime and free sulphuretted hydrogen in the paper. They knew that any ordinary book, if put in a damp place, would soon smell of sulphuretted hydrogen. Sulphate of lime being reduced to sulphide, the reaction of the latter with carbon dioxide liberated sulphuretted hydrogen, which no silver print would stand; for all silver prints would fade under the action of sulphuretted hydrogen. The presence of sulphate of lime in papers and mounts would account for the fading of silver prints. The sulphide of silver formed was dark, if there was enough of it; but probably it was oxydised into sulphate, and became diffused through the paper, which would account for the fading of the prints. In time the whole of the silver would be diffused through the book. It had been said that the paper of the books referred to, when sent out, was damp. A damp book, put on a dry shelf, would be mouths before it was dry.

The subject for the evening was *Warm Tones on Lantern Slides*, and Mr. Cowan observed that he found no difficulty in getting warm tones with chloride plates. With bromide plates he recommended the use of carbonate of ammonia in the developer.

Mr. J. Traill Taylor exhibited several slides produced by various methods. One, which had a beautiful warm tone, produced either by mercury followed by ammonia, or sulphide of ammonium, had, as they could see, faded very much. There was another in the act of disappearing. Some, made in 1868 by wet collodion were toned by immersion in a weak solution of potassium sulphide, and were quite as good now as when done.

Mr. Bolas asked Mr. Taylor if he thought the whole of the image was converted into silver sulphide, or whether another compound was formed which might be more stable than the normal sulphide?

Mr. Taylor said probably such a compound was formed. In reference to one of the slides, he might say that Fox Talbot had borrowed it of him, in order to engrave it by photoglyptography. He did not undo it, but got excellent sharpness, employing a light which gave no parallax. He placed it in contact with the steel plate, and sent the light through the glass. The result was perfectly sharp, having the light at a considerable distance. The small beam of sunlight used gave no parallax.

Mr. Bolas thought the method quite practicable, and referred to the making of a single carbon print by printing through the glass at the bottom of a box two feet deep, pointed towards the sky.

Mr. W. Coles inquired if the method would do for larger sized prints.

Mr. Bolas replied in the affirmative, and said a single print produced by that method would be good enough for ordinary purposes.

Mr. Taylor said that he had borrowed a hint from Fox Talbot in printing wet-collodion transparencies separated by strips of paper or cardboard. The sharpness was excellent, the light being the limelight, placed at a considerable distance away.

Reverting to the subject for the evening, Mr. E. W. Parfitt asked if the illuminant employed had anything to do with warm tones?

Mr. W. Bedford thought the tones of lantern slides were influenced by the developer, and not, as some thought, by the exposure. If, as had been said that evening, the illuminant were the cause of the different tones, they might soon hope for pictures in natural colours.

Mr. Beckett alluded to a remark of Mr. Wellington's at a previous meeting, alleging that the tones on bromide prints were affected by exposure. He supposed this applied to plates as well.

After some further remarks by Messrs. Debenham, Everitt, the Chairman, and others, the meeting terminated.

Camera Club.—December 31.—Mr. T. M. Brownrigg exhibited a collection of his slides, including scenes in London, catbedral interiors, and landscapes. Amongst the latter, which were mostly from hand-camera negatives, were some pictures of subjects taken on the Wey and around Guildford. Mr. Brownrigg gave the most entertaining and amusing descriptions with his pictures. Other slides were shown by Messrs. Frank Howard, Williams, Howlett, Patterson, Burchett, and Lieut.-Colonel Gale. On January 14, a paper will be read by Mr. J. Howson, entitled, *The pros and cons of Chloride Printing.*

North London Photographic Society.—January 5, Mr. J. Traill Taylor in the chair.—After the presentation of The British Journal Photographic Almanac, 1892, by the President, a circular from the Photographic Society of Great Britain was laid before the Society, and Mr. A. Mackie was appointed a delegate to represent the Society on the Affiliation Committee. The evening being occupied as a technical night, several members brought objects of interest, among them Mr. A. E. Smith, who showed some very successful carbon prints, and also some negatives of electric sparks. Mr. Coventon asked the solubility of carbonate of lithium, and it was stated, on the authority of Mr. Cowan, to be

four grains to the ounce. Mr. A. E. SMITH asked if Dallmeyer's new lens would be suitable for copying. Mr. MACKIE pointed out that the field would be too small for practical use. Mr. GROVER showed some bromide prints, toned by Mr. Weir Brown's process. The prints had been developed by ferrous oxalate, and, owing to insufficient clearing, were rapidly yellowing in the whites. It was suggested that the reason why hydroquinone was recommended in this process was probably owing to the difficulty of thoroughly removing the iron salts. Mr. COVENTON brought an old stereoscopic shutter on the roller-blind principle, bearing Dallmeyer's name, and believed to be of the date of about 1861. Mr. PARFITT mentioned that Mr. Beard had made for him a safety apparatus, for preventing explosions in pressure gauges, the entrance to the gauge being closed by a screw having a slight passage in the threads, preventing any sudden pressure. Mr. GROVER stated that the principle had been adopted before in a well-known water valve, which was now superseded. Mr. GROVER described a series of experiments which he had made to produce explosions by pressure of oxygen from a cylinder in presence of a number of different substances, such as iron, steel, and brass filings, as also scraps of leather, and a few drops of oil, the result being that with the leather, as well as with the oil, there was a violent explosion, sufficient to have destroyed any gauge which might have been attached.

Croydon Camera Club.—January 4, the President (Mr. H. Maclean F.G.S.) in the chair.—*Platinum Printing*, by Mr. B. GAY-WILKINSON. By means of prints taken from such notable negatives as *The Shrimper*, *The Ebbing Tide*, &c., Mr. Wilkinson explained, without *arrière pensée*, how he works the platinum process so successfully as to carry off the "blue ribbon" of the photographic world, which he has done more than once. It is needless to describe the manipulations gone through, but one point that is noteworthy is the thin character of the negatives worked with. These, being developed by pyro-ammonia, no doubt have a greater range of density than is noticeable to the eye, but none the less Mr. Wilkinson's negatives are not vigorous and sparkling, as we are often told they should be for the platinotype process. Specially was this flatness noticeable in the case of an evening effect upon the seashore, which, nevertheless, yielded a print which, produced on this occasion for the first time, is likely to be seen a good deal more of on the walls of future exhibitions. Following the demonstration, Mr. Wilkinson showed a number of his lantern slides, interspersing these illustrations with many useful hints and interesting anecdotes. It may be serviceable to readers to know that Mr. Wilkinson's masterpieces were all done on Wratten's plates, and his lantern slides are Mawson's, by reduction from 10 × 8 and over. As important subsidiary aids to success, he believes in unsparing trimming and rough paper. He does not use a hand camera.

Richmond Camera Club.—January 1, Mr. Cembrano presiding.—Lantern night.

Cheltenham Photographic Society.—December 22.—General F. Dawson and Colonel H. M. Saunders gave a demonstration of Enlarging and Reducing by Limelight, working with Mr. Hughes's Bijou half-plate enlarging lantern. The chief object the demonstrators had in view was to show that with no other apparatus than Hughes's patent rectangular condenser and a small camera reductions from half and quarter-plate negatives could be made with ease and certainty, and without daylight, the ordinary writing-table being used, and with an exposure of from four to ten seconds, according to the density of negative. A negative was selected having considerable density in the middle and with rather weak marginal definition. The exposure was judged to be eight seconds, with blow-through jet and Thomas's lantern-slide plate. Developed with three grains of quinol, three grains of hydrate soda, and half a grain of bromide, the exposure was found to be correct. The advantages of this system were pointed out to be the compactness of the apparatus by using the rectangular condenser; this was the same size as an ordinary half-plate or 6½ × 4¾. Nothing is needed but the condenser, fitted up as any one used to photographic manipulation might easily make for himself. The negative is placed close to the condenser, the small camera fixed at a proper height and at a proper distance from the negative, and the condenser then properly illuminated, which is seen by the ground glass of the small camera showing a clear and shadowless light. The negative is then inserted in its carrier, and the exposure made. The small camera is placed in position roughly by measurement, according to the scale of enlargements and reductions in any book of reference, and the fine adjustment made by the rack of the camera. The full seven-eighth opening of the lens was used, of rapid rectilinear class, six inches equivalent focus. An enlargement with the Bijou apparatus was then made with the full opening of the lens supplied from half plate to 15 × 12, the exposure being modified by shielding those portions requiring it, and prolonging the exposure on other portions. The negative was a very trying one, and was selected for that reason. An exposure of eighty seconds (about) over the whole picture, extending to two minutes for some rather hard water from a mill-race was sufficient. Any ordinary negative not requiring shielding would require about sixty to eighty seconds. The development was with Thomas Brothers' single solution quinol developer used weak, about one drachm to twelve drachms of water, which developed the enlargement satisfactorily and with a good colour.

Leeds Photographic Society.—December 21, Annual Meeting, Mr Godfrey Bingley (President), in the chair.—The following gentlemen were elected as members of the committee for the year 1892:—Messrs. Godfrey Bingley, W. A. M. Brown, Herbert Denison, E. H. Jacob, M.A., M.D., A. E. Nowell, Rev. E. S. Palmer, Robert Steele, T. W. Thornton, J. H. Walker, and S. A. Warburton. The thanks of the Society were given to Messrs. Butterworth, Rodwell, Thornton, and Warburton for the long and valuable services they had rendered to the Society. The officers for the year 1892 are as follows:—*President*: E. H. Jacob, M.A., M.D.—*Vice-Presidents*: Godfrey Bingley and S. A. Warburton.—*Hon. Librarian*: W. A. M. Brown.—*Hon. Lanternist*: J. H. Walker.—*Hon. Treasurer*: T. W. Thornton.—*Hon. Secretary*: Herbert Denison.—*Assistant Hon. Secretary*: Robert Steele.

Tyneside Camera Club.—December 15, the President (Mr J. F. McKie) in the chair.—A member read a paper on *Old and New Developers*, and showed what the separated ingredients of a developer were expected to do. In the discussion which followed, the PRESIDENT said that the new developers were like delicacies, but when we want good, steady work, we generally fall back on pyro-ammonia. January 19, *Enlarging, Copying, and Reducing, and the Apparatus*, by J. F. McKie.

Photographic Society of Philadelphia.—December 9, 1891, the President (Mr. John C. Bullock) in the chair.—A very large collection of interchanging slides from the Lantern Society of London, England, was shown. They are a remarkably fine set, and certainly one of the best collections ever sent to the Society in this manner. Mr. CHEYNEY called the attention of members to an interesting book which he had come across, published in Philadelphia in 1853. It was entitled *Plain Directions for Obtaining Photographic Pictures by the Calotype and Energiatype, &c.*; also *Practical Hints on the Daguerreotype*, by J. H. Croucher. He read various extracts from the book, which were interesting as contrasting some of the old-time photographic processes with those of the present day. Peculiar interest, however, was attached to one of the extracts on "Daguerreotype Panoramique," an account of recent threats said to have been made by M. Moissard to prosecute certain Americans for an alleged violation of his patents. The extract read as follows:—"*Daguerreotype Panoramique.*—This apparatus is constructed to admit of a view of considerable length and of extreme nicety of delineation, being taken with a lens of moderate diameter. The lens is made to have a horizontal movement, which brings it to bear successively upon every part of the horizon within 150°. Having been fixed so that the vertical lines of the object are perpendicular with a line drawn through the ground glass on which the focus is taken, the prepared plate is placed in a *flexible frame*, and retained in a certain curve by stops fixed to the frame. The lens is now turned to the extreme limit of the view to be taken, and then gradually and smoothly moved onward by a rackwork attached to the camera till it reaches the other extremity, waiting a longer or shorter time at each point as the object is more or less illuminated. The plates are prepared and fixed in the ordinary way. The use of this instrument is difficult, however, and requires considerable practice to produce good pictures." Mr. CARBUTT stated that, in view of the increase in stereoscopic work, it might be well to mention that a very simple way of making transparencies for the stereoscope consisted in the use of cut films with a matt back. To obtain a perfect stereoscopic effect, the negative has to be bisected and the views changed around. If the negative was taken on a film, it could readily be cut with a square and knife so that they would come together perfectly. Where glass plates were used, they had to be cut with a diamond, thereby running the risk of a rough edge. At the next meeting he intended to show some very good results in transparencies of the kind referred to. Dr. MITCHELL asked whether any of the members had tried the new developer, "para-amidophenol." He expected to show a few lantern slides at the next meeting made by this developer, which was claimed to be the coming developer. So far it was extremely expensive, the wholesale price being about thirty-five cents per drachm; but it was very powerful, and worked quickly and strongly in a very dilute solution, about one part to two thousand. It was particularly excellent for bromide paper, giving much better whites than could be obtained with oxalate.

RECENTLY ELECTED OFFICERS OF SOCIETIES.

(*Received too late for the* ALMANAC.)

ASHTON-UNDER-LYNE AMATEUR PHOTOGRAPHIC SOCIETY.—Established 1891. *President*: Dr. A. Hamilton.—*Vice-Presidents*: J. W. Kenworthy, C. E. Redfern, Rev. H. J. Palmer, Major Bradley.—*Committee*: W. Chadwick, T. Glazebrook, W. Greenwood, R. Hall, W. Leigh, R. Matthews, J. H. Storey, G. Wells.—*Exhibition Sub-Committee*: Messrs. Hamilton, Kenworthy, Palmer, Marsland, Glazebrook, and Candelet.—*Treasurer*: R. T. Marsland.—*Hon. Secretary*: G. H. Dean, 8, Egmont-terrace, Stalybridge.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.—Established 1885. The Society meets second and third Thursday at Half-past Seven at the Lecture Room, Midland Institute, each month October to April, and fourth Thursday only during the five summer months except Lantern Nights, when meetings are held at the Young Men's Christian Association Room, Needless Arley. *President*: J. B. Stone, J.P.—*Vice-Presidents*: W. J. Harrison, F.G.S., E. H. Jaques, J. J. Button.—*Council*: F. S. Goode, W. Jones, A. J. Leeson, A. R. Longmore, G. A. Thomason, T. Taylor, E. E. Underwood, G. Wilkes,—*Librarian*: W. S. Horton.—*Treasurer*: W. Rooke.—*Secretaries*: J. T. Mousley, 26, Portland-road, Edgbaston; A. E. Tucker, 5, Paradise-street.

BOURNEMOUTH SOCIETY OF NATURAL SCIENCE (PHOTOGRAPHIC SECTION).—Established 1889. *President*: Dr. Hyla Greves.—*Vice-President*: Rev. J. R. Husband, M.A.—*Committee*: Rev. G. H. West, D.D., S. Hardwick, F. W. Cory, P. H. Price, G. Piercy, G. Schofield.—*Treasurer*: W. Dolomore.—*Secretary*: William Jones, 203 and 205 Old Christchurch-road.

BROOKLYN ACADEMY OF PHOTOGRAPHY.—Incorporated February, 1887. The Business and Social and Working Rooms are located in the Brooklyn City Safe Deposit Company's Building, 177 and 179 Montague-street. The Lectures are given in the Hoagland Laboratory, Henry-street, corner of Pacific-street. Business Meetings are held the second Wednesday evening of each month at Eight p.m. Annual Meeting second Wednesday in February at Eight p.m. *President*: Frank La Manna.—*Vice-Presidents*: Gonzalo Poey, William Arnold.—*Council*: the Officers and J. Merritt, M.D., George S. Wheeler, Starks, W. Lewis, T. R. Mills, H. Allen Smith, R. N. Dennison, M.D.—*Treasurer*: Edward H. Quantin.—*Recording Secretary*: Hermance Tremper, West Brooklyn.—*Corresponding Secretary*: Harry S. Fowler, 578, Halsey-street, Brooklyn, New York.

CASE SCHOOL CAMERA CLUB.—Established 1888. *President*: Henry J. Leuke.—*Vice-President*: Arthur G. Bishop.—*Treasurer*: Percy W. Cobb.—*Secretary*: Robert B. Smith.—*Corresponding Secretary*: Cass L. Kennicott, Case School of Applied Science, Cleveland, Ohio.

CYCLISTS' PHOTOGRAPHIC PORTFOLIO CLUB.—A Circulating Photographic Club, numbering at present thirty members. Four portfolios are circulated from member to member, each member changing his prints and criticising

those of others when the portfolio reaches him. *Secretary:* W. L. J. Orton, 7, Bishop-street, Coventry.

CREWE SCIENTIFIC SOCIETY, PHOTOGRAPHIC SECTION.—Meetings held at Mechanics' Institute monthly. *President:* A. H. Hignett, Esq.—*Committee:* W. Allwood, J. S. Hough, J. Lewis, H. J. Parkinson, F. S. Ransome, F. C. Tiple.—*Hon. Secretaries:* W. Bispham, 60, Samuel-street, and Joseph Laing, Victoria-street, Crewe.

DERBY PHOTOGRAPHIC SOCIETY.—*Secretary:* Thomas A. Scotton, 9, Church-street, Derby.

LIVERPOOL PHYSICAL SOCIETY, PHOTOGRAPHIC SECTION.—Established 1890. *President:* F. Hurter, Ph.D.—*Treasurer:* C. A. De Seux.—*Secretary:* Charles A. Kohn, Ph.D., B.Sc., University College, Liverpool.

MUNSTER CAMERA CLUB.—Temporary rooms, Crawford Municipal Schoo of Science and Art, Nelson's-place, Cork. *President:* Major J. Douglas Lysaght, A.P.D.—*Vice-Presidents:* Ringrose Atkins, M.A., M.D., Denny Lane, M.A., Henry S. Noblett.—*Committee:* Richard S. Baker, John Bennett, James Bradshaw, John Day, Richard Foley, Patrick Hallinan, William Harrington, Henry Lund, Rev. James O'Mahony, Kingsmill B. Williams.—*Hon. Treasurer:* William R. Atkins, F.C.A., 39, South Mall, Cork.—*Hon. Secretary:* Denham Franklin, J.P., 74, South Mall, Cork.

THE NATIONAL ASSOCIATION OF PROFESSIONAL PHOTOGRAPHERS OF GREAT BRITAIN AND IRELAND.—Established February 13, 1891. Ordinary Council meetings every three months. Annual meeting, second Thursday in February. *President:* H. J. Whitlock (Birmingham).—*Vice-Presidents:* T. Fall (London), Chevalier Lafosse (Ilfracombe), R. Slingsby (Lincoln), J. E. Shaw (Huddersfield).—*Committee:* W. Barry (Hull), W. Bedford (London), T. Birtles (Warrington), Warwick Brookes (Manchester), J. E. Bruton (Douglas, Isle of Man), J. Chancellor (Dublin), T. Storey Davis (Halifax), Debenham (London), J. E. Eddison (Barnsley), J. Elliott (Elliott & Fry, London), J. Fergus (Largs), — Guy (Cork), William Gill (Colchester), R. P. Gregson (Blackburn), Lafayette (Dublin), Abel Lewis (Clifton), Donald MacIver (Leeds), John Moffat (Edinburgh), C. Pettingall (Liverpool), Frank M. Sutcliffe (Whitby), Carl Vandyke (London), H. Vanderweyde (London), F. M. Whaley (Doncaster).—*Hon. Treasurer:* J. Crosby (Rotherham).—*Hon. Secretary:* C. P. Richards (Barrow-in-Furness).—*Secretary:* D. J. O'Neill, 47, Charlotte-road, Birmingham.

NEW ORLEANS CAMERA CLUB.—*Pres dent:* L. E. Bowman.—*Vice-President:* P. E. Carriere.—*D rectors:* The officers, and Miss Gladys Rueff, B. C. Shields, R. H. Palfrey, J. A. Streck, G. N. Maxent.—*Treasurer:* W. M. Rhodus.—*Secretary:* R. S. Charles, jun., Cotton Exchange Building, New Orleans.

OLD COLONY CAMERA CLUB.—Established February 1, 1890. *Pres dent:* David Smith.—*Vice-Pres dent:* Fred Aines.—*Secretary and Treasurer:* H. W. Stuelly, Rockland, Mass., U. S. A. Box 210.

OLDHAM PHOTOGRAPHIC SOCIETY.—Established 1867. *President:* W. Thompson.—*Vice-President:* J. Chadwick.—*Committee:* J. H. Ashton, J. Brooks, J. S. Dronsfield, J. Greaves, jun., T. Heywood, W. Jackson.—*Librarian:* L. Tetlow.—*Treasurer:* W. Schofield.—*Hon. Secretary:* Thomas Widdop, 16, Burnaby-street, Oldham.—*Assistant-Secretary:* William A. Nash, 23, Queen's-road, Oldham.

OXFORD PHOTOGRAPHIC SOCIETY.—Established 1889. *President:* E. A. Ryman-Hall.—*Vice-Presidents:* C. C. Cole, A. F. Kerry, M.A., A. F. Stanley Kent, M.A., Councillor J. H. Salter.—*Committee:* N. G. French, W. J. King, G. W. Norton, H. M. Phillipps, W. H. Price, M.A., A. Robinson, G. A. Smith.—*Hon. Treasurer:* James Minn, 105, Walton-street.—*Hon. Secretaries:* F. A. Bellamy, 4, St. John's-road; H. Minn, 105, Walton-street. Official address, 136, High-street.

PHOTOGRAPHIC ASSOCIATION OF BROOKLYN.—March, 1887. *President:* Dr. E. H. Riedel.—*Vice-President:* E. F. Wagner.—*Committee:* Dr. E. Routh, Dr. F. A. Schlitz, W. Lang.—*Treasurer:* J. A. Gafney.—*Secretary:* Charles M. Heid, 54, Stone-street, N.Y. City.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.—Place of meeting for 1892, Edinburgh. *President for the year:* George Davison.—*Council:* W. Middleton Ashman (Bath), W. Bedford, *past President* (London), T. Berry (Aberdeen), J. J. Briginshaw (London), C. H. Bothamley (Taunton), F. A. Bridge (Dalston), A. A. Carnell (Plymouth), A. Cowan (Southgate), H. A. Hood Daniel (Bristol), R. P. Drage (London), F. Evans (Chester), A. L. Henderson (Lewisham), A. Haddon (Greenwich), M. J. Harding (Shrewsbury), H. M. Hastings (London), R. Keene (Derby), Austin J. King (Limpley Stoke), P. Lange (Liverpool), W. Lang, jun. (Glasgow), A. M. Levy (London), C. Phipps Lucas (Eltham), E. Marlow (Birmingham), G. Mason (Glasgow), A. Mackie (London), T. Mayne (Liverpool), W. W. Naunton (Shrewsbury), J. Porritt (Leicester), A. Pringle (Bexley Heath), B. J. Sayce (Liverpool), A. Seaman (Chesterfield), J. Smith (York), H. Sturmey (Coventry), J. Stuart (Glasgow), J. Traill Taylor (London), A. Tate (Belfast), J. M. Turnbull (Edinburgh), W. H. Walker (London), G. W. Webster (Chester), J. B. B. Wellington (Harrow), A. Werner (Dublin).—*Hon. Secretary:* F. P. Cembrano, jun., 10, Cambridge-gardens, Richmond, Surrey.

PHOTOGRAPHIC SOCIETY OF JAPAN.—Established 1889. Annual meeting is held in the month of May. Ordinary meetings are held about once a month, but there is neither fixed time nor place. *President:* His Excellency Viscount T. Enomoto.—*Vice-Presidents:* His Excellency Viscount N. Okabe, His Excellency H. Watahabe, Professor D. Kikuchi, M.A., Professor C. D. West, M.A.—*Committee:* All officers and K. Ogawa, Y. Ishizo, M. Kaljima, J. B. Rentiers.—*Treasurers:* A. J. Hare, Y. Isawa. *Secretaries:* Professor W. K. Burton, 9, Kaga Yashiki, Hongo, Tokio; Ishikawa, 218, Kanasuginura, Kitatoshigori, Tokio.

POLYTECHNIC PHOTOGRAPHIC SOCIETY.—Established 1891. Meetings are held first and third Fridays in the month at the Polytechnic, 309, Regent-street, at eight p.m. Annual general meeting in September. *Committee:* W. E. Brown, A. Crossley, O. J. Goose, F. J. Lock, J. E. Mothiron.—*Treasurer:* F. W. Jackson.—*Secretary:* Frederick R. Tissington, 105, Shafterbury-road, Crouch-hill, N.

QUEENSLAND AMATEUR PHOTOGRAPHIC SOCIETY.—Established 1888. Club room at Courier-buildings, Queen-street. Ordinary meetings held on first Friday in each month. *President:* F. R. Hall.—*Vice-Presidents:* J. Thomson, M.B., J. W. Sutton, D. T. Lyons.—*Committee:* W. J. Buzzacott, J. J. Knight, A. Clarke.—*Librarian:* E. H. Alder.—*Treasurer:* J. Campbell.—*Hon. Secretary:* A. R. L. Wright, Telegraph Chambers, Queen-street, Brisbane.

ROCHDALE AND DISTRICT PHOTOGRAPHIC SOCIETY.—Established 1890. *President:* John A. Bright, Esq., M.P.—*Committee:* Rev. T. P. Spedding, R. M. Jones, Beaumont, Blomley, Hoyle, O'Neill. *Treasurer:* Thomas Leach. *Secretaries:* W. and S. Ingham, 30, Freehold-street, Rochdale.

SOCIÉTÉ VERSAILLAISE DE PHOTOGRAPHIE.—Established 1884. Meetings on the first Tuesday of the month at the Town Hall. *President:* Maurice Bucquet.—*Vice-President:* Leon Ottenheim.—*Treasurer:* — Gavin.—*Secretary:* A. Hue, 28, Rue de Satory.

SOUTHPORT SOCIAL PHOTOGRAPHIC CLUB.—Meetings every Wednesday at Eight p.m., at Mr. Cross's studio, 15, Cambridge-arcade. *President:* Robert J. Parkes.—*Vice-Presidents:* Alfred Dunmore, A. Quayle.—*Committee:* Miss Unsworth, Miss Dunmore, J. R. Cave, G. Cross, C. Depree, J. C. Smith.—*Secretary and Treasurer:* G. R. Cartmel.

SYDENHAM CAMERA CLUB.—Established 1890. Meetings are held alternate Tuesdays at Eight p.m., at the headquarters, the Greyhound Hotel, Sydenham; outings during the summer months; annual meeting the last in the year. *President:* C. D. Budd.—*Council:* C. D. Budd, T. Cole, H. H. Gray, T. W. Rumble.—*Secretary and Treasurer:* H. H. Gray, 9, Thicket-road, Anerley, S. E.

TECH CAMERA CLUB.—Established 1890. Meetings on Saturday evening at Half-past Seven o'clock at the Institute; annual meeting at call of President. *President:* Edward H. Keith.—*Vice-President:* A. C. Higgins.—*Committee:* A. H. Smith, H. Sinclair, E. C. Kent, H. Bracken.—*Treasurer:* H. A. Coombs.—*Secretary:* E. W. Naill, jun., c/o W. P. J., Worcester, Mass., U.S.A.

WIGAN PHOTOGRAPHIC SOCIETY.—Established 1890. *President:* H. H. Wragg.—*Vice-President:* J. A. E. Lowe.—*Council:* Rev. J. S. Barnes, W. A. Varley, J. H. Atherton, R. Wardman, J. Smith, W. Heaton, F. Hughes.—*Secretary and Treasurer:* Fred. Betley, 11, Swinley-road, Wigan.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

ASTRONOMICAL PHOTOGRAPHY WITHOUT A TELESCOPE.

To the EDITOR.

SIR,—I thought at the time that Mr. Dallmeyer's wonderful new invention was nothing more than Barlow's lens. Now that we have heard Mr. Dallmeyer at the Camera Club, we see that it is so. If I mistake not, Jeremiah Horrocks used precisely the same combination when he obtained a shadow on paper of the first observed Transit of Venus, more than two centuries ago.—I am, yours, &c.,

HENRY ROGERS.

23, *Chancery-lane, January* 5, 1892.

THE PHOTOGRAPHIC SOCIETY.

To the EDITOR.

SIR,—Mr. H. P. Robinson gives the lie direct to Mr. Mackie's statement, confirmed, however, by the evidence and Mr. H. A. Lawrance, and crudely puts the matter as one of veracity on one side or the other. Does Mr. Robinson forget that he has (in *Photography* of the 24th ult.) admitted that he indicated the "place of honour," though he places it earlier in the day than the time at which he pointed out where he wished his own pictures hung on this favoured wall?

The mere selection by Mr. Robinson of a good place for his pictures is not in itself of much moment. They probably deserved, and would have obtained, a good position independently. The grand thing is that the Society has shaken off the system whereby an influential member could be present at and influence the hanging without his name appearing, or its being known to the members and exhibitors.—I am, yours, &c.,

January 4, 1892. W. E. DEBENHAM.

A NEW DEPARTURE IN PHOTOGRAPHY.

To the EDITOR.

SIR,—My attention has only to-day been called to the review of my book, on Gelatino-chloride Printing, in the *Daily Chronicle* of the 28th December, and to Mr. Howson's remarks thereon in your issue of to-day's date.

It is not my intention to enter into this controversy regarding the superiority of the various makes of gelatino-chloride papers, as I am not interested in the sale of any of them, nor am I in want of a cheap advertisement. But there is one point in Mr. Howson's letter which I feel must be cleared up at once. He explains that the reason why my book does not contain any mention of the Ilford paper is that only those papers are mentioned whose manufacturers paid for advertisement space therein.

I am willing to believe that this statement is due to Mr. Howson's ignorance of the fact that, when I was compiling the book in question, I

wrote to the Ilford Company, asking them to give me full particulars of their new paper, as I was anxious to make the work as complete as possible, and I received reply that they were not in a position to give me any particulars concerning their paper.

With regard to the appendix of the book I have nothing whatever to do. I did not know of its addition until after the publication of the book.

In the text, for which I am responsible, I do not think that I have given any undue prominence to any make of paper, and the only reason why the Ilford Company's production was not mentioned is entirely due to the cause already stated.—I am, yours, &c., WALTER E. WOODBURY.

Watford, January 1, 1892.

HAVE GELATINO-BROMIDE PLATES BENEFITED PHOTOGRAPHY?

To the EDITOR.

SIR,—I was glad to see your article on this subject, with most of the conclusions of which I find myself in perfect agreement; but, as to your concluding remark, relegating to uncertainty whether gelatine plates have benefited photographers themselves, I fear it is only too true that they have both directly and indirectly injured large numbers of them. Many who were *facile principes* with wet plates in all branches of work have quite failed to adapt themselves to the altered methods of procedure necessitated by gelatine. Contrary to what many would contend, this is their misfortune, and not their fault. The faculty of self-adaptation to all circumstances as they arise is not possessed in a larger degree by photographers than by other people, among whom, as we all know, it is none too highly developed. I am sure, Sir, most of us know several photographers of the old school whose businesses have steadily diminished since the introduction of gelatine plates, absolutely through no fault of their own. After all, I submit that the doctrines of the survival of the fittest, and that competition is the soul of trade, are cruel and inhuman in practice. In all revolutions, photographic or otherwise, somebody is bound to go to the wall, and this has certainly occurred in the case of gelatine plates. *En revanche*, finality is probably not yet reached. Who knows how soon gelatine plates themselves may share the fate of collodion?—I am, yours, &c., GEORGE WHITWORTH.

Seven Sisters-road, N., January 4, 1892.

BLISTERS.

To the EDITOR.

SIR,—Mr. Denmore writes, p. 15: "I feel convinced that the cause is in the preparation of the paper before it comes into the hands of the sensitiser," and so do I. Just a little evidence to confirm this opinion may be interesting. In a drawer in my den may be found a quantity of albumenised paper of a well-advertised, and therefore well-known, brand, purchased from a leading London dealer, who was requested to supply the best; the storage of the paper may be called equable, neither too hot, too cold, too dry, nor too damp; the sheets packed flat, and, having been at least a twelvemonth in my possession, may fairly meet the condition of seasoning by age. I will cut two pieces of paper from separate sheets, sensitise them together on a plain sixty grain silver bath, print under the same negative, wash, tone, and fix together in the same dishes, and, after transfer to the final washing water, I find one print suffering in the worst stage of a bad attack of small-pox, whilst the other is smooth, soft, glossy, perfect. It is quite just to the albumeniser of the "twinkle, twinkle" brand to admit that he can make good paper *when he likes*.

A brief and dogmatic paragraph (ALMANAC p. 575) was written for the numerous company of photographers, both professional and amateur, who pay for good paper and don't get it, and then—bless their innocence!—think the fault is all their own, and seek for and apply remedies, possible and impossible, whilst the albumeniser looks on and laughs in his sleeve. —I am, yours, &c., H. K.

Bishop Auckland, January 4, 1892.

HAS PHOTOGRAPHY BENEFITED ARTISTS?

To the EDITOR.

SIR,—If I might be allowed to make a few observations in reference to the "Flather *versus* Debenham" controversy, lately brought to a conclusion in your columns.

It seems evident to me, from the tone of Mr. Flather's letters, the last one especially, that there exists in some circles a suspicion that an outsider might not be fairly treated, or allowed the same privileges as other correspondents who have the interests of your JOURNAL at heart. But, in this instance, no one can doubt that you have given both sides an equal chance. Forgive me if I have entertained this notion myself, but I have seen good reasons for it in some of your contemporaries.

Perhaps this may, to some extent, account for some of the extraordinary assertions and arguments put forth by some of your correspondents under the heading of "Photography, and its claims to the title of Fine Art" remaining unrefuted. This one-sided state of things may be satisfactory to some biassed minds, but at the same time must deprive such articles of much real merit.

One portion of Mr. Flather's letter appears to have been lost sight of, and, with your permission, I will make some comments upon it, viz., Do the discoveries made by photographers in the use of photographic apparatus teach anything to artists?

Now, from an outsider's point of view, if one were to form an opinion of photographers in general from much that emanates from photographic societies, and even some professionals, one could only conclude that a more inconsistent body of men never existed. For while they are continually advocating the claims of photography to the elevation of fine art, they take up a most unaccountably hostile attitude towards artists themselves, who are really the promoters of what photographers claim to be the very essence of their own profession, and whilst anxious to assume the rank of artists before the public in general, seem to altogether discard the means by which such a position is attained, namely, qualification by art training; in fact, they want the honour without the hard work and study, and I think they find theory alone a very poor support in matters of real art.

How many photographers are there who even hold school certificates for model, freehand drawing, geometry, and perspective, or give any proof of mere elementary art training? How many are there who can retouch their own negatives (without spoiling them), or paint, colour, or otherwise finish their own enlargements in an artistic manner? But you will often find them trying to invent some sort of machine to do it.

And then the question arises, Do they teach artists anything?

They will tell you they are the artists, others are only painters, "wielders of the brush," &c.; pallette and brushes are machines. Of course, everything is mechanical to their eye, and who can be surprised?

One thing photographers seem to forget altogether, and that is, in practising photography they are making use of other peoples' brains instead of their own, and when a good result is obtained should not the maker of the lens come in for a share of the credit, or the dry plate maker? and is there no thanks due to scientists who, by their arduous studies and labours extending over a period of many years, have brought photography to what it now is?

Is there any credit in getting a good pose of a clever actor or actress? And is there any amount of brain power required in producing an *instantaneous study*?

Has it never occurred to these writers that if photography was a suitable medium for the production of works of art, that an artist could adopt those means himself without consulting a camera and lens proprietor? Why should they monopolise the credit of photography? Surely they don't pretend there would be any difficulty in the way of an artist making use of it. And, may I ask, in whose hands could it be expected to yield better results than those of an artist, whose eye, trained by genuine work, can see at a glance what another might practice all his life without seeing?

If you merit the title of artist by your works, no one can deprive you of it. But artists would be cheap indeed if the only qualification necessary were to join a photographic society and criticise the "*artist painter*."

I think myself that the time is not very far off when photographers will have to qualify themselves as artists, or take a back seat, and then perhaps we shall not see so many advertisements in the following style:—Wanted, a first-class operator and retoucher, clever with children (nurse the baby in principal's absence, wash the pots, &c.). None but competent men need apply. 30*s.* a week and a permanency to a steady man.—I am, yours, &c., ARTIST WITH BRUSH, PENCIL, AND CAMERA.

January 1, 1892.

RECENT PATENTS.

APPLICATIONS FOR PATENTS.

No. 22,496.—"An Apparatus for Photographic Purposes." GRIFFITH DAVID HUGHES.—*Dated December 24, 1891.*

No. 22,510.—"Improvements in Photographic View Finders." CONRAD BECK and JOSEPH THACHER CLARKE.—*Dated December 24, 1891.*

No. 22,648.—"A Patent Carrier Frame and Dissolver for Single Optical Lanterns." J. E. CLARKSON.—*Dated December 28, 1891.*

No. 22,740.—"The 'Facile Princip' Camera. Improvement in Photographic Cameras." JOHN HENRY SMITH.—*Dated December 30, 1891.*

No. 22,758.—"An Improved Photographic Print Washer." GEORGE FREDERICK FIRTH.—*Dated December 30, 1891.*

No. 22,825.—"Improvements in the Method of and Means for Modelling by the aid of Photography." Complete specification. HERMANN PÖTSCHKE.—*Dated December 31, 1891.*

Exchange Column.

**** No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Will exchange 10×8 rapid rectilinear lens for six-inch condenser and limelight blow-through jet.—Address, SMITH & Co., High-street, Yeadon, near Leeds, Yorkshire.

Will exchange Rippingille's oil stove, for heating rooms (in good condition), for large skin rug and grass mat.—Address, H. W., 131, Graham-street, Penrith.

Wanted, 10×8 rapid rectilinear, or featherweight whole-plate camera; exchange, Oakley's patent Metamorphoser lantern and slides.—Address, F. COUCH, 11, Waterloo-crescent, Dover.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," *2, York-street, Covent Garden, London.*

ALCOHOL.—See our leader on the subject.

F.—Bromide of silver is soluble in ammonia.

LENS.—See Mr. Dallmeyer's paper in the present number of the JOURNAL.

GEO. LEIGHTON.—Mr. Clarke's address is 52, Queen's-road, Finsbury-park, N.

CHAS. IRWIN.—Lead is the best for the purpose. It is impervious to most reagents.

R. R. J.—You will find the subject of your communication dealt with in another column.

FELIX.—Try a lamp for burning magnesium ribbon sent out by Messrs Parkes, Son, & Rayment.

OPERATOR.—Print deeply, and use the chloride of lime toning bath given on page 788 of the current ALMANAC.

R. WALLIS.—Few, if any, professional photographers have given up the employment of pyro as a developing agent.

J. HUBERT.—As you are are personally outside the controversy, we think it better not to publish your letter. Thanks all the same.

PYRO.—The spots are evidently sulphide of silver, caused by hypo, probably in a powdered state, coming in contant with the negative.

BEXLEY HEATH.—It is a cleverly executed picture, but we cannot give the precise details beyond saying that it is done by a series of sliding vertical shutters.

A. M.—Two articles on *Photo-micrography*, by Mr. T. Charters White, pages 40 and 86 of the last volume of the JOURNAL, contain a great deal of useful information on the subject.

SCOTTY.—We do not clearly understand your description. If you send us a rough sketch, and indicate on it the aspect, we shall be pleased to advise you with regard to the design for the studio.

PALL MALL.—All publishers of photographic views supply views of the principal buildings in London. Any stationer, who supplies photographic views, if he has them not in stock, will procure any to order.

J. MATHEWS.—It is quite a matter of taste whether you use a solution of beeswax or French chalk for preparing the glass plates, to permit of removing the pictures after enamelling. Most persons employ the latter, because its application involves less trouble than the former.

D. ROBERTS.—If you have been making and selling an apparatus the same as that just patented, so much the worse for the patentee, for he has wasted his money on an invalid patent. He certainly cannot prevent you continuing to do what you did prior to his application for a patent.

L. GREY.—For potraiture by artificial light there is nothing to compare with the electric arc. If, however, your means will not permit of its adoption, you cannot do better than use magnesium, either as the flashlight, or by the combustion of the ribbon. The former is the most general *mode* just now. Excellent portraits can be obtained by its aid.

NOTTS complains very much that amateurs can obtain photographic materials at the same price as professionals, and considers that manufacturers should not supply any dealer, or any of the "stores" who do not make amateurs pay a higher price than they charge professional photographers.—This is quite a trade question to which there may be more than one side.

M. W.—From the description we doubt very much if the inconvenience is due to the use of the bichromate of potash. Usually, the first symptoms are violent itching of the skin at the back of and between the fingers, particularly at bedtime, or when the hands get unusually warm. Pains and swelling at the joints we have never heard of in connexion with the ill effects of the bichromate.

S. S. S. sends us a print from a negative of the interior of a church, and calls attention to a window showing in the picture that was at the side, and quite out of view of the lens. The window is fairly sharp and well pronounced. Our correspondent asks the cause of the "phenomenon?" The cause is a minute hole somewhere in the camera—probably the bellows—which has fulfilled the conditions of a "pinhole camera."

NEMO.—It is evident that the dark slides are not light-tight. They were, doubtless, made of ill-seasoned wood, and swelled with the damp; then you eased the shutters with glass paper. Consequently, when they became dry again, they no longer fitted the rabbets, and hence admitted light. If, instead of using the glass paper, the slide had been placed in a warm and dry place for a few days, they would have remedied themselves.

H. A. JACOBS.—The licence to use a still is 10s. a year, even for distilling water. It is quite possible to purify methylated spirit, but it is strictly against the law to do so. Any one doing it subjects himself to very heavy penalties, as well as forfeiture of all the appliances used. Any one licensed to use a still must admit the Excise officers at any time they choose to come, whether the still is in use at the time or not. Methylated spirit, free from mineral naphtha, can still be supplied for manufacturing purposes to those who have complied with the Excise regulations as to bond, &c., but only in large quantities, ten gallons being the minimum, we believe.

W. ALLWAY.—The Photographic Convention is not a society established to protect trade interests. You will have to take proceedings on your own account, if you are so advised. There is no assistants' association.

E. MARTIN.—We should recommend you to act on the advice of your solicitor. It is doubtful if, after the lapse of so long a time, you would recover any substantial damages from the infringers. The proper way would have been to have commenced summary proceedings at the time of publication for penalties. You might write to the Secretary of the Association mentioned, but it is somewhat doubtful if it would move in the matter now.

S. WARREN writes: "I have a lantern with four-and-a-quarter-inch condenser, fitted with a quarter-plate portrait lens. Can I use it for enlarging quarter-plate negatives to about fifteen by twelve, using the same lamp with which the lantern is fitted?—No; that is if the whole of the negative is to be enlarged, as the condenser will not evenly illuminate it. For enlarging a quarter-plate negative the condenser should be not less than five and a half inches in diameter to obtain even illumination.

S. W. writes: "I have just purchased, second-hand, a rolling press for 10×8 pictures, but the steel plate is very rusty, and the rust seems to have penetrated deeply into the metal. Will you please say how I can repolish it?"—If the plate is in the state described, we doubt very much if it can be repolished to be again serviceable. If time be of any value, it will certainly be much cheaper to purchase a new plate. Steel plates are supplied by all the dealers in printers' materials at a moderate price.

PHOTOGRAPHIC CLUB.—January 13, *Architectural Photography*. January 20, *Stereoscopic Photography*, Mr. J. Nesbit.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.—January 11, Exhibition of prize slides at half-past seven.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—January 14, Ordinary Meeting. January 21, Monthly Lantern Night. Visitors invited.

THE Richmond Camera Club will hold an Exhibition of Lantern Slides at the College Hall, Richmond, S.W., on January 15, followed by a musical entertainment.

THE West London Photographic Society's Exhibition opens to-day (Friday), and will be continued on Saturday. In the evening of the second day there will be a lantern exhibition.

THE LANTERN SOCIETY.—Meetings for January.—January 11, Commander C. E. Gladstone, R.N., on *Westminster Abbey*. January 25, Mr. C. F. Budenberg, of the firm of Schäffer & Budenberg, will give a paper on *Pressure Gauges*.

Mr. JONATHAN FALLOWFIELD writes: "Allow me to draw your special attention to what I think an interesting comparison of the prices of photographic chemicals in 1856 and 1892. Which of the photographic dealers can show a similar record from his own price lists?"

THE Fry Manufacturing Company are arranging a series of lectures and demonstrations for the next three months upon Bromide Enlarging, and the Manipulation of Rough Bromide Paper toned with Uraninm. Mr. Dresser will also give a lecture on Lantern-slide Making, and probably Mr. W. I. Chadwick one upon Stereoscopic Photography.

AT the last meeting of the North London Society, Mr. E. W. Parfitt exhibited a safety apparatus for oxygen ganges made for him by Mr. R. R. Beard. It consisted of a small device for closing the entrance to the gauge by a screw having a slight passage in the threads, which would prevent any sudden pressure. At the present time this contrivance should be extremely welcome.

HACKNEY PHOTOGRAPHIC SOCIETY.—January 14, Prize Slides; 28, *Autocopyist* Demonstration. February 11, *Illustrated Journalism*, Mr. T. C. Hepworth; 25, *On the Riviera* (lantern evening), Mr. A. L. Henderson. March 10, *Lenses, Points and Hints thereon*, Mr. W. P. Dando; 24, *Chemistry of Light*, Dr. Gerard Smith. April 14, *Isochromatic Plates* (Ilford), Mr. John Howson; 28, Members' Lantern Night and Auction. May 12, Annual Meeting.

CAMERA CLUB FIXTURES.—January 11, Elementary Lecture, No. 5 (postponed to this date from December 21), Mr. Lyonel Clark, on *Exposure*. 14, Mr. J. Howson, *The pros and cons of Chloride Printing*. 18, Evening for trial of slides. Members intending to bring slides are requested to notify the Hon. Secretary. 21, Mr. A. Maskell, *The Rendering of Quick Movement by Photography—Express Trains, Action of Animals, Movement of Waves and Clouds*. Illustrated. 25, Elementary Lecture, No. 6, by Mr. V. A. Corbould, *Silver Printing*. 28, Lantern evening. Series of slides by Lieut.-Colonel Gale. Other slides by members. February 1, smoking concert. 4, Mr. W. Willis, *Further Improvements in Platinotype*, with demonstration.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1654. Vol. XXXIX.—JANUARY 15, 1892.

EXHIBITION ETHICS.

Mr. P. H. Newman was one of the Judges at the last Photographic Society's Exhibition, and he performed similar functions at the Crystal Palace Exhibition, which was held earlier in the year. Thus qualified, he, the other evening, addressed the members of the London and Provincial Photographic Association on the subject of *Some Recent Exhibitions*. We print the paper elsewhere. It will repay perusal, by whomsoever in the world of photography it is read; and if it be studied, as it deserves to be studied, by those to whom its strictures and counsels are addressed, the author may, one day, have the unique satisfaction of realising that he has written with practical results. But in this case he will be exceptionally fortunate, and photographers will be swifter to accept good advice than they have hitherto been.

It is not every judge of a photographic exhibition that has the courage to lift the curtain in the manner that Mr. Newman has done, and he is therefore clearly entitled to our thanks—if only for the precedent he has been good enough to create. We should suppose, from this and other evidence, that Mr. Newman's connexion with photography is rather a recent one; indeed, it appears to us to unmistakably betray the fact. For instance, he allows that photographic exhibitions, if not unmixed blessings, are greater necessities than ever, if the amateur is to be recognised. Mr. Newman fails to indicate why exhibitions are more a necessity for the amateur than for the professional. He appears to think that in the long run the professional must beat the amateur badly; but he ought to know that in recent years, at any rate, the despised amateur's landscape work has, in particular instances, been of such a quality and order as to give rise to the wonder how the great majority of the exhibitions would have fared without it. It may be desirable that by exhibitions, medals, and competitions the amateur should gradually learn what he is made of, and how far he falls short of a high standard of excellence; but why limit these introspective opportunities to the unfortunate amateur? Are we to understand Mr. Newman as contending that such privileges are not needed or called for by professionals, and that these latter never require to be told how they fall short of a high standard of excellence? Mr. Newman's experience of photographic exhibitions must indeed be a meagre one to ensnare him into the expression of such narrow views and incomplete deductions.

We are quite at one with Mr. Newman in condemning the arrangement, or even the hanging of pictures on account of some fancied taste or eccentric novelty in the framing of them, and we trust with him that the light which he lets in upon the laxity displayed in the matter will obviate any recurrence of such proceedings. That at the now notorious Exhibition in Pall Mall last year a great many photographs were hung in defiance of their intrinsic claims to rigid exclusion, we lament also to have to agree with him; but this is, unfortunately, a feature not monopolised by the Photographic Society. We applaud the action of the Judges in drawing attention to the matter in their report, and we shall look with interest upon the effect which it will have upon future hanging committees in the elimination of photographs which never could have secured a place on the walls except through culpable neglect or favouritism, or absolute inability to discriminate between the good and the worthless.

Mr. Newman would lead us to infer that judges should look to the hanging committee for some guidance on the score of excellence of exhibits; but this is the first time we have heard that judges were desirous of having such information. To our thinking, the functions of a hanging committee are generally selective and not judicial, and the less "guidance" the judges have in the allotment of awards the better we think it will be for the impartiality of their distribution. To admit the principle that judges are entitled to regard pictures occupying the places of honour as attesting the good opinion of a hanging committee, and designed to assist them in arriving at their decisions, would, we think, seriously weaken the public confidence in the value and justice of those awards. As regards photographic exhibitions, the elements of discord are at present quite numerous enough without adding to them.

Mr. Newman's commendation of the disposition of pictures in groups, as adopted at the Crystal Palace, is a hint which with many others the Society would do well to weigh. In remarking upon the unsatisfactory position of retouching in relation to exhibition portraiture, he, whether consciously or not we do not know, places his finger upon a burning question which is in urgent need of settlement. Not merely in the interests of judges, but of exhibitors, of the public, nay, even of photography itself, it is high time that the exact place of retouching in portrait photography should be commonly agreed upon. When Mr. Newman frankly considers it wiser to recognise retouching as a necessity than to take up an attitude of indecision in regard to it, we think that he strikes what is the true keynote of the position; but we should also be pleased to have his views, as an artist and a judge, upon the morality, or even the expediency, of the touching up of the finished print, which has prevailed, and does prevail, to a great extent in photography.

Mr. Newman enters a plea in favour of tolerating photographs in exhibitions which pretend to be no other than more or less faithful memoranda of places and things. We devoutly hope Mr. Newman stands alone in this strange advocacy. If he was anxious to flood our exhibitions with the commonplace, the unimaginative, and the absolutely unlovely, he could not have chosen a better way to such an undesirable consummation.

A photograph of purely technical merit is out of place at a public display. Of what earthly charm or interest to the artistic public are the architectural drawings at the Royal Academy? But we have not space to follow Mr. Newman in this and other interesting points of discussion raised in his thoughtful and ably written paper. We cannot, however, conclude our article without regretting that he departed from his judicial *rôle* to strike in upon matters of purely personal interest, as he does in the last part of his paper. We had hoped that this unfortunate controversy would have died out without the intervention of those whom it least concerned.

DIRECT CARBON PRINTING.

A QUESTION that often suggests itself to some, when seeing the carbon process worked for the first time, is, why cannot the picture be developed upon the paper that carries the pigmented gelatine instead of having to transfer the coating to another support, and afterwards to a second one, if a non-reversed image be desired? At first sight the different transfers, simple though they be, appear to the novice an unnecessary complication. It is, however, quite possible to develop a carbon picture on the paper upon which the pigmented coating is supported, and thus do away with the operations known as single and double transfer. We say *possible;* but, when paper such as that now used in the manufacture of carbon tissue is employed, the thing can scarcely be considered as practicable.

Our reason for here referring to this phase of carbon printing is that a patent has been applied for, the specification of which has just been issued, for a method of obviating the trouble of transferring, and yet secure the image non-reversed by developing on the material which carries the sensitive gelatinous coating.

That the subject may be clearly understood by the uninitiated, we will first of all explain what takes place in carbon printing. The action of light is to render the bichromated gelatine insoluble in warm water in proportion to its action. The longer this is continued, the thicker is the layer that is rendered insoluble. In fact, the image of a finished carbon picture may be said to be built up of different thicknesses of the coloured gelatine. If the light were continued long enough, it would penetrate quite through the gelatinous film to the paper backing, so that it becomes firmly cemented to the insoluble gelatine, from which it cannot afterwards be separated by the warm water.

For some years the carbon process could only be used for line, and not for half-tone subjects. Then, in working, a thin layer of the sensitive gelatine was spread upon paper and exposed to light, until the film was rendered insoluble quite through where it was not protected by the negative. Then, by treatment with warm water, the unaltered portions forming the lights were dissolved away, leaving the others firmly fixed to the paper. Now, it will be understood that if a half-tone subject be similarly dealt with, although the deepest shadows may be fixed to the paper, those portions which represent the half-tones and delicate tints will have a soluble substratum of gelatine intervening between the paper backing and the thin layer made insoluble by the light's action. Consequently, the hot water dissolves this, and, the delicate, insoluble film having nothing to hold it together, the image floats away in pieces.

It was not until the late Mr. Blair and Mr. Burnett conceived the idea that, to obtain carbon pictures in half-tone, the washing away of the unaltered gelatine—the development of the image—must be effected from the opposite side to that exposed to the light, that is, the development must be from the back. Their method was to spread the pigmented gelatine on some transparent or translucent material, such as glass, mica, tracing, or other semi-transparent paper. The exposure was then made through the support, so that, when the print was treated with warm water, a print in half-tone was obtained direct. The drawback to this method was that the grain of the paper, when that material was used, interfered with the delicacy of the image. Talc or mica can only be had in very limited sizes, and glass, on account of its thickness, interferes with the sharpness of the print. Moreover, paper is the material upon which the majority of pictures are required.

Fargier spread the coloured gelatine on glass and exposed, then coated the film with collodion, which served to hold the image together during the development. It was afterwards floated on to paper or other material. Swan's first tissue was made upon collodionised glass, and, when dry, stripped off and exposed with the collodion next the negative. This was afterwards cemented to paper for development.

From the above it will be seen that the first carbon prints in half-tone were all made by a direct process. This method has now, however, been re-discovered. The object of the "invention" is stated to be the avoidance of the transfers. The method proposed is this: Instead of making the tissue on paper, it is to be made on thin sheets of mica, and exposure made through that, precisely as was done by Blair before the invention of Swan's process. Setting aside all questions of the validity of such a patent, if it is sealed, we fail to see what practical advantage there would be in this method of procedure, seeing that sheets of mica sufficiently perfect for photographic purposes can only be obtained a few inches in dimensions.

If it were desirable to produce carbon pictures on a transparent medium, as was done in the early days, with the object of avoiding the transfer operations, then xylonite or celluloid would be the best material to employ. It is cheap, can be had in large sheets of any thickness or thinness; furthermore, if a large demand for it were created—which is more than doubtful, at least, for this purpose—it could probably be supplied in continuous lengths, and then be coated by machinery, as in the case of paper. We just mention this application of xylonite, as it might otherwise some day form the subject of another patent.

PARA-AMIDOPHENOL IN COLD WEATHER.

WE recently called attention to the uncertainty that may arise in cold weather from the partial crystallisation of stock developing solutions, owing to a sudden or abnormal fall of temperature, a danger that is more likely to be experienced with concentrated solutions or those which approach the saturation point of the substance. With ferrous oxalate it has long been known, and more recently it has been found to arise with both hydroquinone and eikonogen; while pyro, from its extreme solubility at all temperatures, is practically free from it. Within the past week we have been warned that it is not improbable that para-amidophenol may cause more trouble in this respect than any of the developers mentioned, owing to its very low degree of solubility, even in the presence of alkali. Two bottles of stock solution of para-amidophenol and the

hydrochlorate, respectively made according to the formulæ given in a leading article a fortnight ago, and containing only three grains of the developing agent to each ounce, as well as a third, made, according to the formula of Dr. Eder, with caustic soda, published a few weeks back, were all found on examination to have deposited a crop of crystals, which, in view of the small quantity of material originally held in solution, might fairly be termed "copious." That the crystals consist mainly of the reducing agent is plain by their form, which differs utterly from that of any of the other ingredients, even if those were present in sufficient quantity to be likely to crystallise out, which they were not, the precipitate consisting of tufts of well-defined plates or prisms. It was noticeable, in the case of the para-amidophenol itself, which forms a brown solution, that the crystals thrown down were colourless, or practically so; whereas, before solution with the sulphite and alkali, they had a very dark colour. In this respect para-amidophenol resembles eikonogen, which, when discoloured, may be restored to its original state by recrystallisation from a solution of sodium sulphite. Those of our readers who may be using the new developer during the present cold weather will do well to keep the solution at a normal temperature.

COPYING POSITIVES.

In this, our concluding article on the topic, we intend to advert to some of the more difficult aspects of the work. From the outset it is understood that what is in view is the best reproduction of a given photograph, and this involves having to be satisfied with work which, on its own merits, is inartistic, though it may afford excellent groundwork for a skilful pencil to make into a presentable picture. Among the most frequent portraits of the class we speak of will be found what are often irreverently termed tintypes—glass positives on thin sheet metal, with a polished black-enamel surface. It is quite possible with such a positive, so under-exposed as to be almost worthless, to get a very fair copy by a plan now to be mentioned, which we have frequently practised, though we do not remember its having been hitherto described. It consists simply in treating the positive with bichloride of mercury in weak solution—say, about one per cent. This will bring into sight details not perceptible to the eye, and a copy can then be obtained which will give more detail than the original showed. The positive, after the operation, will probably have a bluish tint instead of white, but this will be no drawback, if not, indeed, a distinct advantage. But the greatest care must be taken before attempting the operation on an old positive, and an experimental trial on a worthless picture should first be made. The danger is in the film washing away as soon as it is moistened. To prevent such a *contretemps*, the plate must first be soaked for some time in methylated spirit containing ten per cent. of added water, and then gently placed in the dish containing the bichloride solution, which, again, after the whitening is complete, should be most carefully and gently washed out of the film before drying the picture. This is the plan we have always adopted when trying such an experiment, but, we must repeat, it is a risky process. It is possible that ether saturated with water might not affect the collodion, but it would need first to be tried, otherwise it is a good solvent of the bichloride. If the picture to be copied were varnished, we would advise its being left alone; still, if the visible image is so worthless that an attempt with the bichloride might be made, the varnish should be removed by immersing in spirit, which would be safest if diluted with five per cent. of water, and then in a second dish of spirit with five per cent. of ammonia solution added, and again a third similar soaking, followed by plain water. Shellac varnishes are mixable with water when a small quantity of ammonia is added.

Finally, all mercurially whitened positives should be varnished with a benzol varnish, say, for example, ten parts benzol, and one of dammar resin. There will occasionally—often, indeed—be needed copies of positives so over-exposed that the image is almost invisible. These, also, if the exposure be kept down, will copy "better than they look" in the usual way. But there is a better plan by far. This consists in treating the over-done picture as a negative. It is first placed in the usual receptacle for making lantern slides or enlarging negatives, and a transparency on collodion or a dry plate taken from it. It will be a very poor picture indeed that will not produce a transparency which is a startling improvement upon the original. From this transparency a negative may be obtained in any of the ways usually adopted where carbon work is done. Perhaps the simplest way is to take a deep carbon print and develop upon a glass support. The result will be a negative from which a print in every way superior to the original positive, even if enlarged several diameters, may be obtained. It may be observed that, as old glass positives are usually backed with black varnish, it will be necessary to scrape this entirely away before proceeding to make the transparency. But let the operator beware! Sometimes the black varnish is placed upon the collodion side, so that scraping the varnish off would mean destroying the picture.

We have, lastly, to consider paper prints. There is little fresh to say about them, as all photographers are familiar with the vagaries to which they are liable. Some operators prefer an all-round light to fall upon the print when copying, some a top light only, and others, again, a side light only. Any one by taking the same print in three different ways can choose for himself which he thinks the best, and in doing so will gain valuable knowledge.

We will conclude by an account of a very successful copying of a paper print we recently saw executed. A lady sent to a photographer an opal picture to be copied and enlarged, as it was the "best she ever had." She despatched it by post, protected by one piece of stiff cardboard, and put the postage-stamp just over a corner of the plate! The result need not be described, though the face was broken into not more than three fragments. A paper print, from the same negative evidently, was sent, but it was considered not good at all. Our advice was sought as to what was best to do under the circumstances. A very slight inspection showed what ought to be done. The paper print was clearly from the same negative, but exhibited the distortion through expansion in one direction of the wetted print, to as great a degree as we ever saw it; it was almost a caricature. By our advice the print was placed in a slanting direction for copying, instead of at right angles to the optical axis, so that the breadth would be reduced. Next, a swing-back camera was used, so that the focus could be accurately adjusted though the picture was not equidistant in all its parts from the lens, this same adjustment also tending still further to reduce the breadth. The resulting photograph was excellent, and we had the satisfaction of learning it greatly pleased the lady for whom it was executed. In conclusion, we hope that our excursus into one of the bye-ways of photo-

graphic operations may not be without both interest and instruction to many who have to undertake what is usually looked upon as a species of hard labour.

Mr. Bolas's Lecture.—The attendance at the first of the three lectures arranged by the Photographic Society of Great Britain was not so large as the well-wishers of the scheme must have hoped for, the number present being, we believe, under thirty. This is the more inexplicable and regrettable, since it is pretty generally known that Mr. Thomas Bolas, whether talking or writing, can always be followed with instructive results. The *Relations of Photography to the Industrial Arts* is a peculiarly appropriate theme in view of the Society's attitude towards the suggested technical institute. Mr. Bolas's ideas for securing facilities for the pursuit of experimental work to be furnished by the State were of a practical and cogent nature, and the further plea for the establishment of means for informing the manufacturer and commercialist as to what had been attempted or accomplished experimentally in any given direction is most happy in its originality and appositeness. By the way, in our report of the lecture the title is slightly wrong, the word "applications" should read "relations."

The New Methylated Spirit.—A correspondent of the *Chemical News* suggests that as the Revenue authorities have no object in view save the prevention of drinking alcohol, which has been allowed to pass duty free, they ought to be ready to allow the spirit to be sold to all persons who are ready to enter their names in a book kept by the retailer and open to inspection by the authorities. As an alternative, he suggests the issue of licences at a nominal charge. Both suggestions are reasonable, and conceived in the proper spirit of compromise. We again ask, When are the photographic societies going to stir in the matter?

Retirement of Mr. Glaisher.—At the meeting of the Photographic Society of Great Britain on Tuesday night, the Chairman (Mr. J. Spiller) announced that the President, Mr. Glaisher, had definitely decided not to allow himself to be nominated for office at the approaching anniversary meeting. Mr. Glaisher's retirement will mark the close of an official connexion with the Society of long duration and immense usefulness, and we are confident that in thus terminating his tenure of the Presidential chair he will be the recipient of wide and sincere regrets, accompanied by no less cordial thanks for the great services he has rendered the Society, and through it photography in general.

Photographic Society's Dinner.—It has been decided to hold a dinner of the Society on February 8, and the arrangements for it have been taken in hand by Mr. William England, than whom nobody is better fitted for such a duty. It is understood that on this occasion Mr. Glaisher, the retiring President, will occupy the chair, and, as this is the last time that he will be present with the Society in his official capacity, it will be a graceful act on the part of all members to endeavour to put in an appearance at the dinner. We therefore hope that this dinner will be made the occasion of a large attendance, and that the President will carry away with him the recollection of the warmest possible demonstrations of esteem from a goodly gathering of members and friends.

Support for the Society.—The earliest practical outcome of the affiliation scheme was shown at the last meeting of the London and Provincial Photographic Association. On that occasion Mr. P. H. Newman, at the conclusion of his lecture, touched upon some of the incidents in connexion with the late exhibition. This gave rise to a brief but animated discussion, and culminated in the passage, without dissent, of a resolution commending the action of the Society's officers in the late crisis. We are sure that the spontaneous support of the affiliated societies will do much to strengthen the hands of the parent Society in future.

"Honours" for Photographers.—Two or three "societies," founded for the encouragement of literature, science, and art, are at present touting for members in a manner not usually adopted by reputable representative bodies. They send you a high-flown communication, informing you of your election, and asking for your subscription; and, if this brings no response, they write other letters in the "name of the council," asking for the honour of adding your name to the roll of the society, and so forth. These so-called "societies" have for months past made photographers the objects of their particular attentions, and several of their circulars have reached us. We hope none of our friends have been rash enough to part with any subscriptions or promises of support to societies which anybody can see with half an eye are merely well-disguised commercial speculations.

Dr. Emerson.—Since his famous "renunciation" of last year, Dr. P. H. Emerson, the apostle of naturalistic photography, has disappeared from view. This disappearance, however, has served to bring out the Doctor's talents in another direction, as we gather from the book reviews that he has been very successful in a collection of "East Coast Yarns," published by Sampson Low & Co. This, perhaps, answers the question that has so frequently been asked of late, "What has become of Dr. Emerson?"

The "Daily Chronicle" Again.—The erudite gentleman who is responsible for the "Science Notes" in the Wednesday issues of the *Daily Chronicle* says that "a communication by Herr Waterhouse in Eder's *Jahrbuch* announces that positive photographs can be obtained direct from the camera by adding small quantities of a substituted sulpho-urea to the developer,' &c., &c. We humbly submit that science for the masses should be clearly written, and at least correctly expressed. Colonel Waterhouse's experiments were first published in these pages eighteen months ago. The *Daily Chronicle* is rapidly acquiring an unenviable reputation, not only for inaccurate, but for late news.

Large Cameras.—Mr. P. Meagher has recently completed a fine 22 × 22 in. brass-bound camera for the King of Siam. With a cone attachment, it has a focal length of twenty-two feet, for copying purposes. We are pleased to find such evidences of prosperity in the camera-making industry, conjoined to the recognition of the high merits of British products. We also learn that Messrs. Platt & Witte, of Kingsland, have recently completed a camera, to take plates 30 × 30, extending eight feet, which had four special-made screws, two of them being seven feet long. The bellows took fifteen of the largest skins of leather that could be bought, and when completed the camera weighed about four cwt.

THE ORIGINATOR OF THE GELATINO-BROMIDE PROCESS.

A FRIEND has just called my attention to a dreadful outbreak of "Peckhamism" in the pages of one of your contemporaries, and has placed me in possession of the correspondence that has been going on on the subject for some weeks past. It seems that Mr. J. Burgess, assisted by a few friends, anonymous and otherwise unknown, is once more attempting to show that he, and he alone, is the great pioneer of gelatine photography, the inference being that he, and not Dr. Maddox, should be the recipient of the "coming-of-age" testimonial. I say again, because some ten or eleven years ago he made the same attempt, and used pretty much the same arguments; but on this occasion the fight is being carried on with greater vigour and more virulence.

As one of the earliest experimenters with gelatino-bromide, and well acquainted with its early history as well as with the various individuals concerned in its development, and, moreover, having had special opportunities of knowing the facts of the case, I may perhaps be allowed to say a few words in order to put the matter in a proper

light before the numerous users of gelatine plates whose recollection of photography does not date back to 1871.

In the first place, it is attempted to make capital out of the fact that gelatine emulsions had frequently been mentioned before 1871, and that therefore Dr. Maddox has no claim to any more than passing mention as a casual experimentalist—if, indeed, as much. The same argument holds good, of course, against Burgess; but his friends do not say so. Dr. Maddox never claimed, nor has it ever been claimed for him, that he was the originator of the idea of gelatine emulsion; on the contrary, in his first publication he expressly said it was not new. But what is claimed for him is that he was the first to publish a practical and workable formula—not perfect by far, it is true—and to show results produced by it. For the very earliest mention of gelatine emulsions we should have to go back to pre-collodion days, for Bingham, in his work on photography, published previous to 1850, mentions gelatine as one of the possible vehicles in which to suspend the sensitive salts. Le Gray and Scott Archer both, if I remember rightly, attempted to utilise it, and, later, Gaudin and others; but none of them gave any definite formula. In 1865 Palmer patented a gelatino-chloride emulsion for printing purposes; but nothing much was ever heard of that, and it remained for Dr. Maddox to strike the real keynote.

It is said that Maddox's process or formula was not for negatives, but merely for printing upon paper, and required some minutes' exposure in the printing frame. This is a mis-statement that is as culpable in its recklessness as if it were deliberate. In his first notes communicated to Mr. Taylor, Dr. Maddox certainly does speak of paper, though the fact of negatives having been exhibited at the Inventions Exhibition—a fact known to Burgess and his friends—clearly proves the falsity of the statement.

However, the existence of those negatives proves nothing to the supporters of Burgess, for one of them would like to know "where the negatives exhibited on behalf of Dr. Maddox, and for which he was awarded a medal, came from," and opines that the jury who awarded that medal had been greatly misinformed as to the facts. I pass over the imputation this involves, for I am fortunately able to prove the authenticity of those negatives beyond a doubt. In 1880, while the previous correspondence on the subject was proceeding, Dr. Maddox happened to remark to me in the editorial office, at York-street, that some of his original negatives had been left there with Mr. Taylor; as there was a considerable accumulation of such things on the shelves, I proposed a search, and it was not long before we came upon two or three quarter-plate negatives bearing the particulars and *date, September*, 1871, *in Dr. Maddox's handwriting*. There could be little doubt as to their genuineness under those circumstances, and, after lying *perdus* there for nine years, they served to prove in a most emphatic manner that Maddox's process *was* a negative process, and capable of giving results of a very satisfactory character. Those negatives, with, I believe, some others that Dr. Maddox subsequently found, he having been absent from England for some years, formed the exhibit for which the medal was awarded.

The suggestion that the jury had been misled comes singularly unfortunately for the Burgess's side. At least, three of the members had been closely identified with gelatine emulsion as practical experimentalists from the first and through every stage of its progress, and were not likely to have to go far for information as to its history. With the exception of two, the rest of the jury were all old members of the Council of the Photographic Society, and as such were fully cognisant of all that had passed in connexion with the subject. And yet that jury awarded a gold medal to Dr. Maddox without dreaming of Burgess.

And now let us consider what Mr. Burgess himself has done in contradistinction to what he claims. "In 1873 an emulsion was put into the market quite perfect, and for ordinary purposes as good as any made now." "Burgess made an original discovery by going on lines never tried before. He washed the sensitive jelly instead of the plates . . . ." Such are some of the claims. Well, in 1873 I had the pleasure (?) of trying some of the emulsion, or rather the disappointment of not being able to try it. It was so "perfect" that it would not stand the journey between Peckham and Liverpool; in other words, it was decomposed within a few hours of being sent out. Set this against all the talk about the worthlessness of Dr. Maddox's formula! Then turn to the "original discovery," washing the sensitive jelly. Burgess never claimed to have done anything of the sort until seven years after he first tried to sell his emulsion; indeed, it was not until 1880 that he made a single statement with regard to his method, and at that time, it is needless to say, every one knew how to wash an emulsion.

Absolutely all that he had published up to then consisted of advertisements of his emulsion, which he soon had to drop, then his plates, together with an offer to impart the secret of his process to 500 subscribers of one guinea each. He did not even speak of it as gelatine, but left the purchasers to find out what it was as well as how to use it. After finding the emulsion would not sell because it would not keep, he tried plate-making, and, surely, if he were the great "discoverer," who has taught everybody all they know of gelatine emulsion, one would have imagined that he was in a fair way to fortune. But not so. With the greatest thing that has ever cropped up in photography within his fingers, he let it slip his grasp, apparently from sheer want of knowledge of how to work it. He had Dr. Maddox's idea, but failed to carry it out.

In the course of the present discussion, and previously in 1880, the most extraordinary statement has been made and repeated, that Mr. Kennett learnt from him his process, and then went to the patent office, and took out a patent. This is Mr. Burgess's direct statement, not a mere insinuation. Mr. Kennett, the late Mr. le Neve Foster, and "some venerable clergyman" (in all probability the late Rev. J. G. Cowan, a great friend of Mr. Foster's) were at his house one day, and he showed them his process, and Mr. Kennett afterwards took out a patent for it. It is not a very likely story, nor does it reflect much credit on his wisdom as a commercial man to be so ready to divulge his secrets to any and everybody. I think Mr. Kennett would have had to possess a "stronger" conscience than I even gave him credit for to have gone off and patented another man's idea, with the full knowledge that two of his friends, both honourable gentlemen, were aware of his dishonesty.

But Mr. Kennett's version of matters is slightly different. He had been experimenting with gelatine emulsion off and on for some years, and had got his process into workable form, but held it back, doubting if there would be market enough for it to recoup him for the necessary outlay in starting it commercially. When Burgess's emulsion was advertised he wrote for a sample, stating that he had been experimenting in the same direction, and subsequently went to see Burgess on his invitation. He found the latter in trouble with his emulsion, and about to start plate-making, and, apparently, altogether at sea. If I remember rightly—for I am going on the recollection of a conversation of ten or eleven years ago—there was a suggestion on Burgess's part that they should work together; but, apparently, Kennett did not think it "good enough." The attention that attempted introduction of the new emulsion had attracted showed him there was an opening for it, and he then took out his patent.

Kennett's patent, by the way, was solely for the drying of the sensitive emulsion, to enable it to be kept, and, in spite of the patent—surreptitiously taken—Burgess made no claim to its being his until 1880, seven years later, a most extraordinary *lapsus* on the part of one who then and now claims so much.

Not succeeding at making plates, in the latter part of 1873 Burgess sold his process, such as it was, to Mr. Mawdsley, of the Liverpool Dry Plate Company, but I do not think he ever succeeded in doing anything with it. He certainly advertised gelatine plates in the ALMANAC for 1874, but had scarcely time to try the process before the work went to press, and the advertisement did not reappear the following year, nor, indeed, did Mawdsley go in for gelatine plates until after the publication of Bennett's method in 1878. Surely, again, if a practical man like Mawdsley could do nothing with the process, it was not worth much.

Finally, in 1880, Mr. Burgess became connected with Messrs. W. T. Morgan & Co. in the introduction of gelatino-bromide paper, and wrote a pamphlet for them. But they soon severed the connexion, and then it was that Burgess commenced to put forward his extraordinary claims. Then, as now, the arrogant and insulting tone in which he alluded to Dr. Maddox, and every one who had anything to do with gelatine, went far to alienate from him any sympathy that

might have been felt for him as an unsuccessful "inventor," and then, as now, I felt compelled to point out the fallacy of his claims.

Though my own experience with the emulsion was unfortunate, I am quite willing to, and do believe, that some of the emulsion and plates he issued were of good quality, for otherwise they could not have secured the notice they did. But to put himself forward as the "originator"—his own word—of gelatino-bromide, when he came just two years after the publication of Dr. Maddox's formula, is preposterous. To pose as a benefactor to photography when he never published one atom of information, and failed even to benefit himself, or as an ill-used individual because Dr. Maddox, and not he, is to get a testimonial is supremely ridiculous, and it is surprising that any one with the facts within reach, and well up in the literature of the subject, should be found to abet him.

W. B. Bolton.

AMERICAN NOTES AND NEWS.

Printing-out Platinotype.—One of our American contemporaries having suggested that the platinotype patents in America were on the point of expiration, Mr. Alfred Clements writes to *Anthony's Bulletin* to correct the misleading statement. Incidentally he makes the interesting announcement that a printing-out process in platinum has long been in the mind of Mr. Willis, and that hundreds of experiments have been made by him in that direction, but the many difficulties in the way make it almost impossible to ever get a perfect process of this kind. We are sorry to hear this. An indefatigable experimentalist like Mr. Willis would, we should have thought, have been able to equal the efforts of our Continental rivals, if not surpass them. Mr. Clements is surely not ignorant of the fact that printing-out platinum papers have long been in use.

Interesting to Lanternists.—Discussing the recent lantern explosions, *Anthony* points out that in the case of a bag the explosive force is exerted in all directions, whereas, in the case of a cylinder, there is seldom more damage done than the blowing out of the gauge or plug, as happened in London a short time since. Mr. F. A. Bridge will be glad to know that "in this instance, too, the accident was wholly due to the carelessness of the operator, who opened the valve suddenly, and allowed the full pressure of the stored gas to accumulate in the pressure gauge at once." This is hardly correct. On the occasion referred to something else besides the destruction of the gauge took place, and, according to expert testimony, the cause of the accident was not that above assigned for it.

Photographing Chinese Immigrants.—America, by which we mean the United States, is a free country, but the authorities there will not permit free entry into that country of every one so disposed. Amongst others, the Chinese are debarred admission, except under certain restrictions. The word has been passed that at the ports of entry into the States from Canada photographs shall be taken of all Chinamen arrested for unlawful entry into the United States, for subsequent identification of those who return after having been deported to Canada.

Large Panoramic Pictures.—At a recent meeting of the Society of Amateur Photographers of New York, two panoramic pictures taken upon Carbutt flexible films were exhibited. They were made on colour-sensitive films with a Ross lens of fifteen inches focus in a Moessard panoramic camera. The length of each picture was forty-eight inches, and Mr. Carbutt hoped soon to get a film of larger size, some seventy-five inches, or even longer. The angle included was said to be 165°. The pictures were perfectly sharp, being made with the lens working at *f*-64.

Camerists versus Photographers.—We learn from a New York daily, the *Times*, that the term "camerists" as applied to amateur photographers to distinguish them from the professionals, has apparently, to use a familiar expression, "caught on." For a long time the amateurs felt that some name should be adopted which would be appropriate and suggestive of the art as well as clearly separating them from the professionals. The word "photographer" invariably brought to mind the man who, after fussing for fifteen minutes behind a curious-looking instrument shrouded in a black cloth, would cry out, "Now, look pleasant," and then, watch in hand, would keep the sitter in a state of mental distraction for what seemed several minutes, and then, perhaps, remove the plate-holder and retire to his closet, without even telling the sitter that the terrible ordeal was over, and that he could resume his normal cast of countenance if he chose.

English versus American Plates.—Mr. Francis B. Troup, who is, we presume, an American amateur, writes to the *Photographic Times* to complain that during a residence in the dampest corner of England (wherever that may be) all his plates were so affected by the damp that they were useless for securing good negatives. So far so good. "But mark," he says, "my experience with American plates." Here he goes on to say that he imported some of Mr. Carbutt's plates. These were sent to him specially packed for the sea voyage, of course, but he accidentally left a box in his dark room for a month during the rainiest weather he ever experienced in England. He tried them against an English brand which had also been in the room for a month, with the result that the Carbutt plates were excellent, and the others not worth printing. "It was a severe test, but the plucky Americans stood it so well," &c., &c. If this means anything at all, it is that an American gelatine plate is impervious to the effects of damp, and that an English plate is not. Fiddlesticks, Mr. Troup!

The late W. Notman.—From *Wilson's Photographic Magazine* we learn that the death of William Notman, of Montreal, recorded in our last "American Notes," was more sudden than we were aware of. Only ten days before his death he was in New York in apparent good health, forming plans for photographing at the coming World's Fair at Chicago. Mr. Notman, says our contemporary, was one of the first artists in our profession. Being an educated painter first, he was always able to produce work of the highest photographic character, and to win fame and fortune. He was a leader in style as well as in art, and conducted successfully many great enterprises, among which was the long line of remarkable panoramic views of the Canadian Pacific Railway. His death is a loss to us all.

Pictorial Criticism.—A feature in connexion with criticism not known, or not, at any rate, yet practised in this country, has been adopted in *Wilson's Magazine*. A picture is published, and the criticisms of the readers on it are invited. The one which is now "on" is entitled, *By the Still Waters*, and opinions on its composition, treatment, and general merits are freely given by brother artists. As might be supposed, they are somewhat conflicting. The idea strikes us as being a good one.

Solution of Celluloid.—A contemporary says that solution of celluloid may readily be prepared that will prove useful for coating trays or other dishes, and that will resist the action of acids and alkalies, by taking spoiled celluloid films, and, after removing the emulsion, dissolving them in fifty times their bulk of amyl acetate. The celluloid solution serves admirably as a varnish for negatives.

A Large Portrait.—The portrait of the delightful Irish, *not* American, actress, Miss Ada Rehan, which hangs in the *foyer* of Daly's Theatre, New York, is said to be the largest photograph in the world, measuring about $7 \times 3\frac{1}{2}$ feet. It depicts the lady in her impersonation of "Rosalind," and is the work of M. Walery, of London.

Photography at the World's Fair.—The Christmas number of the *Photographic Times* deserves special notice. It contains a pictorial frontispiece, and three other pages of illustrations; the initial letters of the articles are printed in red, and appended to each article is not only the signature, but a neat little woodcut of several of the writers. From it we learn, on the authority of Mr. Gentile, the probable Superintendent of the Photographic Department

of the World's Columbian Exposition at Chicago, that photography is not to have a building devoted entirely to it at the World's Fair, but will be classed under the department of Liberal Arts.

SOME RECENT EXHIBITIONS.

[A Paper read before the London and Provincial Photographic Association.]

I SUPPOSE it is anticipated by most sanguine persons that the exhibitions of photographs which take place annually should indicate a steady advance in some directions by the numerous branches of that seductive and scientific art, and I trust that the sanguine people have not been disappointed this year which we have just undergone. I cannot individually say enjoyed, because I regret to admit that the weather and the "crops" of photographs alike last season did not come up to my expectations, though I am not a sanguine person. One reason, of course, may be—and I am more than willing to admit it—that I belong to that very small body of critics who do not know everything about photography; and, while I regret this exceedingly, and am duly ashamed, I am sensible that, were I better informed, I should be able to dwell upon and enlarge for your behoof this evening on some new process or paper, methods of printing, toning, developing, perspective, or para-amidophenol fad, which counterbalanced and entirely outweighed any general shortcomings in the recent exhibitions that might be expected to have vexed our righteous souls; but, alas! these lights are denied me, and when it was suggested to me to say something to-night to you, and to take the recent exhibitions as a topic, I had almost replied with the monosyllable "No;" but I fortunately remembered in time that no member of your Society could take a negative that would not print, and so I consented to say something about the exhibitions; and if, in this case, *Nil nisi bonum* will scarcely apply, at least we will see if we cannot get some good out of them. Now, there are those among that limited class who do not know everything, and of whom we have been thinking—some who rejoice, and would even make a virtue of their ignorance, especially on the question, if it were put to them emphatically, of what on earth was the reason some of the exhibitions existed for at all, and what, in the name of fate or fatuity, some of the exhibitors had to exhibit? These questions are at once so startling and so shocking that they, doubtless, deserve to remain unanswered; but, yet, we must not ungenerously leave the aforesaid limited class in its ignorance; and so, with your permission, we will advise them to reply to the pessimistic and blatant questioners that their questions are offensive to the professors of a wisdom that recognises that there are and will be, for a year or two to come, more things in heaven and earth than all philosophies are equal to, and, moreover, regret that the said questioners are probably as lamentably obtuse to the universal fitness or "cuteness" of things in general, as they are to the disguised blessings of photographic exhibitions in particular.

"And wish them not reply,
For thou must give the lie."

or, if we would not be quite so rude as the ancient and pessimistic poet, suggest that their ungrateful fuming and foaming be quieted by pointing out that there is an end of all things, even to a tether, for, when a tether is at its full length, and stretched to the uttermost, it breaks. Now, it is quite obvious that the length of tether already arrived at by some sublunary institutions—I am afraid I cannot include the weather—but say, for example, the School Board and some photographic exhibitions, the tension is such that fracture must be imminent, when will come the relief we, as well as our impatient or ignorant friends, so much desire.

I did not see many exhibitions last year, so perhaps my sufferings are despised by those who saw more than myself: but suffering is a relative question, and mine were severe enough; yet I will attempt, if strength serve me, to cull the flower health from the upas disease—to slightly paraphrase the bard—and thus, at least, escape your objurgation, if not gain your thanks. Seeing what a task is before me, yet feeling that the case is not hopeless, I, relying on your just consideration, say at once, Come, then, let us reason together.

I venture to premise that, even in these pattern-making days, there are bad years and good years in most things, besides the weather or the crops, and, in support of this assertion, should doubt arise, I will admit that I have known a year (but this is a secret, and only to be whispered in the strictest confidence), a year, I say, when the exhibition of the Royal——oh! ah! I see, you guess: well, when you know, it must be allowed that it was just a trifle below the average. Indeed, I believe, in connexion with annuals (I should have said *eternals*), that more than one of the reputable old classics nod sometimes, and I would, in this same connexion, ask you, Shall we grudge the forty, or even fifty, winks now and again to those who have done so much to amuse, edify, or even astonish us, and disallow a similar somnolent licence to exhibitions that are neither Royal nor Academic? But I think I hear you saying you have been a judge, and you are now talking like counsel for the defence, or a special pleader. Well, perhaps you are right, and all I can reply is, a judge is not of much account if he cannot see both sides of the case; and this last year I have seen the ins and outs of so many cases—in fact, turned them inside out, so to speak—and there is one special case I may mention, part heard *in camera*, and in which I am rather glad I have had nothing to do with the ruling. This, you are aware, was a police case, and I am sure we must all rejoice that it has been settled out of court.

I think it is now high time we began to consider the relative merits of some of the exhibitions, and what their value may be to both the professional and amateur photographer, and how, if possible, that value may be improved.

Firstly, photographic exhibitions, if not unmixed blessings, as we partly suspect, are, in the present condition of the art, greater necessities than ever, especially so if the amateur is to be recognised; and as he or she, like another class "is always with us," the amateur will be recognised. I think it is expedient also that he should be medalled, for, after all that can be urged, it has never seemed to me that the professional photographer has really much cause of objection to the amateur, because not only does he tend to popularise photography by his efforts, but his very failures increase the popularity and appreciation of really good photographs, and thus adds to the chances of the professional, who, in the long run, and having the start of the amateur, must, in the nature of things, generally beat him badly. Moreover, it is from the ranks of the amateurs—diligent, absorbed, and therefore most successful amateurs—that the ranks of the professionals are best filled. Now, granted that the necessity, and even virtues, of the amateur are recognised, it is desirable that by exhibitions, medals, and competitions, the amateur should gradually learn what he is made of, and how far he falls short of a high standard of excellence.

But here, I must admit, we are met by the great and principal difficulty, for while, on the one hand, it is obviously desirable to encourage the amateur by allowing him the indulgence in the pardonable human weakness, a little vain glory, dear alike to himself and his appreciative relatives—no inconsiderable public, by the way—it is equally necessary not to give false impressions of perfection in his performances, that a too indiscriminate awarding of prizes and medals must foster. I have seen something too much of this last year, and must not neglect an opportunity of dwelling upon it.

While saying that I think photographic exhibitions are greater necessities than ever, I am distinctly of opinion that we are having rather too many of them, similarly that we have too many exhibitions of paintings for the real benefit of art. The output may be great, but the quality has to be considered, and this often suffers, I find, in the ratio of the output when it exceeds reasonable limits.

We have two very important exhibitions of photographs annually, practically in London—I mean in Pall Mall and the Crystal Palace—and it is to these two exhibitions I propose now to confine my remarks, as to my mind they are more than extensive enough to absord all the good work of the year. I mean, of course, by this all the work that is worthy a place in an exhibition that puts itself on competitive terms with the best photography in the world.

The Crystal Palace Exhibition last year, I have been solemnly assured in some high places, was "below the average." I am very glad to hear it, as it speaks very hopefully of photography, and I do not regret in the least the suffering I endured on that ever-to-be-remembered head-splitting day on which I was allowed the privilege of being a judge of so much high-class work—work, I should observe, that was placed equally to the advantage of itself, the exhibition generally, and the judges. It might be a pleasure, instead of an agony, to judge such a collection of photographs if the Crystal Palace authorities would only let us see the exhibition at some time when the public were not present; but as it is, it is an infliction of such inconceivable torture to those who have not experienced it, that I have no hesitation in saying that, should I ever be honoured by being asked to be a juror again at the Crystal Palace, I should much prefer to fulfil the office on a Sunday, when any conscientious qualms or scruples would be more than set aside by the knowledge that, in attending on that day, I was participating in an act of mercy to my co-jurors. Comparisons are notoriously odious, nevertheless they must be made sometimes, and I must say that, in spite of the physical objections to being a juror at the Crystal Palace, where one is bewildered by the incessant crowd, and choked by the insidious dust, it is a far pleasanter task to do the actual judging at Sydenham than at the

exhibition in Pall Mall; and the reason of this is the principal reason for my inflicting on you this address to-night, and drawing your attention to what I conceive as an important consideration. It is not the question of the photographs themselves, although I shall have more to say on that subject presently, so much as the arrangements at the respective exhibitions.

I may be answered, "But see the space at command at the Crystal Palace." Well and good; I will attend to that also presently. But, now, at the Pall Mall Exhibition, in the years that I have seen it, it has been difficult to find any arrangement at all. This year, at least, I am confident there was none worth mentioning. A juror entering, for the first time, the exhibition room of the Photographic Society of Great Britain will naturally say to himself, "This is, or should be, by its traditions, the most important exhibition in the country;" and, if he has any honesty, as it is usual to suppose a juror may have, he will endeavour to fix in his own mind a certain definite standard of excellence before he goes to the question of awards. He may, if it be conceded that he is honest, have some allowable misgivings on the point of excellence, and he may not unnaturally turn to the works and seek in the places of honour—supposedly the centres of some of the walls—for guidance by what the hangers may have considered worthy of this distinction. Now, I have no hesitation in saying that last year, in an important class of work, the juror so doing would have been more at sea than ever. (I will spare both pictures and names, making no invidious references; but those who saw that exhibition, and remember the localities of the various works, must, I think, bear one out that a system that might be supposed to lead to the finding of excellence in certain places, was "more honoured in the breach than in the observance."

A querist, addressing himself to the officials for explanation, was met by the inevitable reply, 'Well, you see, the handsome framing has a good deal to do with the arrangement.' Of course, in what I have stated I am not including one conspicuous, not to say notorious, series of photographs which should have been judged *sui generis*, and to which I shall have to allude subsequently. So that one finds that the most important consideration of the most important photographic exhibition in the country is the consideration of handsome framing. I frankly admit that one's heart sinks within one at the contemplation of such a state of things in London at this time. Such, however, was my experience; and, coupled with your own observations of the exhibition, which can scarcely be favourable, I think I am justified in pressing on the attention of this important photographic society, known widely as it is as the London and Provincial, to see if some steps cannot be taken to prevent, if possible, a recurrence of a system of hanging which cannot do other than injuriously affect the whole of your profession. Such a system of hanging, in conjunction with the permission of monstrous and ridiculous framing, as we have witnessed this last year in Pall Mall, can scarcely be conceived to have arisen from ignorance, and yet it seems more serious still to attribute the cause to a *laissez-faire* indolence in the leading society of Great Britain. However, thus is forced upon one the comparison with the Crystal Palace Exhibition, which, with all its drawbacks, has an admirable arrangement of getting the exhibits into groups in sheltered bays, a system undoubtedly necessitated by the natural conditions at the Crystal Palace, but which, I submit, is absolutely necessary anywhere for the due enjoyment or criticism of small works, such as photographs. I do not suppose that the Pall Mall folks would entertain the idea of such a system for a moment, but probably say that it was not possible in their room. I am, however, not so sure of this, and, if attempted, the sides of the bays might be so hinged as to set forward to a stop for the convenience of the lantern shows in the evenings without disturbing the frames in the least degree. I argue that such a system of top-lighted bays allows of adequate classification, allows a better display of each exhibit, giving more room than at present, and permits that concentration on individual work which I insist is absolutely necessary to its enjoyment or criticism, and which is quite impossible with the distracting influences of a large wall.

If it be advanced that such an arrangement as I have described cuts up the room, detracting from its general effect, I answer this is immaterial. You can make no large room look well by covering its walls to seven or eight feet high with a mixed collection of photographs, however mounted and however hung; even supposing the room were so spoiled in general effect, this, I again contend, is of no consequence to the main purposes of the exhibition. Furthermore, I am of opinion that the exhibition being at present quite large enough in point of numbers, the arrangement I propose would allow of the photographs being adequately mounted, which cannot be the case under present conditions. We all know that small works of art of any kind gain immensely by a good width of margin, as it assists the riveting of the attention, the enjoyment being proportionate in the same degree as lantern exhibitions, which are not a little dependent for their success on this condition of the isolation of the picture, and consequent consecration of our attention.* One lesson is distinctly derivable from these two exhibitions, and I hope that I may be able to impress it as forcibly on this society as I feel it myself—it is the anomalous position which portrait and figure photography continues to occupy. I am aware that my point of view has been a matter of consideration, and has even caused dispute over and over again; still I find matters remain very nearly as they were, at least as to the question of judgments or awards, and I would once more ask, What is to be the decision on the subject of retouching?—for it is really important. One looks at a good portrait or series of portraits, and expresses genuine admiration for pose, light, and shade, besides other artistic qualities, yet your better technically informed co-juror smiles, and at once says, "Ah! yes; but you know half of it is retouching." Fatal word, and dreadfully cold water to be douched with so constantly, calculated to discourage the hope for ever of any advance in photographic portraiture; but what is the result? You are obliged to give some medals, and what do you give them for? I venture to say, that it frequently happens nobody knows but the lucky photographer, who, as often as not, laughs in his sleeve. If the work of portraiture is to be judged on its photographic merits, plus excellence of subject and pose, it is time the judges were allowed an inspection of the negative. If this is not thought to be desirable or convenient, surely there can be no objection to sending with every work of the kind for competition a first proof before retouching or even spotting has been attempted; this proof not necessarily for exhibition, but for the use of the judges. Nothing, at any rate, can be more unsatisfactory than the present state of the case, which demands some better means of criticism being in the hands of the judges for them to be either consistent, or, with their best endeavours, fair. Of course, it would be a most desirable thing if, in all cases, photographs of a head could be obtained without retouching; but, although this may be possible in some limited instances, I fear that with certain types—female especially—that even in these days of orthochromatic plates, and granting—which is very unlikely—the protracted exposure incidental to the use of the yellow-glass screen, the desideratum will hardly be attained. I cannot help thinking it would be wiser to recognise retouching as a necessity than to burke its consideration, or wink at it, as is the undecided plan at present adopted.

One thing is certain, commercial portraiture is, and probably must remain, impossible without retouching, and if it were recognised as an art, as its importance demands, it would be far more likely to be confined to artistic limits, as we see in such rare instances, than transgressing all rules of sobriety and taste, as is so frequently manifest. I have little to say about individual works in these two exhibitions; they spoke for themselves, and the judges were quite content to stand or fall by the justice of their awards. I am, doubtless, expected to say something specially on the art question. My remarks, however, must be very brief, and while expressing any satisfaction at some notable examples of artistic feeling in both exhibitions, as regards composition in line, and light, and shade, I recognise no advance, so to speak, all along the line; those who have the artistic feeling always show it, though some of the well-known names do not come up to the standards they set themselves in former years. The efforts of those who have not the artistic feeling, however laudable in some cases those efforts may be, they are sometimes none the less painful, and it was with considerable surprise to me that works of this class were so observable in Pall Mall.

It is not given to every, in other respects, excellent photographer, to be essentially artistic, and we ought to feel glad that there are obvious fields of occupation involving considerable interest and enjoyment in utilitarian and archæological directions for, I will not say the "weaker brethren," for they are strong in their several qualifications and gifts, and set a good example to the amateur, who may not have the art afflatus, by doing something useful, doing it well, and consequently benefiting the art of photography generally.

And now, before I conclude, I should like to say a word or two on the standpoint of criticism. I do not, myself, see the absolute necessity of judging every photograph that comes before one as one would judge a pictorial composition. There are, of course, those who set out to make pictorial compositions—these should, and must, be judged by the severest tests; but there are many excellent photographs in all exhibitions which, if I may so speak, are absolutely innocent of any such idea or intention, photographs which pretend to be no other

* It becomes a serious question for the members of the Photographic Society of Great Britain to consider whether, in case their present room is unsuitable for such arrangements as I venture to propose, in justice to themselves and their art, they should not seek another place for their annual exhibition.

than more or less faithful memoranda of places and things. Modern criticism, I fear, is rather prone to scoff at these things, and unadvisedly, for they have their value. I am not holding a brief now for the inartistic; I have no such idea. I think you know that from what I have said here and elsewhere, I love and revere the artistic as I scorn and despise pot-shotting or those who would tell me that a photograph of nature must of necessity be a work of art; but I do say this, that a simple photograph that makes no pretention to being a work of art, should be judged on its own unpretending merits and standpoint; if it cannot be a thing of beauty, it may at least be a thing of use. There are heaps and heaps of studies that are of special value in this direction, not at all to be included in that incongruous and vague, if art-affecting term, "bits," in its generally accepted sense, but bits of utility that the painstaking amateur may make exceedingly useful to the artist.

But back to the exhibitions for my last word, and it is to tell you what, perhaps, you already know, but that I, as one of the judges in Pall Mall last year, far from holding as a secret, think cannot be published too widely, viz., in our report on the exhibition to the Society a rider was appended. Proposed originally by myself, it had the honour of adoption in a very slightly modified form by my co-jurors, the general sense being to this effect, that we regretted to find it necessary to suggest to the hangers in future greater discretion in the exhibition of works, as we found many on the walls unworthy of a place in the Exhibition of the Photographic Society of Great Britain. I may now add that they were inferior works to many I saw last year in amateur competitions.

I am perfectly well aware that I am on delicate ground in the matters I am discussing, but I make no excuse for telling tales out of school, if any one pleases to call it such. "The chiel amang them" in Pall Mall is neither ashamed of taking notes nor of publishing them, and, indeed, considers himself more than justified by the important, nay, I may say national, considerations involved. A defence is quite likely to be set up, if any notice is taken of my remarks at all, that the exhibition was injured by the withdrawal of certain works after they were hung. But whose fault was that? Not that of the public, surely, who are, or should be, the chief consideration. While I freely admit that the exhibitor who withdrew those works on his section would well have afforded to have allowed them to remain, though ineligible for competition from infringement of established rules; yet the works had no business to have been hung at all, if they had transgressed those rules, but, being hung, nothing could justify their being taken down after being exposed for hours to the consideration of the judges, and withdrawn, so to speak, from under their very noses, almost at the moment of making their awards.

I am aware that in making this statement I am in direct conflict with the impression conveyed by the assistant secretary as reported in the public prints; nevertheless, what I say is perfectly accurate and literally true, while the impression conveyed by the assistant secretary is entirely misleading, for though we, the judges, did not make out our report, of course, until the evening was well advanced, having to inspect the exhibition of lantern slides, yet we had registered many awards at the time Mr. Davison's works were withdrawn. We had had several hours to look at them singly and at our leisure; moreover, as I have stated, we were absolutely approaching these photographs in the afternoon in a body, to decide upon them, when they were interdicted, much to the vexation of more than one of our number. I say nothing about scant courtesy to the judges; I say nothing about unfairness to the Exhibitor; he is strong enough in his own line to suffer little, and can take care of himself; but I say that such an awkward piece of bungling, while calling loudly for reform in management, throws a strong side light on this exhibition generally, which, however loudly proclaimed a financial success, cannot but be a regret in perhaps more important issues. I trust it will not be without its lesson to us, and that steps may be taken to avoid its repetition. This end and aim in view, you may be pleased to accept, as in some measure, an extenuation of my sins in the pains I have put you to by so long a strain on your kind attention. PHILIP H. NEWMAN.

WEST LONDON PHOTOGRAPHIC SOCIETY'S EXHIBITION.

For the least of the West London Society's claims upon our favourable estimate of the exhibition of its members' work, held on Friday and Saturday last, arises from the commendably small number of photographs shown on that occasion. These numbered a little more than a hundred, and if, as we conjecture, they are to be accepted as representative of the Society's collective photographic skill, we are happy to admit that there were few, if any, pictures upon the walls which the most scrupulous hanging committee would venture to exclude. In fine, the task of the Judges—Messrs. Valentine Blanchard, H. P. Robinson, and G. E. Cook—must have been as difficult as it was agreeable, so high was the average of the work on view.

A frame of small views—*Morning*, *Evening*, *Calm*, *Storm*—by Miss Maud Bilton and Mr. C. Bilton, struck us as being excellently rendered studies of meteorological effect; but, if they had been medalled, to whom would have belonged the award? Photographic partnerships are a novelty. Mr. W. L. Colls towered like a Triton among the minnows with his untouched portraits taken in an ordinary room, which, if not quite so hard in the lights, would have been flawless; but they deserved their medal. Mr. J. A. Hodges, with *Softly Falls the Evening Light*, *Twilight* (medal), *The Wane of Day*, *The Icebound River*, *A Haven of Rest*, and *A Riverside Idyll*, carried off the palm for perhaps the most artistically chosen and executed series on the walls. *Blowing up for Rain*, by Mr. Lambley, a judiciously exposed and printed study of a brewing storm, deserved the medal which was given to *A Dredger, Kew*, by Mr. W. S. Rogers, a mappy study of craft on the Thames, possessing little more than technical merit. Several of Mr. Rogers' other pictures, in cool toned bromide, were killed by the unsuitable grey mounts employed.

Mr. H. Selby betrayed unquestionable technical skill in *A Welsh Valley* and *Low Tide*; but, in our judgment, his brother, Mr. L. Selby, was lucky in securing a medal for so commonplace a view as *Far from the City's Strife*, a *fin-de-siècle* young man lounging in a leafy lane, the picture having a red tone. The same gentleman showed a view of *Windsor Castle*, in which that edifice, compared with the foreground, had a most exaggerated spectral appearance. Clearly the printing was here at fault. Mr. Charles Whiting's large, boldly handled marine studies, *Early Morning*, and *Waiting for the Tide*, more than earned their award.

With scarcely any exception, the exhibition was one of which the West London Society may feel proud. We congratulate the members on the comparatively small number of portraits hung. In photography—particularly amateur photography—this is one of the things best left undone by all but a gifted few. We look forward to the next exhibition of the Society with considerable interest, as it is seldom that in so young a body we have reason to be so pleased with the quality of the work shown.

Our Editorial Table.

Mr. Charles Reid's Animal Studies.

Messrs. G. W. Wilson & Co., of Aberdeen, have sent us some examples of this well-known master's work. They are 12×10 carbon prints of *At the Smithy* and *Donkey and Cart*—two of a numerous series of Mr. Reid's pictures. We shall prize these charming productions, which, both in selection and treatment, are eminently worthy of one who has long and successfully made animal photography difficult of dissociation from his name and reputation.

The Photographic Quarterly.

London: Hazell, Watson, & Viney.

The January number opens with an article on Photo-micrography, by J. G. P. Vereker, illustrated with reproductions by the author. In a capital paper on "Impossible Photography," by H. P. Robinson, the author analyses certain American photographs illustrative of Tennyson's *Elaine*, and shows their untruth to nature at the time Elaine is supposed to have lived. There are other papers, notably one by Dr. P. H. Emerson, in which he denies that photography is art.

Hurter & Driffield's Actinograph.

Messrs. Marion & Co., Soho-square, have sent us one of these instruments, which we have not yet had an opportunity of trying. In mechanical construction it is very neat, the scales and curves being beautifully distinct. It is of a size to be easily carried in the pocket. Messrs. Marion say:—

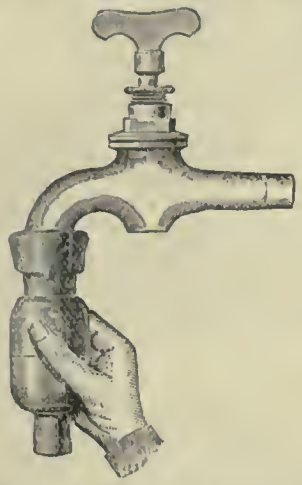
"It is a most reliable instrument, and worked in conjunction with our plates, of which the speed has been determined by Hurter & Driffield's method, we should say failures from incorrect exposures will become a thing of the past. From our trials, both of Hurter & Driffield's method of determining the speed of dry plates by measuring their densities, and of the actinograph itself, we found the results invariably correct. We have, therefore, determined to mark all our boxes of plates with the speed number. Each batch of plates will be carefully tested for speed, and the actual result given, so that users of plates may perfectly rely on the correctness of the figures, and expose accordingly; also the

speed numbers given are relative to each other. Thus, if a packet of ordinary plates are numbered respectively 17 and 20, the latter would be $\frac{3}{20}$ more rapid than the 17. Besides determining the speed of the plates, Messrs. Hurter & Driffield's method serves for giving correct time for printing positives, also correct time for making of paper bromide enlargements. For these matters we are preparing a circular giving directions."

We shall embrace an early opportunity of trying this actinograph. A pamphlet giving full directions for use, accompanies the instrument.

The Filter for the Million.

Mr. William Tylor, Birmingham, sends us a specimen of a new filter he has just brought out. It is shown, pressed up against a tap,



in the annexed cut. Although sold at a very low price, it acts most effectively, and removes all mechanical impurities from the water.

Detective or Snap-shot Album.

Messrs. Percy Lund & Co., Bradford, have issued an album suitable for the above-mentioned class of photographs. It is plain, substantial, and devoid of that showy, imitation-gold look which characterises so many of the cheap German class. The mounting boards are stated to be pure, hence there is no fear of the prints becoming deteriorated from sulphur, chlorine, or other deleterious agent.

RECENT PATENTS.

APPLICATIONS FOR PATENTS.

APPLICATION FOR AMENDMENT.

No. 13,879. 13th October, 1887. "Improvements in or connected with Photographic Cameras."

Edward Valentine Swinden and Joseph Earp have applied for leave to amend the Specification of the Letters Patent above referred to, alleging as their reasons:—"That we are advised that certain parts of the Specification set forth and claimed certain features the novelty of which was doubtful at the date of the patent."

The proposed amendments are as follows:—

On page 5.

Line 11. Altering to read: "We provide the back of the plates of the kind herein."

On page 6.

Line 46. To substitute "glass" for "brass."
Line 53. To substitute "photographic" for "photograph."
Line 56. To insert "upright or substantially upright" before "position."

On page 7.

Line 2. Altering to read, "and causing them to fall or become placed in a horizontal or substantially horizontal position."
Line 11. To insert "in an upright or substantially upright position" after "media."
Line 13. Altering to read, "said chamber, a second chamber disposed below the level of the primary chamber, and adapted to receive and hold said plates in a horizontal or substantially horizontal position as they are passed."
Line 16. To substitute "the" for "a" after "Z."
Line 19. To insert "in front of the primary chamber and" after "chamber."
To strike out lines 30 to 44 inclusive.

PATENTS COMPLETED.

New or Improved Paper for Making Transfer Pictures from Photographs.

(A communication by the firm of Zahn & Schwarz, of 6, Neue Ross-strasse, Berlin, in the Empire of Germany.)

No. 18,219. William Phillips Thompson, F.C.C., M.I.M.E., 6, Lord-street, Liverpool, and 6, Bank-street, Manchester, Lancashire; and 323, High Holborn, Middlesex.—*November* 28, 1891.

It is well known that transfer pictures are made by taking the impressions in question on the prepared side of a piece of paper which is coated with a layer of some substance soluble in water (starch, dextrine, and the like) and when the pictures are coloured with the colours in reversed order.

The colours adhere in fact not to the paper, but to the film, which is soluble in water.

If such a transfer picture be pressed with its imprinted face on the article to be decorated, and moistened on the back, the soluble coating dissolves off, the paper may be drawn off, and the picture then adheres to the article to be decorated.

As the colours of such transfer pictures often become so dry that they no longer adhere, in such cases it is of benefit to give the article to be decorated a thin coat of varnish or lacquer, which firmly retains the colour.

Paper prepared in a suitable manner may be employed for almost all possible kinds of impressions with hitherto almost the sole exception of photographs.

The film of gelatine which in this kind of print forms the printing negative must, during the printing, be kept thoroughly moistened, and is at the same time very adhesive. This latter quality is also further possessed, to a large extent, by those substances which are employed for the preparation of transfer pictures as soon as they become moist, apart from the fact that they then also easily lose their coherency.

If such paper be then laid on a rolled-up photographic negative film in order to be printed, the moisture of the layer which covers the paper is communicated thereto in consequence of the pressure exerted by the pressing frame, it becomes damp, sticky, and ceases to adhere. The great stickiness of the gelatine does the rest. Both the layers of the gelatine impression film and the transfer paper stick together, and on the drawing off the paper one or the other is so damaged that it is impossible to produce transfer pictures by means of photography in this manner.

A process for producing transfer pictures by photographic means must, however, be of very great industrial importance in view of the beauty of photographs, as these latter reproduce the originals, with all their half-tones, after almost merely mechanical preparation.

By this invention the drawback which hitherto rendered impossible the production of transfer pictures from photographs is obviated by the insertion of a layer of grease between the soluble coating of the transfer paper and the gelatine film of the original negative. This layer of grease allows the colour of the original to penetrate to the prepared transfer paper, but permits the transfer paper to be drawn off without either being injured itself or injuring the original photograph. The transfer picture obtained in this manner can be used in the usual way for transfer on to other articles.

The paper is for this purpose, after having been coated in the usual manner with a thin layer of a substance soluble in water, further prepared by placing over the layer of the soluble substance, as thin as possible, a coating which consists of fat, oil, or resin, or a mixture of these substances. The picture is imprinted on this layer of fat, the colours being very well taken up thereby. As the damp gelatine film adheres neither to the layer of grease nor to the paper, and the layer of grease also prevents the moisture of the gelatine from penetrating to the soluble substance, in this manner very complete prints are easily obtained.

The application of the layer of grease is performed, either by coating the already prepared paper according to the hardness and the kind of fat, oil, or resin, or the mixture of these latter; or, in case the substances employed have a solid condition as a whole, by rubbing it with a powder composed of these substances, or by dissolving the substance of which the layer is to consist in alcohol, ether, benzine, or any similar easily evaporated substance, and coating the prepared paper with such solution.

The paper is very valuable from the fact that it is possible to print on it direct from the photographic negative with soluble colours, which, when rubbed with varnish, become printing colours.

In this manner pictures are obtained which reproduce the tones and tints of the original far sharper and finer than the so-called stencilled pictures.

Having now particularly described and ascertained the nature of the said invention, and in what manner the same is to be performed, as communicated to me by my foreign correspondents, I declare that what I claim is :—A paper which is rendered suitable for the production of transfer pictures from photographic negatives by having a layer of grease in addition to its first preparation with a layer of a substance soluble in water.

A Portable Magazine Camera for Taking Photographs.

No. 1933. Charles Richard Beaumont, 2, Whitehall-street, Rochdale, Lancashire.—*December* 5, 1891.

This camera is of rectangular shape, and is divided into two compartments, an upper and a lower one. The upper chamber or compartment is for the purpose of storing the prepared plates, both before and after exposure. The lower chamber or compartment is for the purpose of exposing the plates to the light acting through the lens while taking the photograph. The upper chamber is fitted with a grooved plate-carrier for containing any convenient number of plates. This grooved plate-carrier is constructed to slide or travel within the chamber, over a slit cut in the division, between the two compartments. Motion is imparted to the travelling plate-holder preferably by means of a rack and pinion.

A screw or ratchet motion may also be used for this purpose.

Fitted on each of the exposure chamber, opposite the slit in the division, are grooves for the purpose of sliding the plates from the carrier to the place of exposure, and *vice versâ*. The plates are brought into opposition successively with the slit in the division of chambers by means of a milled nut on the outside right hand of camera. An indexed wheel, visible on the outside of camera, and engaging in the rack pinion, serves to indicate the number of plate or plates exposed. The grooves in which the plates slide to and from the storage to the exposure chambers are fitted with a bar of brass, or other suitable metal, for the purpose of lowering or raising the plates to and from the exposure chamber. The ends of said bar are fitted so as to slide freely in grooves, the plates resting on the bar while being lowered from, or raised to, the storage chamber. This sliding bar is actuated by means of two steel arms, the ends of which are made to fit loosely in holes at each end of bar.

These arms are attached to an axle, fitted across the back central portion of exposure chamber. The said axle projects through the right-hand side of camera, and is revolved by a small lever handle, having a catch for retaining the bar at its highest position after each plate has been returned to the carrier. The slit through which the plates pass in division of chambers is closed so as to exclude light from the plates by means of a metal plate sliding within the exposure chamber.

This metal plate is actuated by means of a rod attached, which projects through the back of camera and terminates in a milled button. On the said metal plate are fitted side supports for carrying the focussing screen.

The frame of focussing screen has slots—two on each side—about quarter of an inch long, by which the screen is mounted on pins screwed into the side supports. These slots allow the focussing screen to move backward and forward in a horizontal position on the pins.

The focussing screen is held in proper position, and focal register, by means of springs, one on each side, attached to the metal plate. The sensitive-plate chamber is fitted with a sliding lid for the purpose of putting in and taking out the plates. On this lid is placed an arm, of suitable length, made from steel or other metal.

The said arm is mounted at right-angles on an axle, and moves in an arc line towards slit in division of chambers, and when at rest is directly over and in a line with the sensitive plate resting on the moving bar. The said axle terminates at the rear of camera in a small key handle, and is for the purpose of pushing the plates out of the plate-carrier into the exposure chamber, when the camera is being used on its side. The end of arm which presses against edge of plate is made of letter U-shape, and is fitted with a small roller for minimising friction. The arm is also fitted with a spring for returning it to its original position after being used.

Improvements in and in connexion with Photographic Apparatus.

No. 13502. Erwin Hacker, 31, Königstrasse, Stuttgart, Wurtemberg, Germany.—*December* 5, 1891.

My invention relates to a means for photographing in bound light.

Under the expression bound light, such source of light is implied as is entirely under the control of the photographer, that is, which may be increased, decreased, and regulated to requirement.

I not only employ direct light—i.e., that light, the rays of which meet the object directly—but also reflected light. The object of photographing in bound light is to enable reproduction in full or life size, and to distribute the light in such manner as to render the reproduction equally sharply defined all over, and to obviate a blurring of the same owing to the variation of the rays caused by the height of the object to be photographed. Photographing on this system is carried out, according to my present invention, by enclosing the object to be reproduced within a revolvable housing closed on all sides, and formed of a combination of surfaces arranged at various angles to each other, such housing gradually converging to a funnel for the reception of the source of light.

The surfaces are advantageously fitted together in such manner as to allow the angles at which they stand in regard to each other to be varied, so that the object to be photographed can be illuminated in various ways, according to requirement. The closed housing is revolubly mounted a pivot, above which the object or person to be taken is situated, so that the latter may be illuminated in various ways, and thus various light and shade effects attained. The housing may be revolved a distance covering about 270°.

In order to employ this bound light, which enables an absolutely intensive illumination of the object in question, a particular arrangement of the camera is necessary in order to prevent mirage and false reflections. For this purpose the direct traversal by the rays passing from the object to the lens, and by the reflected rays passing to the sensitive plate, must be closed on all sides—that is to say, the camera must be closed light-tight on to the housing for the reception of the object to be reproduced.

The lens is arranged inside the closed camera casing, and the latter is provided with shades arranged at intervals in order to prevent mirage and false reflections, and to strictly confine the light to the effective cone of rays.

The closure of the camera on to the housing, after the latter has been adjusted in a position according to the light required, is effected in such manner that the axis of the camera, the centre of the object and the background, if such is present, lie in one line.

[A description of certain diagrams follows, after which come the following claims.]

1. The process of photographing in bound light, to enable the perfect control and regulation of the light effects, consisting in confining the object to be reproduced in an entirely closed room or housing, having its walls angularly and adjustably arranged together and in relation to each other, said housing adapted to be light-tightly closed on to the camera, and provided also with means for the reception of the artificial source of light, substantially as described. 2. For photographing in bound light, a housing or room consisting of trapezium-shaped surfaces, formed of fabric, on frames adjustably arranged at angles to each other, said housing having adjustable light funnel, platform, and stool, and being provided with suitable means for attaching the camera, as also for the arrangement of a background, substantially as described. 3. In combination with the housing of the form described and having platform, light funnel, and background, the camera having adjustable front casing for the focus and sensitive plate, and middle casing with partitions, and lens mounted in support, said partitions being perforated as described to confine the light to the effective cone of rays from the object, said camera having further folding chamber at its rear end for the purpose, substantially as described and shown. 4. The process and device for photographing in bound light, substantially as hereinbefore described and illustrated in the accompanying drawings.

Improvements in Photographic Cameras.

No. 2279. Tom Miller, Broughton-road, Salford, Lancashire.—*December* 2, 1891.

My invention relates to improvements in photographic cameras of the class that are employed for stereoscopic purposes, or taking two precisely similar pictures at the same time.

The objects of this invention are first to place a greater or less number of sensitised plates in a photographic camera of the above description in rapid succession for the purpose of exposure, and to remove said plates successively after exposure without requiring to be touched or handled by the operator, or taken out of the camera until necessary for the development of the picture ; and, second, for obtaining either instantaneous or prolonged exposure.

In photographic cameras that are used for taking stereoscopic pictures it is necessary to employ two lenses, which are attached side by side at, or near, the front of said camera at a suitable distance apart, and to place within the camera a longitudinal division. This division has hitherto been securely attached to the camera, or has been attached in such a manner that if required to be placed out of the way it has had to be removed by the operator. In this invention I form a photographic camera for the purposes hereinbefore set forth, preferably of a rectangular shape. In the back of said camera I construct two chambers, an upper and a lower one. The upper chamber is for the purpose of retaining any number of sensitised plates in position, so that they may be used successively for taking pictures, and the lower chamber is for the purpose of receiving said plates after the picture has been taken without requiring the plates or plate to be removed from the camera.

In the floor of the upper chamber I form an opening, through which the plate, on which an object or a view has been taken, slides into the lower chamber, and allows the next plate to be exposed ; the front portion of the floor of upper chamber is placed at an angle, to facilitate the discharge of the plate into the lower chamber through the aperture in floor.

In order to place the plates in position for taking a picture, and to remove them out of the way when a picture has been taken, I employ a double cam or worm, the rounded edge of the back part of which has been flattened vertically, and the rounded edge of the front portion has also been flattened, but horizontally. When the plates are put in this upper chamber, the bottom front edge of the first plates comes in contact with a small ledge or register on the edge of the opening in floor, and the upper part of said plate rests against the back of aforesaid double cam or worm ; this cam or worm is attached to a spindle passing to the outside at end of camera. I attach a handle or a wheel to this spindle, by which to operate said cam. When a quarter of a turn is given to the cam or worm by means of aforesaid handle, the flat vertical side at back of camera assumes a horizontal position level with the top of the front plate, thus allowing the upper edge of the front plate to enter the groove of the cam or worm, and rest against the front part of said cam, the flat side of which having, by the before-mentioned operation, been placed in a vertical position.

When a quarter-turn back is given to the worm the flat sides are again placed in the positions they originally occupied, thus permitting the front plate to fall forward after exposure on to the inclined front portion of floor, and slide through the aperture into the receiving chamber underneath, while at the same time the plate next in succession is pressed forward into position for taking a picture by means of a spring inside the back of case, until it, in its turn, is caused to fall forward and slide into the receiving chamber by the action of aforesaid double cam or worm.

For the purpose of removing the longitudinal division that is affixed within the camera, between the lenses, out of the way each time that the plate upon which a picture or an object has been taken, in order to allow said plate to fall forward on to the inclined portion of floor of upper chamber, and slide through aperture into receiving chamber, I attach the aforesaid longitudinal division to a rod which is supported by brackets secured to the inside of roof of camera.

I connect one end of this rod to the front part of aforesaid double cam or worm by means of a he and she joint in such a manner that when said double cam is revolved, as hereinbefore described, for the purpose of removing a plate, said longitudinal division is also turned up against the inside of roof of camera,

but at a period slightly in advance of the time of the plate falling forward, so as to avoid contact with said plate.

By these means said longitudinal divisions will always be in a vertical position at the required time, but will be out of the way each time a plate is removed. The hereinbefore described he and she joint need not be employed if it is not intended to construct the camera with the back portion separate from the front, as said rod by which the longitudinal division is supported may be a continuation, and form a part of the rod or shaft that carries the double cam or worm.

For the purpose of obtaining either instantaneous or prolonged exposure by simultaneous admission of light through both lenses I form a V-shaped shutter, each of the upper ends of which are sufficiently large to cover aperture in front board. I attach said shutter to front part of camera by means of a pin passing through the lower part of shutter in order that it may pivot thereon. I form the lower or narrow end of shutter with a projection, and in proximity thereto I place a spring wire rod. In order to operate the shutter this rod is pulled down over aforesaid projection without altering position of shutter, but when the wire is allowed to return said wire comes in contact with the projection on bottom of shutter, and thus causes the shutter to open, when aforesaid wire passes over the projection and the shutter again closes.

The claims are:—1. In a magazine or hand photographic camera, in which two lenses are employed for stereoscopic purposes, or for taking duplicate pictures at the same time, the use of a longitudinal division affixed to a spindle, and supported so as to be removed by the operator out of the way of a plate, on which a picture or an object has been taken and replaced in position, without internal hand manipulation, in the manner and for the purpose substantially as hereinbefore described. 2. In a magazine or hand photographic camera, in which two lenses are employed for stereoscopic purposes, or for taking duplicate pictures at the same time, the use of a longitudinal division in combination with a double cam or worm, said division being supported and arranged so as to be removed out of the way of a plate, on which a picture or an object has been taken, immediately prior to said plate being released by the action of the double cam or worm, both the removal of the division and the release of the plate being performed at one operation, and without internal hand manipulation, in the manner and for the purpose substantially as hereinbefore described.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

JANUARY 12,—Mr. J. Spiller, F.C.S., in the chair.

Messrs. Scamell and Mackie were elected Auditors, and Messrs. C. Sawyer, J. D. England, E. W. Parfitt, E. Clifton, G. L. Addenbrooke, J. R. Gotz, and T. Samuels, Scrutineers for the ensuing annual meeting.

As it was necessary, in accordance with the terms of the affiliation scheme, that delegates from the Society should be appointed to act with the delegates of the affiliated Societies, Messrs. G. L. Addenbrooke, W. Bedford, and L. Warnerke were elected to act in that capacity on behalf of the Society.

The CHAIRMAN reminded members that the anniversary meeting of the Society would be held on February 9, and said that Mr. William England had undertaken to organize a dinner for the previous evening, Monday, February 8. Moreover, as Mr. Glaisher had definitely made it understood that he would not again be put in nomination as President, this would be the occasion of his retirement. He had been asked to be present at the dinner, and had consented, and he would then be officially present for the last time.

Mr. W. ENGLAND said, as this would be the last time when the President would take the chair, he hoped he would have a most hearty reception, and be well supported by the members.

The CHAIRMAN announced that January 19 was the last date for receiving nomination papers for the Annual Meeting.

Mr. T. R. DALLMEYER read a paper on *Reflections and Refractions*. Premising that he had brought the subject of reflections from the concave surfaces of lenses before the Society on a former occasion, he said that these investigations had suggested to him the possibility of constructing a lens, the back of which should be silvered, the focus of the lens itself being such as to overcome the spherical aberration of the reflecting surface. The form of lens which he had ascertained best adapted for this was a concavo-convex, or negative meniscus lens, the convex surface of which was silvered. So perfect was the correction that could be obtained in this way, that while a small telescope, that he exhibited, had an angular aperture of 2:1, he expected that ultimately he would be able to have it as 1:1.

Mr. J. TRAILL TAYLOR said he could see immense possibilities in the application of the system to the lantern. He was a stickler for intense illumination, and thought Mr. Dallmeyer had entirely hit the right nail on the head. While Mr. Dallmeyer was reading the paper, he (Mr. Taylor) was trying mentally how to get the whole volume of light in use without the interference of the poles of the arc lamp. The effect of the latter could be got rid of in the way Mr. Dallmeyer had told them. He thought Mr. Dallmeyer had shown him the same kind of mirror on a previous occasion. It had the largest aperture, without exception, he (Mr. Taylor) had ever seen, or of which he had conceived the possibility. It was a lens of three or four inches diameter, but he did not know its construction. It was impossible to pick up a lens brightly silvered on one side and note its construction. It was the very thing for searching for comets in the daytime. Applied to the telescope, it would form a "night glass" for seeing, on account of its enormous aperture, objects scarcely possible to be seen by any achromatic telescope.

Captain ABNEY had had some little experience with silvered mirrors in spectroscopic work. In photographing the ultra red rays, a quantity of light was a desideratum, as the exposure was so long. His form of collimator was originally a silvered mirror, but he had found it tarnish so much that he had had the back of a lens silvered. There was a certain amount of spherical aberration, but he got a large beam of light, which gave satisfactory results. As to the means of getting rid of spherical aberration, Mr. Dallmeyer apparently did it completely. As to the application to the optical lantern, it had been done in the physical laboratory at South Kensington. They got bright images, but nothing like those possible here. He had had a good experience of the electric light, and had tried a mirror at the back, but the drawback was the interference of the poles. It seemed to be impossible to get a clean image on the screen. By revolving the apparatus they might get rid of the shadow. It would have to be rotated about twenty times a second. It was sometimes a useful way of getting rid of defects to rotate an image, if the thing itself could not be rotated. Professor C. V. Boys had gone a great deal into the use of silvered mirrors, by which he was able to deduce radius of curvature.

Mr. TAYLOR asked if there was a reasonable probability of the application of the system to photographic purposes. In the Daguerreotype days Beard had a patent for taking images by reflection instead of by a lens. There were circumstances under which it might be desirable to take small photographs in an imperfectly lighted room, and he could see the possibility of this system being exceedingly useful.

Mr. DALLMEYER observed that, in using a combination instead of a single lens, every drawback could be overcome.

Mr. CHAPMAN JONES questioned the use of a mirror for taking photographs with very rapid plates. With slow plates the light diffused inside the apparatus might not matter, but with very rapid plates it might have a disastrous effect.

Captain ABNEY said he used very rapid plates indeed for spectroscopic work, and found no difficulty. If the mirror was bright, light could be excluded without fogging the plate. No light came in except that which formed the image. Light could be excluded, but the mirror must be bright.

Mr. JONES said Captain Abney referred to a beam of light. There was a difference between this and the general light of an ordinary object.

Mr. TAYLOR drew a diagram of the apparatus to which he referred, and pointed out, from the position of the plate and the reflector, that there was no fear of daylight getting to the plate.

Mr. JONES also sketched the apparatus of which he spoke. It was of different construction, and admitted light all round.

Captain ABNEY said the system Mr. Taylor sketched was the one he adopted.

A vote of thanks was passed to Mr. Dallmeyer for his paper.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 7.—Mr. P. Everitt in the chair.—There was a large attendance.

Mr. J. HAY TAYLOR exhibited Staniforth's jet-holder for raising and lowering the lantern jet, and also Archer's dissolver, upon which he had himself made some improvements, and to which a modification of Wrench's rising stage was fitted.

The CHAIRMAN showed one of Messrs. Hurter & Driffield's actinographs recently brought out by Messrs. Marion & Co., and said he thought the action of the latter firm in issuing this actinograph, and marking their boxes of plates with the inertia number, was one of the most important steps taken in recent years in the direction of assisting photographers in obtaining correct exposures. Messrs. Hurter & Driffield had determined the light curves of the various hours of the day, and gave a scale of them, together with the diameter of the stop in proportion to the focal length of the lens; also another scale which gives the speed numbers of the various intensities of light. Another series of numbers are given for various classes of subject. The Chairman then explained the working of the instrument.

Mr. W. E. Debenham produced two faded transparencies handed to him the previous week by Mr. J. Traill Taylor to try the effect of Schlippe's salts upon them. One of the transparencies had been brought to such a degree of intensity that another negative and transparency could be made from it. The other image had hardly been improved; so probably there was hypo in the picture.

Mr. P. H. NEWMAN then read a paper on *Some Recent Exhibitions* [see page 39].

The CHAIRMAN hoped the paper they had just heard would lead to some improvement in the conduct of exhibitions, whether at Pall Mall or elsewhere. Their Association had no status with regard to the Exhibition, but they had

recently been affiliated to the Society, and therefore it was a question whether their opinion of the Society should be made known. One point with reference to the Pall Mall Exhibition struck him, and this was, upon what principle were the various medals awarded—for what class, for what purpose, and for what [illegible] Upon what considerations were the Judges guided in the various classes of work? Everything in connexion with the Society was in such a vague state that they ought to get some definite idea with regard to its proceedings.

Mr. DEBENHAM reviewed all the circumstances of the Davison incident, and defended the action of the Hon. Secretary of the Photographic Society of Great Britain.

Mr. T. BOLAS sympathised with Mr. Newman's aspiration that there might be a better condition of things at future exhibitions. That better condition of things seemed to him (Mr. Newman) in having no definite time for sending in pictures. In any exhibition where medals are awarded there should be a limit of time, and no picture should be received after the recognised time.

Mr. F. A. BRIDGE thought late pictures should not be shown at all, either not for competition or otherwise.

Mr. DEBENHAM was of opinion that, if an exhibition could be improved by showing pictures as not for competition, there was no particular objection to such a course.

Mr. BECKETT questioned the utility of discussion on this point.

Mr. DEBENHAM pointed out that Mr. Newman had raised the point in his paper.

Mr. BOLAS observed that the London and Provincial Association was affiliated to the Society, and therefore some expression of approval of that body's action would not be out of place. He thought a formal resolution could be submitted to the members.

The CHAIRMAN, having ruled that such a resolution would be inadmissible before the end of the discussion, went on to inquire to what extent retouching might be allowed.

Mr. J. S. TSAPE thought there was another phase of the question. If a damp sponge were passed over a great many exhibited photographs, they would present a different appearance. He would like to ask Mr. Newman whether it would be considered legitimate, when an artist could see where his picture could be improved by careful hand work, the same applied to photographs.

Mr. NEWMAN, in the course of his reply, said, with reference to Mr. Tsape's and the Chairman's questions, that he himself had come there for information on those points. He wished to know whether Judges should not be supplied with unretouched prints. He disclaimed any personal feeling in regard to the late [illegible] but sincerely thought the Assistant Secretary quite correct in his [illegible] as to Mr. Davison's pictures. The suggestions he had made for the benefit of future exhibitions would save the Judges a world of trouble.

On the motion of the CHAIRMAN, seconded by Mr. F. A. BRIDGE, a hearty vote of thanks was passed to Mr. Newman for his address.

Mr. THOMAS BEDDING then brought forward the following resolution, which, he said, from his knowledge of the [illegible] he had great pleasure in moving:—"That as the action of the officials of the Photographic Society of Great Britain in connexion with the recent Exhibition has been brought before this Society, the members of the London and Provincial Association now [illegible] to express approval of their action, and believe that the conduct of future exhibitions will be beneficially influenced thereby."

This was seconded by Mr. C. H. CREAR, and, on being put, was carried [illegible]. The meeting then adjourned.

Camera Club.—January 7.—A lecture, illustrated by lantern slides, was delivered by the Rev. A. R. W. WHARTON, M.A., upon the subject of *The Ammergau Passion Play*. Mr. W. Clarke occupied the chair. The striking characteristics of the villagers and the play at Oberammergau were well brought out by the lecturer in an able address, as well as by the [illegible] which were shown. Some discussion followed the lecture, in which Messrs. J. S. Wharton, J. Pennell, and the Chairman took part. On January 21 Mr. A. Maskell will read a paper on *Photography and Artistic Merit*. The subject will be illustrated. Meeting at eight p.m.

Holborn Camera Club.—January 6, Mr. D. R. Lowe (Vice-President) in the chair. Mr. HERBERT THOMPSON gave a lecture on *Kallitypy*, No. 2. The paper usually recommended platinotypes, and the exposure was judged in the same manner, the printing being continued until the detail in the highest lights showed [illegible]. The sensitiveness of kallitype paper was considerably greater than either, and the paper must be examined in a very weak light. Clouds could be printed in by double printing, in the same manner as printing on silver paper. The paper was developed in the following bath, for black tones—[illegible]; water, 10 ounces. Mix and add [illegible]. Any unexposed paper, after soaking, might be left in the bottom of the bottle. To the above solution twelve to fifteen grains of a mixture of [illegible] were added. Prints developed in [illegible] salt alone were not of a pleasing tone. The addition of borax gave greater transparency to the shadows, and produced a black tone. A smaller quantity of borax produced prints of a purple tint. The bichromate of potash was an accelerator, and its effect was to give contrast. A great amount of control was given by this substance. By using less than the normal quantity, soft prints might be obtained from hard negatives, and by increasing the quantity flat or [illegible] negatives might be made to yield brilliant prints. A very small quantity makes a considerable difference, and great care must be exercised in adding it, for too much would be added, and the effect would be a muddy and [illegible] print. The print should be left in the developer for about twenty or thirty minutes, so that the conversion of the iron salts into a metallic form might be complete. The prints would appear to be developed in a much shorter time, but if removed too soon the iron would not be removed in the [illegible] bath, with the result that the prints would be liable to fade, and [illegible] means would appear to some after-stage of the process. After development place the prints directly into the fixing bath (four drachms of [illegible] to the quart of water). The prints should be freely moved in the fixing bath for about ten minutes, and then passed through a second bath of the same strength, to ensure perfect fixation. After fixing, the prints were washed for about ten minutes in several changes of water, then placed on a sheet of glass to drain, blotted off between clean blotters or cloths kept specially for the purpose—free from acid or hypo—and spread about to dry in the air. If left in a wet condition between the cloths, stains are liable to appear. Some excellent prints, kindly lent by the Birmingham Photographic Company, were passed round.

North Middlesex Photographic Society.—January 11, Annual General Meeting, the President (Mr. J. W. Marchant), in the chair.—Five new members were elected. The balance-sheet showed the funds of the Society to be in a satisfactory condition, notwithstanding the heavy demands made upon them to carry out the numerous improvements projected during the year. The President then read his report of the year's work, showing a large increase in the membership and increased activity in all branches of work by the members, giving thanks to Messrs. Gale and Robinson, the Judges at the Exhibition, and to those gentlemen, non-members and members, who had assisted the Society with lectures and demonstrations during the year. The report was unanimously adopted. Votes of thanks were accorded to the retiring officers and Council. Several alterations in the rules were made, and the following officers and Council were elected:—*President:* Mr. G. W. Marchant.—*Vice-Presidents:* Messrs. H. Walker and F. L. Pither.—*Council:* Messrs. F. Cherry, C. C. Gill, J. C. S. Mummery, H. Smith, T. C. Lathbridge, C. Beadle, J. L. Treadway, J. Stewart, J. Saville, S. E. Wall, W. Taylor, and C. O. Gregory.—*Treasurer:* Mr. F. W. Cox.—*Hon. Secretary:* Mr. J. McIntosh, 14, Lowman-road, Holloway.—*Assistant Hon. Secretary:* Mr. F. M. Ainsley. Tickets for the Photographic Society of Great Britain lectures were distributed among the members, and it was resolved that the Society should, as a body, support the testimonial to Dr. R. L. Maddox. The next meeting, which will be held on Monday, January 25, will be an exhibition of members' lantern slides.

South London Photographic Society.—January 4, Instruction of Beginners by Mr. F. W. WEBB.—The lecturer, after explaining the various movements of the camera and their uses, dealt with exposure and the methods of developing negatives, producing a considerable number of the latter to illustrate the pitfalls of beginners, at the same time giving good advice as to how these were to be avoided. Mr. Webb also produced a spectrum screen which he had made, together with photographs of the same on ordinary and Ilford isochromatic plates, which led to a long discussion as to the uses of colour correct plates, prints from Edwards' isochromatic plates, and Gotz's Obernetter films, with the negatives, being referred to the course of the discussion. By the courtesy of Messrs. Greeff & Co., samples of the rodinal developer, and of para-amidophenol, by Messrs. Hinton & Co., were distributed among the members, the results to be produced on another evening.

Brixton and Clapham Camera Club.—January 7, the President (Mr. A. R. Dresser) in the chair.—Mr. H. M. SMITH, of Eastman's Photographic Materials Company, Limited, gave a demonstration of the Kodak cameras, including the new "No. 5, folding," which, as now constructed, can be adapted for use with glass plates as well as films, concluding his lecture by showing a number of slides made from Kodak negatives through the lantern. The Chairman mentioned that he had always advocated the use of films. Subsequently to this the Incandescent Gas Light Company, Limited, gave an illustration of the method of using their light in the lantern. The opinion was that, though not so powerful as limelight, it possesses many advantages over oil, and, with some slight improvements, might be a very fair substitute where the former could not be obtained.

Croydon Microscopical and Natural History Club (Photographic Section).—January 8, Mr. W. Goode in the chair.—Mr. JOHN WEIR BROWN read a paper on *Some Further Experiments on Toning Bromide Prints with Uranium*. Mr. WEIR BROWN observed that there were many methods now suggested, and what he had done might lead others to take up study, and perfect the process. In conclusion he said: "I should like to be allowed to make a few remarks in the way of a personal explanation, there having been one or two paragraphs in the papers seeking to discount the novelty of the system I have described to you. Now, I wish to say that I have never made, till now, any claim to the origination of this process. But I have, from first to last, freely given the results of my experiments for the production of warm tones on bromide paper to the photographic public through the medium of THE BRITISH JOURNAL OF PHOTOGRAPHY, and at the meetings of this and other societies, without thought of any credit or acknowledgments which might be bestowed on me, but simply for the pleasure of being able to contribute my mite to the sum of knowledge, and for the benefit of my brother lovers of the art; but, when the good people over the water go out of their way to annex the credit that has been earned on this side, you will, perhaps, concede that it is not more than ordinary weakness of human nature to wish to speak out in defence of our claims. Those of you who remember my first publication of the uranium toning process, more than a year ago, will know that I acknowledged my indebtedness for the suggestion of the means I adopted to a formula for negative intensification by Vogel, jun., which was published in the 1891 ALMANAC. The feature of this formula was the addition of acetic acid; for uranium intensification, without the acid, was used and abandoned more than twenty years ago. I could not claim—and, as you see from what I have said, I have never claimed—to be the originator of acid uranium intensification; but have simply urged the adaptation of the formula to the toning of prints on paper. In this respect I am not aware that I have been anticipated; but, as our American friends, who, with very natural patriotism, think that all good things emanate from their side of the pond, have thought fit to try to push me in a corner, I think I may fairly venture to lay claim now to the application of the acid combination as a toning agent, until they are able to show a prior publication."

Richmond Camera Club.—January 8, Mr. Cembrano in the chair.—Mr. ENNIS read a paper on the recent exhibition of the Photographic Society of Great Britain. After commenting on the return to warm tones and other general features of the exhibition, Mr. Ennis called attention to the pictures of most of the leading exhibitors and others worthy of notice, his remarks showing that considerable artistic knowledge had been brought to his study

of the exhibits. He also remarked upon the carelessness and lack of taste shown in too many instances in the mounting and framing of the pictures, many of which were spoilt by the obtrusive ugliness of their accessories. The discussion was continued by Messrs. Cembrane, Davis, Ardaseer, Whipple, and others.

Herefordshire Photographic Society.—January 5, Lantern evening.—The competition slides were put on the screen in order of merit. The next lantern evening will be held on Tuesday, February 2.

Lewes Photographic Society.—January 7.—A collection of prize slides was shown. Mr. Percy Morris, School-hill, Lewes, having consented to act as joint Hon. Secretary to the Society, communications should be addressed to him until further notice.

Sheffield Photographic Society.—January 1.—Mr. PAUL LANGE (President Liverpool Amateur Photographic Association) gave a lecture on *Norway*, illustrated by limelight views.

Rotherham Photographic Society.—January 5, Paper by the President (Dr. F. B. J. Baldwin) on *Focussing*.—In a very comprehensive way the subject was dealt with, special negatives having been prepared for illustration. Pinhole work and the uses of lenses were also referred to. The general business of the meeting included the granting of a guinea to the Maddox Testimonial Fund, and the passing of a vote of condolence with the family of Mr. Luke Berry, a member of the Council, and whose death had occurred since the previous meeting. Mr. T. W. Mosby was elected to the vacancy.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

THE TELEO-PHOTOGRAPHIC LENS.

To the EDITOR.

SIR,—I regret I cannot compliment you on your editorial comment on my paper recently read at the Camera Club, at least as regards yourself. It is no "inconvenient reproach," or reproach at all, to me that I do not carry in my head a list of the efforts that your paper has chronicled for the last eighteen years of what has been attempted, and not done. I may again remind you that I invited you to call at my office on September 24 last—prior to my first "application"—with the object of showing you the new instrument and its performances. I did that with the object of asking you in a friendly way if your long and practical experience had ever led you to believe that such an instrument had before existed. On that occasion, in addition to showing you the image-forming powers of the lens, I also showed you that its construction permitted of its being employed as a Galilean telescope. It was in reference to this matter that you were good enough to express astonishment; and I think my memory is to be trusted, inasmuch as an expression of "astonishment" from a man of your practical experience would naturally be construed by me as a confirmation of its novelty, and would, therefore, be impressed upon my mind. However, let me call your attention to one or two facts. You say, "It was only at the Camera Club that we learned, for the first time, the construction of the negative lens of the combination;" yet you did not deny that I had made a rough drawing of the combination for you on October 13; and, in your editorial notice on my letter referring to this fact, you state "the drawing referred to by Mr. Dallmeyer was a positive lens (achromatised on the Gauss principle), with a negative lens placed in the same position as that shown in Dr. Miethe's drawing." Thus, sir, it appears you did not have to wait for the Camera Club meeting, as you infer, to learn, for "the first time," the construction of the instrument.

Again, in your issue of the October 30, when Dr. Miethe first contributed anything on this subject, he states, "It is formed on the principle of the Galilean telescope; but, having reference to the object in view, it differs considerably in detail from it." There is no editorial comment to that letter proclaiming the lack of novelty of construction. Again, when I wrote to know Dr. Miethe's date of "application," in your editorial comment you note the date of my "application," and only ask, "Can Dr. Miethe antedate this?" The above remarks speak for themselves as to the matter of memory between you, Mr. Editor, and myself.

Now, as to the quotations in your last issue. What do they prove? That the adaptation of the Galilean telescope for ordinary photographic purposes has been found useless. When attempts have been made to use it, the few experiments related are accompanied by the expression, "Although there is a fair degree of sharpness in the centre of the picture, it unfortunately does not extend to any distance from the centre." Again, "When used as an objective for the camera, it produced images of great sharpness in the axis."

I notice your extract from the ALMANAC of 1877, with reference to an image of the sun being taken. That I can quite understand; but it was the sun, remember, with its great amount of light, and nothing else, that was produced. It was not a pastoral subject taken on a November day! A Galilean telescope is not a photographic lens. The corrections, the manner of use, and disposition of the pencils of light, in employing the Galilean telescope as a telescope, are essentially different from employing the same instrument as a photographic lens, and, as such, of course it is practically useless.

I conceived the advantage that would accrue in constructing a photographic lens having the property of a very wide range of foci in itself by slight adjustments of the lens and focussing screen, accompanied by other advantages such as have, I believe, never existed in any photographic lens hitherto constructed.

In your leader of the 19th of September, 1873, a part of which is quoted in your last issue, you omit, curiously enough, the concluding paragraph, which you particularly pointed out to me at the Camera Club after my lecture. It is as follows:—"Opticians have done all in the way of making wide-angle lenses demanded by photography or permitted by theory; but it might be worth while to devote some attention to the opposite side of the question, and see if a combination could not be made which would project on the ground glass of a camera of moderate length an image of three or four times the apparent magnitude of objects in nature. That such a lens would create useful applications for itself cannot be doubted." That, Mr. Editor, if you will allow me to say so, was worthy of your practical acquaintance with what had been accomplished in photographic lenses, and a valuable hint as to a novel direction for those competent to work in, in order to advance the science of photography.—I am, yours, &c., THOMAS R. DALLMEYER.

25, *Newman-street, Oxford-street, W., January* 11, 1892.

[With respect to the "inconvenient reproach," is it not always considered a portion of the duty of a patent agent to search likely records to ascertain whether the invention to be patented is new? We repeat, it was only at the Camera Club meeting that we first learnt the construction of Mr. Dallmeyer's negative lens; for on the occasion referred to, on the 13th of October (several days after the date of his application for a patent), he certainly did make a rough drawing—not of the "Combination," but of the front or positive lens only—indicating, not the form, but the *position* only of the negative lens by three elongated dashes, which conveyed no idea whatever of its construction. In regard to the covering power of our old Galilean, we said that this was limited, the sharpness being confined to only a few inches around the centre. But let it be remembered that it was mounted not on a *small* camera, such as that shown by Mr. Dallmeyer at the Camera Club, but on one the ground glass of which is twelve inches square. Let it be further remembered that no diaphragm was employed, for this was prior to the introduction of rapid dry plates, and it will be conceded that to cover even a 5×4 plate with a fair degree of sharpness, by a lens not specially constructed for photographic use, was not a bad feat for what Mr. Dallmeyer correctly terms a non-photographic instrument, although not so "practically useless" as he would have us imagine. Without going further into the matter at present, we quite endorse what we wrote eighteen years ago to the effect of the desirableness of opticians (by whom we mean practical manufacturing opticians) devoting attention to this phase of photographic optics; and we have only once more to repeat, that we are much pleased that, even after waiting eighteen years for it, our aspiration has now been fulfilled by this teleo-photographic lens of Mr. Dallmeyer, which, we know, will be useful for many purposes, and hope will meet the commercial success we feel assured it deserves.]

THE "NEW" TELESCOPIC LENS OF MR. DALLMEYER NOT NEW IN THE UNITED STATES.

To the EDITOR.

SIR,—On the table before me is a corrected meniscus of about six and a half inches negative focus, which screws into the lower end of the draw-tube of my microscope. This lens has been in use for extending the back focus of my microscope objectives (and thus doing away with an eyepiece as a projecting lens) in photo-micrography for about a dozen years. Your readers may be further interested to know that this lens was made on a formula on which years before a lens had been made by the late Mr. Telles, of Boston, U.S.A., for the late Dr. Woodward, of Washington, and with which lens, as a part of his apparatus, Dr. Woodward made his famous photo-micrographs. Further, at the same time Mr. Telles made the Woodward "amplifier," Mr. William Wales, of Fort Lee, N.J., made similar concaves corrected for photo-micrography. Messrs. Bausch & Lomb, of Rochester, N.Y., catalogue a similar lens for photo-micrography. If I am not mistaken, Dr. R. L. Maddox, of Southampton, had and used a Wales amplifier many years ago. As to the application of the principle in other directions, the great American optician (who, by the way, used fluor spar in the nice corrections of microscope objectives about twenty-five years before the secret of apochromatics was known), Mr. C. A. Spencer, of Canastola, N.Y., made *large-aperture* and *short-focus* equatorials, provided with a concave lens similar to the Dallmeyer. Such a telescope I have seen on numerous occasions. Mr. Spencer, and Mr. Tolles as well, made *short* pocket telescopes of exceptional power and definition by introducing a lens similar to the Dallmeyer. Such telescopes I have also seen. The late Mr. Malcom, of Syracuse, N.Y., I used occasionally to see at work on his rifle telescopes, which went to all parts of the world on their reputation for power and definition, the secret of which was the introduction of a concave similar to the Dallmeyer. All these makers were active a generation ago, and all but Mr. Wales death has silenced.

The famous results obtained by Dr. Woodward, and the satisfaction I have had in working with my meniscus, led me not long since to ask Mr.

Lees Curtels, of the house of Mr. Charles Baker, London, agent for Mr. Zeiss, to try to interest Mr. Zeiss or Professor Abbe in making a concave (with only two reflecting surfaces, while the projecting eyepieces now used have four) corrected for extending the back focus of apochromatics. At least on the other side of the Atlantic the principle of the Dallmeyer telescopic lens has been practically applied for a good many years. I remember constructing seventeen or eighteen years ago a telescope on this principle, copying a Spencer instrument, with two stiff paper tubes, home-made wood turnings, two lenses from half a "field-glass" and a microscope eyepiece.—I am, yours, &c., A. CLIFFORD MERCER.

London, January 8, 1892.

[The application of a concave lens to the microscope, as mentioned by Dr. Mercer, while known for many years, is not quite the same as in the Galilean telescope, in which the concave must be of shorter focus than the convex element.—ED.]

OXYGEN CYLINDERS AND GAUGES.

To the EDITOR.

SIR,—My attention has been called to a letter, signed "Arthur Seet," in your issue of the 18th ult. May I be allowed to reply to one or two statements in the first paragraph of the letter, as they seem to me rather confused, and possibly might mislead some of your readers. Mr. Seet says: "Considering the time they have been in use, there may have been quite as many accidents with cylinders as with bags." He also refers to two accidents, as proving that the coroner at Ilkeston was ill-advised in recommending the use of cylinders, instead of bags. I may say that it was the jury, not the coroner, who made this recommendation, possibly influenced, not only by my evidence, but by Mr. W. I. Chadwick's statement that he had discarded the use of bags in favour of cylinders. So far as my own evidence related to the use of cylinders, it was simply a statement that such an accident as the Ilkeston explosion could not have happened if Mr. Scattergood had been using cylinders instead of bags. If he had been supplied with two cylinders, one containing oxygen, and the other coal-gas or hydrogen, neither a mistake on his part nor defect in his fittings could have resulted in a mixing of the gases in either of the cylinders, because the pressure of gas in either cylinder while in use is greater than the pressure in the connecting tubes. I also described the precautions taken at the works to prevent accidental mixture of the gases during compression. These statements, and the fact that, since high-pressure cylinders were introduced—now seven or eight years ago—there has never been an accident with one of them outside the works, moved the jury to add their recommendation to the verdict. As there are now thousands of cylinders in use, and as every user of them has had to learn how to use them in this short period, I submit that the jury were not so ill-advised as Mr. Seet appears to think. The two typical accidents referred to by Mr. Seet do not affect the above statements, I think. The first of them happened in the works, under special conditions not likely to occur again. Of course, workmen run special risks when filling high-pressure cylinders which are not shared by the public, and there have been several accidents in the works, which, however, do not suggest that the public run the risk of similar ones. Indeed, one of the safeguards which the public may be said to enjoy is the fact that, should a cylinder be in any way untrustworthy, or the filling of it in any way careless, the chances are that the man who fills it will suffer any unpleasant consequences which may ensue. The second accident referred to was caused by the explosion of a gauge, not of a cylinder. The risk of such accidents is not inseparable from the use of cylinders. Of course, cylinders cannot be used without fittings, and, in a sense, accidents with fittings may be classed as accidents with cylinders. But a distinction should be drawn more clearly between them, I think, than is drawn by Mr. Seet, because dangers in the use of fittings have to be, and, I think, can be, specially guarded against. As regards the cylinders themselves, the conditions of safety have been pretty thoroughly ascertained, and are so simple that every user may obtain the knowledge of them on which alone an intelligent confidence in them can be based.

With respect to gauge explosions, I should like to add, while writing to you, that I think, sir, your condemnation of the Bourdon high-pressure gauge, in your issue of the 11th ult., was too sweeping. There is strong reason for the belief that all explosions of gauges hitherto have been caused by the ignition of hydrocarbon in some part of the gauge-tube or connection by the heat liberated when the column of air in the gauge-tube is suddenly compressed by the rapid admission of high-pressure oxygen, as pointed out in the article of mine which you kindly published in your issue of January 9, 1891. Since writing that article, I have observed that the presence of an explosive mixture of gases in the tube is not at all necessary for the ignition of this hydrocarbon. The sudden compression of the air in the tube is quite sufficient. When the gauge is properly fitted with a check to prevent a sudden admission of oxygen, or when proper precautions are otherwise taken to prevent this sudden admission, no explosion can occur. My Company have sent out some hundreds of gauges so fitted, and we have never heard of an accident with them. I may add that this precaution of slowly admitting oxygen from a high-pressure cylinder should always be observed when using any connexion which consists of a closed tube which may contain traces of grease or hydrocarbon.—I am, yours, &c., W. MORTON JACKSON.

Manchester Oxygen Company, Limited, Manchester.

To the EDITOR.

SIR,—On January 25, Mr. C. F. Budenberg, of the firm of Messrs. Schäffer & Budenberg, one of the largest makers of gauges, will give a paper on *Pressure Gauges for High Pressure Gases* before the Lantern Society, at 20, Hanover-square.

If any of your readers have any remains of gauges or regulators which have exploded or fused, I should be very much obliged if they would lend me them for the occasion.—I am, yours, &c.,

CHARLES E. GLADSTONE, *Hon. Sec.*

6, *Bolton-street, W., January* 12, 1892.

THE PHOTOGRAPHIC SOCIETY.

To the EDITOR.

SIR,—The doings of the Photographic Society of Great Britain have lately attained such prominence that it may seem unnecessary to remind members that we are almost on the eve of the annual meeting and election of officers, and that nominations must be sent in by the 19th instant. I would earnestly beg my fellow-members to take a more active interest in the affairs of the Society than they have hitherto done, and not only to send in nominations for Council and officers, but to attend the annual meeting and exercise the privilege, which can only be enjoyed on that occasion, of offering criticisms of the past and suggestions for the future. At the annual meetings for some years past, out of the hundreds of members, only a handful have been present in addition to the members of Council. Cannot this be remedied next month? The new Council will certainly enter upon their duties with more zest if they feel that the members are taking a lively interest in their doings, instead of "sitting on the fence," and waiting for an opportunity of catching some one tripping.

I am actuated by no party spirit in making these remarks, but only desire to point out that no Council, however good, can assure the prosperity and success of a Society without receiving the cordial and spontaneous support of its members.—I am, yours, &c., EDGAR CLIFTON.

27, *Hanley-road, Hornsey Rise, N.*

AN EFFICIENT HAND CAMERA.

To the EDITOR.

SIR,—In your "Answers to Correspondents" in THE BRITISH JOURNAL OF PHOTOGRAPHY, December 11, 1891 (to which my attention has been directed by a friend, and which I had overlooked, otherwise I should have replied before this), I find an article of mine is called in question that was inserted in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for the present year.

Although I have had no intention of patenting the camera or protecting it in any way, I cannot see how I can have copied Mr. Miller's camera, when my first and only knowledge of its existence is shortly described in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for the present year, although I have searched in volumes and ALMANACS for 1890 and 1891 without finding any mention of it. In sending the short description given in the ALMANAC for the present year, Mr. Miller claims that his camera is free from springs and pushes; mine has both. Will Mr. Miller kindly state wherein my apparatus is like his invention?—I am, yours, &c.,

Southampton, January 6, 1892. GEO. W. VALENTINE.

FRENCH PATENTS.

To the EDITOR.

SIR,—Your very interesting last number duly to hand. Allow me, please, to make a slight suggestion *re* your "French Patents," page 21. You say England has taken more patents than France. There is always two sides to a question, and the other side is, Which are the most *valuable*, and the most *in actual use*? It is easy to take out a patent, but to sell the article is another thing. Then, again, maybe the Frenchman is more liberal; if he invents something good, he may be apt to give the benefit to the general public. This may be worth your while looking into when you put *la Perfide Albion* against *la Belle France* in comparison as to patents and their *actual value*. Not long ago you found yourself patents taken out too lavishly for trinkets never used.—I am, yours, &c.,

Asnières, January 9, 1892. ALBERT LEVY.

Exchange Column.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

**** Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," *2, York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

A. H. Poole, Waterford.—*Parade of police on the Mall, Waterford. The High Sheriff announcing result of poll from Town Hall, Waterford. Mall and Town Hall, Waterford. Waterford from Mount Misery.*

HALIFAX.—The picture should face page 514 of the volume.

T. EDGR.—Apply to Winsor & Newton, or to Newman, Soho-square.

W. MELLING.—There is something wrong with the crayons. Try black chalk.

JOHN W. MARKS.—Try a mixture of dragon's blood and aurine in spirit varnish.

F. WILCOCKSON, F. K. Barclay, General Dawson, and others.—Received. Thanks.

CONSTANT READER.—Of Messrs. Eyre & Spottiswoode, Fetter-lane, E.C., at the cost of a few pence.

C. BENNETT.—We believe that you would be liable to the duty if you used a patron's arms and crest for your card.

P. C. PORTER.—To re-black diaphragms first thoroughly clean and then treat with a solution of silver and copper nitrate, and apply heat.

K. MICHAEL.—Recommending "good paying businesses" is hardly within our province. Advertise in the outer columns of the JOURNAL.

B. J. S.—Coat the wooden dish with a mixture of beeswax and resin. These must first be melted together in the proportion of one of resin to two of wax.

E. WEEKS.—While it is grossly uncourteous in the Belfast advertiser not to have replied, he may possibly be in communication with the foreign photographer.

J. C. S.—Dry soda and potash carbonates will suit either dry eikonogen or hydroquinone. You will find various formulæ for the proportions at pp. 767-773 of the ALMANAC.

SOMERSET.—The developer appears to us far too strong in sulphite, which, in the proportion you name, would have a very marked restraining action. Try the effect of reducing it, say, to four ounces.

GREENHORN.—They are principally done in Germany by a photo-mechanical process, but we cannot give you the address required. Apply to some large firm, such as Waterlow's or the London Stereoscopic Company.

R. GRAVES.—As a rule, coloured photographs are not admitted into photographic exhibitions. An exception is, however, usually made in the case of photographs coloured mechanically—photo-mechanical prints in colour, for example.

W. P. W.—The yellowness was probably due to citrate of silver, which blackened in the light. The yellowness would have made no difference in use. Make up a fresh solution and keep from the light. Any good soft gelatine will answer.

W. M. L.—To make small negatives from large ones, first print a transparency from the negative by contact. Then from that make the small negative in the camera. Proceeding in this way, there will be no difficulty in obtaining any amount of "pluck."

W. DEE.—The majority of the illustrations referred to are by the zinc-etching method. A print from a negative, from a drawing specially made for the purpose, is made on zinc in bitumen or bichromated albumen, and then bitten in with dilute nitric acid.

W. A. J.—In printing on bromide paper by artificial light, there is no necessity to interpose ground glass between the light and the negative, supposing the light is a moderate distance away. The ferrous oxalate developer is the one most used for the purpose.

PARSEE.—Procure a copy of the current ALMANAC. In it you will find all four of the formulæ you are inquiring for, also many others that will assist you. For negatives pyrogallic acid is the developer most generally employed here, and for bromide paper the ferrous oxalate developer.

A. DIGBY.—With a lens of the "rapid" type of twelve inches focus you will not succeed in copying a line engraving, sharp to the corners, without a very small stop is employed. Indeed, then we doubt if the result will be satisfactory. A lens of longer focus should be employed for such work.

BLUE.—Unless your consumption is much larger than we gather from your letter it is likely to be, our opinion is that you will find it cheaper to purchase the paper ready prepared than to prepare it yourself. Some little skill is necessary to coat very large sheets evenly, and some waste must be entailed until it is acquired.

ASSISTANT writes: Could you help me out of this difficulty? I am trying to retouch on an unvarnished negative with medium, but the strokes show in the printing. I have followed the instructions—put it on very thin and also thick, and tried all ways. Why I think it is the medium's fault is, because I retouch always on a varnished negative with a surface got by resin, and I am now trying on unvarnished negatives, and cannot succeed on them. I can retouch very well on the others (varnished)."—It would seem that the medium is put on too thickly. Only a mere trace should exist on the negative. If a thinner coating does not obviate the difficulty, try another sample of medium.

JAS. TAYLOR writes: "I will be obliged if you will advise me through THE BRITISH JOURNAL OF PHOTOGRAPHY how I can preserve the black in finishing bromide enlargements with chalk (*Sauce Velours*). I rub the enlargement with powdered pumice to give a tooth, and on stumping I always get it to work brown."—Perhaps some of our readers who are *au fait* with chalk work will supply the desired information.

P. H.—There are no works published on photo-mechanical printing in colours. All those who are the most successful workers in the higher branches of photo-mechanical work keep the details of their methods as trade secrets. All that has been published on the subject has, from time to time, appeared in back volumes of this JOURNAL. A brief description of most of the methods will be found in Burton's *Photographic Printing Processes.*

W. SHAWCROSS.—1. The word "achromatic" means freedom from colour. Some field glasses are achromatised by having each lens formed of three component parts, and this permits of a greater magnifying power being attained. But brilliancy of image, with less magnification, can be secured when the front glass is formed of only two elements, and the eyepiece of one. 2. You may continue the use of the indiarubber sheeting without the apprehension of any injurious effect.

S. HOPKINS sends some prints (vignettes), mounted on chocolate-tinted mounts, that are badly stained in the whites, and wishes to know the cause. He adds, there are no stains on the pictures before they are mounted; they only appear when they are dry and ready for rolling.—It is the fault of the mounts. The coloured surface is soluble in water. If it be wetted with the tongue, the colour comes off; if touched with the finger, such mounts are sure to stain.

A. ANDERSON wishes to know how he can take portraits at a fancy-dress ball which is to be given at the local assembly-rooms next month? He says the electric light will not then be laid on, and wants to know the next best light to use, and also our opinion as to whether taking portraits on speculation would be likely to prove remunerative.—The best light, next the electric, to use under the circumstances is the magnesium flashlight, and it is the light most generally employed for such purposes. With regard to the commercial question, we cannot offer an opinion beyond saying it is frequently done.

J. P. says: "A month ago I made up a saturated solution of sulphate of iron, and filtered and acidified it, and next day used some for making ferrous oxalate developer. It was then all right. On going to use it a few days ago, I was surprised to find that a great deal of the iron had separated, for there were a lot of crystals at the bottom of the bottle. What could be the cause?"—What has taken place is simply this: A saturated solution was made at a certain temperature, and has since been subjected to a lower one, consequently a portion of the iron salt has crystallised out. A saturated solution at one temperatnre may become a supersaturated one at another, and therefore deposit some of the salt. It is always better to make solutions to a definite strength than to use "saturated" ones, which are always more or less indefinite.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—January 18, 1892, Social Evening.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—January 21, Monthly Lantern Night. Visitors invited.

PHOTOGRAPHIC CLUB.—January 20, *Stereoscopic Photography*, Mr. J. Nesbit. January 27, Annual Lantern and Musical Entertainment (ladies' night).

NORTH LONDON PHOTOGRAPHIC SOCIETY.—January 19, 1892, Mr. E. Clifton, *The Dark Room.* Commence at 8.15 p.m. Visitors are invited.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.—Annual meeting, January 19. Mr. J. Brown will read a paper on *Platinum Toning as applied to Gelatino-Chloride Paper.*

MESSRS. WALTER GRIFFITHS & Co., of Highgate-square, will shortly open new premises at 5, Union-passage, Birmingham, as a general store for photographic materials and apparatus. Mr. M. O. Suffield will have the management of the new depot.

BRIXTON AND CLAPHAM CAMERA CLUB.—January 21, *Printing Processes.* February 4, Address by Mr. A. Pringle. 18, *Lenses, their Properties and Uses.* Mr. Henry Crouch. March 3, Open Lantern Night. Slides shown and described by Mr. B. G. Wilkinson. 17, Annual General Meeting.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—January 19, Lecture by Mr. Chapman Jones on *Distortion of Outline in Photography.* 26, Discussion on the *Relative Merits of Different Processes for the Production of Lantern Slides.* February 2, Lecture by Professor R. Meldola, F.R.S., on *Photography as a Branch of Technology.* 9, Anniversary Meeting. 23, *Printing Out Emulsion Papers.*

IN consequence of his engagement with Messrs. John J. Griffin & Sons, Limited, of 22, Garrick-street, having terminated on December 31 last, Mr. R. C. Murray announces that he has opened premises at No. 8, Garrick-street, W.C., for the manufacture and sale of photographic apparatus, materials, and chemicals. Mr. Murray's long experience as a practical photographer and as a manufacturer of apparatus should be a complete assurance that the interests of purchasers will be safe in his hands. We wish Mr. Murray every success.

POTASSIUM FERRIDCYANIDE AND AMMONIUM SULPHOCYANIDE REDUCER.

In the reduction of over-dense negatives by chemical, as opposed to mechanical, means, two simple principles have long been utilised. These are the conversion of the metallic image into a salt of silver, and the dissolution of the converted portions of the picture in hyposulphite of soda. In so far as gelatine dry-plate work is concerned, these principles are subjected to little, if any, variation, and they probably form the basis of most, if not all, the reducers in common use.

Typical of these, and at the same time the one most generally employed, is Farmer's solution. This, as our readers well know, consists of a mixture of ferridcyanide of potassium and hypo. The action of the first-named body upon the metal of the negative image is to change it to the state of silver ferrocyanide, which salt is soluble in hypo. Practically speaking, it is possible in this manner to remove the whole of the silver from a negative, leaving what is virtually a clear film on the glass. We say virtually, because hardly any reducing solution that we are acquainted with is capable of taking out the whole of the impression from the gelatine, in which, after all the silver has been dissolved away, a faint image generally remains, the composition and the cause of which have never yet been clearly explained.

From the foregoing it will be evident that the strength of potassium ferridcyanide determines the degree of reduction of the negative, and this fact obviously affords considerable scope in its application. Local, as well as slight general, reduction is thus easily effected, whether a negative or a silver positive on paper be in question, the function of the hypo being simply to dissolve out just so much of the picture as has been altered to silver ferrocyanide.

One advantage of reducers of the ferridcyanide and hypo class is that they may be employed before the negative is fixed; but, in actual practice, we do not think that this advantage is much availed of. It is most likely that reduction of a negative is not decided upon until it has been fixed, washed, and dried. It is a moot point whether photographers would not prefer to use a reducing solution in which their old friend and enemy, hypo, played no part, since it is apparent that, as a solvent of the converted image in reduction processes, it demands hardly less care in removing its last traces than when it is employed for dissolving out the unaltered portions of the newly developed negative.

Such a plan—one, that is, not involving the use of hypo—is at hand in that recently proposed to us by Mr. A. Haddon, and by him subsequently brought before the Society of which he is a member. It will be recollected that in our article of December 24 last, describing Mr. Weir Brown's modified uranium toning process, the total removal of the developed silver image was stated to be effected by Farmer's solution of ferridcyanide and hypo. Mr. Haddon points out that there is considerable danger to the stability of the uranium image possibly from the hypo itself, which may be alkaline, or the washing water, which may also have a similar reaction, an alkaline solution easily dissolving ferrocyanide of uranium. He further goes on to suggest the removal of the developed silver image by means of a solution of potassium ferridcyanide and ammonium sulphocyanide, the latter taking the place of hypo as a solvent of silver ferrocyanide. This solution may be used in an acid state, and thus all danger to the stability of the uranium picture is averted.

Mr. Haddon made several other suggestions of probably considerable value in connexion with uranium toning, to which we may advert on a future occasion. For the present, however, we will content ourselves by pointing out the applicability of potassium ferridcyanide and ammonium sulphocyanide as a reducer for negatives as well as silver positives on paper. We have ourselves submitted it to practical tests, both with very dense negatives and over-developed bromide prints, with satisfactory results. The ferridcyanide is best employed in a weak solution of from five to ten grains to the ounce, the sulphocyanide being, of course, used in considerable excess. Apparently the mixed solution keeps well, although, of course, we have not been able to give it an extended trial; but, in an acid state, its activity is much retarded, while, on the other hand, its tendency to stain is diminished. Used in a comparatively powerful state of concentration, we have observed that it is most energetic as a solvent of silver, and hence we repeat that a weak solution is best in use, otherwise the half-tones of the picture are placed in danger.

As we have before remarked, where there is a desire to avoid using hypo in reduction methods, the above plan of Mr. Haddon's will commend itself. We shall watch with interest the practical experiments and experiences of those who may be tempted to give it a place in their formularies.

VIGNETTING ENLARGEMENTS.

Vignetted busts are undoubtedly the most popular form of enlargement at the present day, and, when well executed, there cannot be a more pleasing style of portrait; but, if the vignetting be badly or carelessly done, no matter how otherwise good the picture may be, the result is worthless from an artistic point of view. So well recognised was this fact in connexion with *carte-de-visite* and cabinet portraits, that vignetting has been almost regarded as a higher branch of printing, and, in most instances, a special price—fifty, or sometimes a hundred per cent. over that of plain prints—was charged.

Numerous were the devices adopted in order to secure the most perfect gradation possible; indeed, almost every printer of any standing had his own particular method. From the well-known "vignetting glass," which, though theoretically perhaps the best expedient, was in reality the most unsatisfactory, through various styles of more or less elaborate marks, we might pick our way from improvement to improvement without arriving at perfection, and even with the best of these numerous aids, as much was, perhaps, left to the skill and care of the printer as the vignetter itself performed, the common vignette glass alone excepted, for this defied the highest skill to better its results. Theoretically, we say the principle of the vignette glass was as near perfection as possible; a sheet of coloured glass, "flashed" on one side with a non-actinic pigment, had an oval or other shaped aperture etched out in its centre until the whole of the colour was removed, and the edges of this opening were gradually softened by the same means until the full depth of tint imperceptibly merged into the colourless centre. Such at least was the idea; but, unfortunately, the gradation too frequently partook of the character of a series of plainly distinguishable concentric zones forming well-defined steps, as it were, or, in other cases, the softening was of so abrupt a nature as to be undeserving of the name of gradation. Such a vignette was palpably useless for the production of good results, as its inherent faults were altogether beyond remedy.

The more careful class of printers made use of various kinds of masks perforated with apertures, usually with serrated or broken edges, and these were placed at a distance from the negative in order to soften the light as much as possible, without allowing it to spread too far, and tissue paper or ground glass was frequently employed in addition, to cause still further diffusion. With such aids as these there was scope for the exercise of a great deal of skill, for, while one operator might make but a bungling job of it, another would with the same implements secure results of the highest excellence. But the perfection of vignetting so far as we know it, we may say the ideal, was only reached when the printing frame was kept in constant motion during the period of printing. Some operators would at intervals alter the position of the frame, turning it upside down, then on one side, then the other, imagining that they thus attained a better gradation; but this was in the majority of cases not so, though greater symmetry of the vignetted portion might result. What was required was a constant and regular motion obtained by suspending the printing frame or frames from an ordinary roasting jack, or similar contrivance, so that the edge of the aperture in the mask was constantly casting its shadow, however soft, in a different direction, and so materially aiding in the softness and evenness of the gradation. We have seen vignettes printed in this manner in the sun, without tissue paper to diffuse its rays, that have been almost perfect in their gradation.

These methods, of course, require considerable modification in order to adapt them to the purposes of the enlarger. The vignette glass for his purpose is out of the question as, setting on one side the faults of gradation, unless it were made from optically worked glass, the loss of definition it would cause would suffice to condemn it. The perforated mask with serrated or even plain opening is, however, quite available, and this is the method generally adopted, though the position of the mask in relation to the negative is very different. Instead of being placed at a short distance in front of the negative, it takes a position between the latter and the print, and at a considerable distance from either, the precise position being immaterial provided it is not near enough to the lens to come within range of its focus, or sufficiently close to the print to cast a sharp or perceptible line. Further than this, it is kept in motion during the exposure in order to secure greater softness, the movement being in the line of the axis of the lens, though some operators prefer an up-and-down and side-to-side or circular motion.

Whatever the direction of the motion may be, it cannot be regular in the strictest sense, since it is made by hand, the operator holding the mask in his hand during the exposure. Now, not only is this a tedious business, especially if the exposure be long, but it requires great steadiness, as well as patience, to perform it even fairly well; and even then there is no guarantee that it is applied evenly, or that it is properly centered; for it must be borne in mind that there is no guide to the effect being produced, and the mask may be unconsciously moved some inches right or left, up or down, during the exposure, which is certainly not conducive to uniformity or symmetry. Still, in careful hands, very satisfactory results accrue, though it is our impression that much better might be attained with proper appliances.

It is surprising to us that no attempt seems to have been made, or, at any rate, published, to render the working of the vignetting mask automatic. We ourselves long ago experienced the irksomeness of the hand manipulation, and have from time to time made various attempts to improve upon it. The first of these consisted in mounting the mask upon a sort of easel running on a tramway, along which it might be worked by means of a rack and pinion. This had at least the advantage that the strain was taken off the attention of having to keep the mask centered, but it still had to be worked by hand, and there was no guarantee that it was worked evenly, so that, though portions of the gradation might be smooth enough, others might be abrupt, from stoppage of the machine at some particular point.

Next we tried substituting for the rack and pinion by which the easel was actuated a heavily weighted pendulum, working underneath it, and imparting to it a to-and-fro motion. This was so far a gain that it dispensed altogether with hand work, and the motion was also regular; but, while the mechanism was comparatively complicated, its action was anything but satisfactory, and the movement of the screen was jerky and uncertain, and, moreover, a very heavy weight was necessary to overcome "the traction" of the tramway.

But we recognised the pendulum principle as the correct one, for, in addition to its being automatic and regular, it in itself assists in softening the gradation, since, as each successive beat becomes shorter, the vignetter travels over a constantly decreasing space, so that, in addition to the softness gained by the alteration of position, we have also the softening arising from a gradually decreasing exposure from the centre outwards.

We eventually settled upon a method on this principle, which, while extremely simple, is as nearly perfect in action as could be desired. Discarding altogether the clumsy tramway, we made the pendulum itself carry the vignette, or, in other words, the vignetter forms a portion of the pendulum. This, in our case, works from a fixed point near the ceiling; but it would be a decided advantage to have it work in a movable frame running on castors, or, at any rate, capable of being shifted if required. The pendulum itself consists of a stiff rectangular frame nine feet long and eighteen inches broad,

the top and bottom (or short sides) being of wood, and the remainder light iron rods. The width is desirable to give it a firm bearing on its pivots and to ensure its running in the direct line of the axis of the lens. The mask itself is attached to the side rods, and is made adjustable as regards height.

This arrangement is fixed about midway between the average positions of the lens and easel; as a rule, we work but two or three sizes, but, where a wide range has to be covered, the movable pendulum frame is desirable. The exact position of the mask and its opening are easily found when the pendulum is still by raising or lowering it until the desired effect is obtained on the screen; or, if a special opening be required for a particular negative, the mask itself may be utilised as a focussing screen, and the shape of the aperture sketched thereon. In this manner it is easy to make masks for stopping out single figures from groups, or for printing in clouds to landscapes; in the latter case both sky and foreground may be covered as desired, and the two blended one into the other in a manner scarcely possible by other means.

THE DECOMPOSITION OF HYPO.

A PAPER of great interest to photographers was read at a recent meeting of the Chemical Society, the subject being the changes undergone by "hypo" when in an acid condition. The exact title was *The Change proceeding in an Acidified Solution of Sodium Thiosulphate when the Products are retained within the System*. A number of glass bulbs were filled with solutions of hypo acidified with an equivalent quantity of acid, and placed in a bath at a fixed temperature, and at certain definite times after the acidification the contents of the bulb were titrated with iodine solution; and, among other checks upon the result, the acidity was determined soon after the iodine titration. It is not necessary here to give details of the experiment, the more especially as we shall, in all probability, return to the subject at some future time. As to the results (using the old term, hypo, for brevity), the author (Mr. A. Colfax, B.A., Ph.D.) concludes that the change, when the products, viz., sulphurous acid and sulphur, are retained in the system is a reversible one, a limit being reached a certain time from the time of acidification. The value of this limit is affected by (1) state of concentration, (2) ratio of the mass of acid relative to the hypo, (3) the nature of the acidifying acid, (4) the temperature. Sulphurous acid cannot prevent the decomposition of thiosulphuric acid. The presence of both products of the change in the system seems essential for the attainment of a limit value; for sulphurous acid, when initially present in the system at the time of acidification, has but small effect upon the values expressing the extent of chemical change. A higher temperature favours the interaction of sulphurous acid and hydrogen or hypo, a secondary change which proceeds at lower temperatures with extreme slowness. When this paper is published *in extenso*, we may probably print it in full, as it treats upon a subject upon which, at present, we have very little definite knowledge.

It will be observed that the plan, which is continually increasing in favour, of adding acid sulphite of soda, is not involved in the consideration of the question, and the belief in the absence of change in hypo after such addition is in all probability correct. Certainly no observations of ill effects have been published up to the present time.

But at the same meeting two other papers were read which had a bearing upon the evil effects of acid hypo. All practical photographers are familiar with the dark-coloured deposits appearing in hypo solutions that have been used to fix prints or negatives, and it is no difficult matter to imagine that somewhat similar deposits, invisible to the eye, may be present in photographs fixed in "hypo," and may lead to their fading. The classic researches of Messrs. Davanne and Girard showed that an insoluble colourless silver thiosulphate, gradually decomposing in time, would be so produced when the fixation was carried on in a limited quantity of hypo, but we now refer to further products. Mr. Harold Picton showed that in some so-called solutions of metallic sulphides the microscope revealed the fact that the whole of the sulphides present existed in the form of very finely divided particles, and the same gentleman, in conjunction with Mr. S. E. Linder, advanced what they considered a good *primâ facie* case for the belief that there is a continuous series of grades of solution passing without break from suspension to crystallisable solution. They hold that in the lowest grades of solution a certain loose attraction exists between the particles and the molecules of the solvent. They describe a new property, which seems to hold for a large range of solutions extending from suspension to crystallisable solution.

During the interesting discussion that followed it was mentioned that the microscope had enabled particles of silver nitroprusside, so small as the one-hundred-thousandth of an inch in diameter, to be detected in what was apparently a solution. Mr. Picton's paper stated that the sulphide of mercury he had examined in a so-called solution exhibited small particles under the microscope which were not diffusible even in the absence of a membrane. What is more probable than that the decomposition of the silver salts by hypo in either an albumen or gelatine film, gives rise to insoluble silver salts which would not diffuse by osmotic action, and would therefore remain in the film for future evil? The rate of diffusion in such films would be far slower than in a collodion film; hence, if the production of these hypothetical insoluble products occupied an appreciable time, it might be predicated that in a collodion film the producing salts would diffuse into the outer liquid, in which the precipitation would then take place, while in the case of gelatine or albumen the slower diffusion would retain some of the salts long enough to permit the decomposition and lodging *in situ* of harmful products other than those described by Messrs. Davanne and Girard. The speculation is fraught with interest.

The Originator of the Gelatine Process.—In reference to Mr. W. B. Bolton's article on this subject in our last issue, we have received a long letter from a Mr. J. Faulkner of a highly polemical nature. The interference of Mr. Faulkner in this controversy is clearly not that of a directly interested person having a prescriptive claim to be heard, and we therefore do not publish his letter. It appears to be written in the interests of Mr. J. Burgess. We are at all times glad to give those who are criticised in our columns an opportunity of replying, and we shall be willing to publish a letter from Mr. Burgess himself. There are only two points in Mr. Faulkner's communication which we shall notice. Mr. Faulkner casts doubts on negatives ever having been produced by Maddox's formula. Let him read Mr. W. E. Debenham's testimony to the contrary, given at the meeting of the London and Provincial Photographic Association on December 4, and let him also read Mr. W. Adams' letter in our present issue. He asks how Mr. Bolton knew that the Jury of the Inventions Exhibition awarded a medal to Maddox without dreaming of Burgess? We answer, Simply because Mr. Bolton himself was one of the jurors on that occasion.

The New Methylated Spirit.—Writing to the *Chemical News*, on this subject, Dr. B. C. Waller says:—'There already exists

one way whereby users of methylated spirit may still obtain it unadulterated with paraffin. Apply to the supervisor of the district for permission to purchase the spirit in quantity direct from the manufacturers. The applicant will be required to specify the objects for which he proposes to use the spirit, and his statement and application will go to head-quarters. After the usual business of red tape and circumlocution, it will probably be allowed, and the applicant will then be required to find one surety in a bond for 200*l.* as a safeguard against the application of the spirit to any improper uses. For this bond five shillings is charged. After these formalities are complied with, the holder of the permission is supplied with forms of requisition, and can order direct from the distillers. He also becomes a "user" of the spirit within the meaning of the recent order, and is entitled to requisition supplies free from paraffin.

"A Mischievous Innovation."—"An eminent medical organ learns that in future half per cent. of *wood naphtha* (*sic!*) is to be added to methylated spirit," says the editor of the journal above referred to. "Our contemporary imagines that the mixture will be 'absolutely undrinkable,' which is a mistake. He is aware that the new concoction will be unwelcome to photographers and others, but he thinks that in such a case their complaints should be disregarded. We hold, on the contrary, that an injury to research and to the organic chemical manufactures will be poorly compensated by a hindrance thrown in the way of a few desperate drunkards. It is not too much to say that the Act permitting the sale of methylated spirits is completely stultified by this most mischievous innovation."

Run on a Portrait.—Since the betrothal of the late Duke of Clarence and Avondale was announced, there has been a great demand for the portraits of the Royal pair. But when the illness took a serious form the demand became very much greater. On the day after the death, one London house alone, that happened to possess negatives, we are informed, received orders for many thousand prints, the retail stationers being all cleared out, and were taking orders for future execution. In such cases as this, it seems to be a pity that photo-mechanical work is not more largely utilised than it is. To get several thousand silver prints from a few negatives at this season of the year occupies a considerable time, during which period the passing excitement is abating. With Woodburytype or collotype a few days will suffice to supply all demands. Great as has been the demand for the portraits of the Royal Duke, it is doubtful if the sale in the aggregate has been so great as it would have been had he lived to be married.

Post-mortem Photography.—*Apropos* of the fleeting interest in portraits of deceased persons, those who have had much professional experience in post-mortem photography are fully aware of the expediency of supplying the proofs and obtaining payment as quickly as possible. If this be delayed until after the funeral, it is rarely that the photographs are considered satisfactory, whereas, had they been delivered before that event, they would have pleased. So it is with enlarged portraits of deceased persons. If the picture be delivered promptly, it generally gives satisfaction. But if the work be kept, as some photographers keep it, a month or two in hand, the probabilities are that it will be more severely criticised than would otherwise have been the case. Imaginary faults are discovered by friends, for which there may be no grounds, and unnecessary trouble in alterations, often to the deterioration of the picture, have to be made.

Xylonite in Photography.—Last week we suggested a modified method of working the carbon process so as to avoid the different transfer operations. This was to spread the pigmented gelatine on thin transparent sheets of xylonite or celluloid and then print the picture through this film, as was done with the transparent media used in the earliest days, and before xylonite could be obtained in such a high state of perfection as it can at the present time. Here is another use to which xylonite in connexion with carbon printing may be probably very profitably put. "Porcelains" of the scrap type, made by the carbon process, have had a considerable run during the last few years, but the trade in them is on the wane. One of the reasons for this is that, with an accumulation of them, there is no convenient way of preserving or displaying them, also their fragile character. Xylonite can now be had with exactly the appearance of opal glass, of any tint, or with a grain so like ivory that it can scarcely be distinguished from that material. Now, it is quite as easy to develop a carbon picture on xylonite as it is on opal glass, and the former substance would cost considerably less. A carbon picture on opalescent xylonite or celluloid cannot be distinguished in appearance from one on opal glass, while with the ivory grain it looks much superior. Furthermore, such pictures can be placed in albums, like ordinary ones, on card-mounts, and transmitted through the post without danger of breakage. Here is manifestly a novelty for those who choose to take it up. But we do hope, if it is, that the "cutting prices" of porcelains will never be adopted.

Printing of the Future.—The general consensus of opinion amongst practical photographers is that albumenised paper is now meeting the most formidable rival it has ever had, in gelatino-chloride printing-out paper. On several occasions, when fresh printing processes have been introduced, the knell of albumen has been said to have been rung. Yet it still survives, and is, as yet, the most popular process of the day, and the one most extensively used commercially. There is, doubtless, a big future for the new paper, but albumen will die slowly, we strongly suspect, notwithstanding all that is predicted.

The Price of Platinum.—The metal is now quoted at 2*l.* 2*s.* 6*d.* per ounce. But a short time ago it was nearly double this price.

The Daily Press and Technical Matters.—We have several times of late commented upon the blunders made, and the nonsense written, by some of the daily press when they touch upon photographic subjects. This ignorance is not confined to photography alone, but applies to technical matters generally. *Lightning*, last week referring to electrical matters, says, "How utterly idiotic are the lucubrations of the ordinary pressman when he essays to deal with things he is ignorant of."

Process Work.—The *Daily Graphic* of Friday last is an excellent example of the services that photography renders to illustrated journals and also of some of its short-comings. One of the illustrations depicts a scene in the City occurring in the afternoon of the previous day. But for photography this would have been next to an impossibility in the time. Such things, however, are now daily accomplished by the "photo-zinco" or analogous processes. The number of the paper also contains two half-tone illustrations, one a portrait of the late Duke of Clarence and the other of the Princess Victoria of Teck. These two illustrations, though the blocks themselves are really good, show that they are not well suited for rapid printing in the ordinary way with type. The *Daily Graphic* possesses the most perfect machinery for quick printing of a high quality, consequently we may fairly assume the blocks were used under the best conditions circumstances would allow. We had a large number of the impressions through our hands, and the most striking feature was their inequality. Of some there was nothing to complain, while others were mere smudges. A noteworthy fact was, that although in some copies the half-tone prints were bad, the line blocks in them were equally as good as they were in the best. It is clear that a process that will yield half-tone blocks that can be successfully printed under ordinary conditions with type, on a rapid machine, is still a desideratum.

Mr. Chapman Jones's Lecture.—It is a pity that no more than twelve or thirteen persons attended Mr. Chapman Jones's lecture at the Photographic Society of Great Britain on Tuesday night. The subject, *The Distortion of Outline in Photography*, has perhaps not much of the ring of fascination in it; but it is undeniably one in which every one who takes, or attempts to take, photographs is

directly interested. Mr. Jones's discourse was clear, practical, and not at all above the comprehension of those for whom it was intended, and we regret that the exigencies of space oblige us only to give the briefest possible report of it. Mr. Jones's suggestions as to the use of single lenses in preference to rapid rectilinears when photographing from nature, and his method of testing the curvilinear distortion of such lenses, deserve attention.

ON THINGS IN GENERAL.

Is it permitted to hope that Mr. Newman's paper on *Some Recent Exhibitions*, that was read before the London and Provincial Photographic Association the other day, will lead to some reforms in exhibition matters, though its talented writer is evidently a novice at "judging?" That reform is needed goes without saying, as the French put it; but there are so many interests concerned, so many pet theories held up by Judges, so much indecision as to what should and what should not be allowed, and, above all, so few people among even the experts who have really the courage of their opinions that it cannot but be felt the hope, if any, is of a very pale cast. But the rider to the Report of the Judges of the Pall Mall show may lead to the amelioration of one most glaring evil—the want of discretion shown by hangers on occasion. It needs no argument to prove that the hanger's post is a most difficult and onerous one to fill. But the duties of judging at the many important exhibitions, added to the immense labour of selecting and seeing to the hanging of a large number of pictures—and how laborious and time-consuming such work is none but the experienced have any conception of—occupy too much time to enable us to expect that it can be often taken by the comparatively few men that are suitable for the office. There is great want of backbone shown so far by hangers in general, or, what is worse, most improper favouritism. It cannot be doubted that we have too many exhibitions, and, now that a central representation of the many societies in the country seems to be within measurable distance of realisation, I would ask if a central body could not be chosen to deal with the ethics and practice of exhibiting, to formulate rules for their conduct, and not to give their sanction to any exhibition not carried out under the rules they would frame. Exhibitions might be held under the "Affiliated Societies'" rules, and at once awards so obtained would become of known value, and appreciated by the public at large after no great lapse of time. If such a dream should become true, it is to be hoped that the hideous term "Challenge Class" should be replaced by one less reeking of the shambles and kennel.

The paper read by Mr. Dallmeyer, at the Patent Society, *On Reflections and Refractions*, appears likely to mark an era in optical construction. With the vast strides made of late years in optical methods on dioptric lines, there would not appear to be valid reasons why catoptrics should not be pressed into the service of the lens-maker. We all know why a parabolic curve is given to mirrors for optical use, and why they are not available practically for lens-grinding; but there is now such a range of power put into the hands of the lens-maker, owing to the great variety of dispersion and refraction at command in modern optical glass, that it is reasonable to expect that lens-mirrors with spherical curves could be constructed that should be of considerable utility for each of the purposes named at the discussion that followed the reading of the paper. Of course, to get the full value of the new principle, it would have to be remembered that, for photographic purposes, there would be a very practical limitation of size. The picture producible would always have to be considerably smaller than the diameter of the lens-mirror employed, and a very little knowledge of the art of lenses would indicate the probable price of such an instrument capable of taking a picture not larger than an optical lantern slide. That such pictures would possess a crispness and a richness superior to one taken by an ordinary lens is almost certain, as most, if not all, of the reflection would be got rid of. True, a large "camera" would be needed, as, of course, a conical hood, surrounded by a cylindrical one, all covered by black velvet, would be needed to keep out stray light, and the optical portion would need to be scrupulously clean. *Cui bono?* may be asked; the reply is given at once.

That the patent agent's "life is not a happy one" might certainly be believed from reading two only of the patents, the specifications of which appear in this JOURNAL for January 15. I have carefully read three times over the wording about the transferring photographs patent, but, after such close perusal, I am as much in the dark as before I commenced the task. What the original instructions could have been to allow of no clearer description than is here given is a great mystery. The few gleams of meaning that come to me at times suggest that Herren Zahn and Schwarz have patented something that does not differ in principle from the Autotype Company's "temporary support," and the manner of using it. But this patent is clearness itself compared with Herr Eugen Hakh's. It consists of a method of photographing under a "bound light" in a "revoluble housing," consisting of "trapezium-shaped" surfaces, formed of fabric on frames adjustably arranged at angles to each other, said housing having adjustable light funnel, platform, and stool, and being provided with suitable means for attaching to the camera, &c. Is it possible that we have here some modification of the Lafayette camera stand?

RATIO OF GRADATION.

YOUR review of Messrs. Hurter & Driffield's ingenious if over-refined "Actinograph" reminds me that one of the most important conclusions to which those gentlemen's photo-chemical investigations have given rise has not been taken into consideration by photo-experimentalists and investigators to the extent it deserves, and has also so far remained a dead letter to the ordinary photographer, who consequently believes and maintains the exact contrary. I allude to the theory that the ratio of gradation in a negative or a positive are unalterable by development.

If I understand Messrs. Hurter & Driffield aright, a photographer may, by varying the constituents of his developing solution, alter the printing value of his negative—that is, assuming a correct exposure, he can produce a very thin or a very dense negative at pleasure. But those gentlemen maintain that the photographer's power is strictly limited to this. He cannot by any known combination of developing reagents alter the relative gradations of his negatives. In the case of the thin image, the ratio of the half-tones to the high lights is, we will suppose, as 1:2, that is to say, by measurement the density or opacity of those portions of the negative may be quantitatively expressed in those proportions. Now, it may here be argued that, as a dense image can be developed up from the same exposure (let us suppose a correctly exposed plate has been cut in two for the purposes of the experiment), therefore the ratio of gradation, or density as it is sometimes called, has also been altered. Is this so?

According to Messrs. Hurter & Driffield, it is not by any means the case. They contend (and their experiments bear out the contention) that the ratios of the dense half of the plate are the same as those of the thin negative, and that, upon measurement of the former, the half-tones and high lights stand towards each other, in point of density, in exactly the same proportions as those of the thin half. In the one case they are as 1:2, in the other as 2:4; from which it will be observed that the ratios are, in fact, unaltered.

It appears to me that this theory will not be easily demolished. The idea that photographers are, and have been, able to influence the relative gradations of their negatives with a given developer rests upon a misapprehension. They can only influence their printing values—that is to say, they may change 1:2 to 2:4, or 4:8, or 8:16; in fact, make them dense or thin as they may require; but to produce 1:3 or 2:5—that is, reduce or increase the relative opacity of a certain part of a negative at will, by bringing up the half-tones, and without also proportionally adding to the density of the shadows, is, I think, a proposition that no longer holds good, and, in point of fact, never did.

For, if that proposition could be sustained, it would be equivalent to holding that the developer is discriminating in its action, reducing some parts of an exposed picture and not attacking others. I do not see how any one can regard this as tenable, and yet it is practically what we have all been doing for a great many years past. To my mind, Messrs. Hurter & Driffield's teaching on this point comes to this, that the inter-relations of the effects of exposure upon a sensitive film cannot possibly be altered by the developer. Whether the re-

sulting negatives be thin or dense, the ratios of gradation are always the same, and that it is the light, and light only, which fixes those ratios for us, which the developer is impotent to alter.

As I have hinted, I do not see how this teaching can be negatived except it be argued that a developer has the remarkable property of ignoring parts of an exposed plate at will. In my view and my experience this does not characterise any developer in modern use, and I therefore cannot understand how Messrs. Hurter & Driffield are to be dislodged from their position, that the ratios of gradation in a negative are determined by the exposure.

JAMES R. HOPWOOD, PH.D.

CONTINENTAL NOTES AND NEWS.

Jarret's Teleo-photo Lens.—At the meeting of the Société d'Etudes Photographiques on December 24, M. Jarret, *apropos* of an article in the *Moniteur*, reminded the members that, before Mr. Dallmeyer had dealt with the same subject, he (M. Jarret) had already presented to the Société d'Etudes Photographiques, in October, 1890, an optical combination for taking photographs at a great distance, permitting of a degree of magnification of from thirty to sixty times. On that occasion he showed a number of pictures taken with the objective in question, and M. Jarret now asked that mention of these facts should be made in the Society's report. He also read a letter from M. Toublan, President of the Nantes Photographic Society, certifying that the objective had been in the last exhibition of that Society, where its merits had been recognised.

Restoring Faded Manuscripts.—To restore faded manuscripts, so that they may be more easily photographed, Herr Liesegang recommends passing them through a weak bath of ammonium sulphide

Aquarelle by Daguerre.—M. Thouronde, of the Société Française, noticing among some works of art an aquarelle signed "Daguerre," purchased it, and, to be assured of its authenticity, submitted it to critical examination, as a result of which he became certain that it was a genuine work by this father of photography.

Use for Green Glass.—We read that from a very thin negative a vigorous one may be made by the following plan:—Take a positive by contact from the original weak negative, the light being allowed to pass through green glass, and then a second from the positive, the illumination being again allowed to filter through the coloured glass. Weak development to commence with, followed by a more energetic solution, is recommended.

New Magnesium Powder.—MM. Boichant and Mairet, on January 8, presented the French Photographic Society with a number of fine pictures, obtained by means of an illuminant resulting from the combustion of a powder of their own composition. The pictures were said to be much superior to those generally obtained in this manner. MM. Boichant and Mairet are experimenting with a view to compounding a magnesium powder which does not emit smoke.

M. Lippmann's Experiments.—At the Conservatoire des Arts et Métiers in Paris, and in presence of a numerous audience, M. Lippmann recently discoursed on photography in colours. We are told that, when he threw on the screen a coloured image of the spectrum which he had obtained, there was great applause, which was renewed when he explained that the success of his method proved that he had compelled the light to produce, by means of gelatino-bromide, plates of silver so thin that they were transparent. The colours of the pictures were due to the same causes as the colours on soap bubbles. The comparison is not a good one.

Spanish Dry Plates.—English dry-plate manufacturers will be interested, if hardly pleased, to know that an establishment for the manufacture of dry plates is about to be opened at Barcelona. Native photographers, and patriotically minded Spaniards generally, are said to have long deplored the fact that the "extrangero" should have possessed what is to all intents and purposes a monopoly of the dry-plate trade in Spain, and so at length somebody, with the necessary confidence in his own powers, and, of course (at least, we hope), the necessary amount of capital to back it up, has determined to contest the market with the English and German manufacturers.

International Photographic Exhibition in Paris.—Under the patronage of several of the Ministries an International Exhibition of Photography and its allied industries will be held in Paris, at the Palais de Beaux Arts, from April to September next. It will comprise four principal sections, embracing Historical and Scientific Photography, Amateur and Professional Photography, Applied Photography, and Photographic Apparatus, &c. These principal sections will be subdivided as occasion may determine. M. Attunt-Tailfer, of the Chambre Syndicale des Fabricants et Négociants de Produits et Appareils Photographiques, is President of the Exhibition, M. F. Guelpa being Commissaire-général.

Mercury-silver Development Process.—According to a French contemporary, positive prints may be made by development in the following manner. Paper is first floated on a solution of twenty parts of mercuric chloride in 500 parts of distilled water, and, after drying and washing, is sensitised with five parts of silver nitrate in fifty of distilled water. The paper is exposed (presumably to daylight, but we are not told) under a negative for from twelve seconds to a minute, and the image is developed on a bath consisting of ferrous sulphate one part, vinegar (? acetic acid) one part, distilled water thirty parts, washing and fixing taking place as usual. Of the making of printing processes there is, apparently, no end.

Chronophotography.—The *Revue Generale des Sciences Pures et Appliquées* publishes a lengthy paper, by M. Marey, descriptive of his new method for analysing movements in physical and natural science. Accompanying the memoir, which is divided into eleven chapters, are about fifty illustrations of the apparatus M. Marey employs, together with many remarkably curious phases of movement of men walking, jumping, leaping, and running, horses galloping, breaking waves, and the gyrations of various common "objects of the seashore," herons, ducks, pigeons, flies, &c. M. Marey's paper is probably the longest devoted to this fascinating subject which has appeared in a periodical. *Nature* the other week contained extracts from it, but the paper should be read in its entirety and studied in conjunction with the whole of the illustrations.

Photography and War.—The Franco-Prussian War was a godsend to the French artists, who to this day have never ceased finding themes for their brushes among the incidents of that terrible contest. In a lesser degree one notices the same feeling (possibly sustained by purely commercial instinct) among photographers, whose reproductions of battle pictures are only more numerous than the latter themselves. In the current number of *L'Héliochromie* there is a collotype reproduction of Lebœuf's picture of *Combat sur la Place* (nuit du 18 Octobre, 1870), depicting a bloody contest between two handfuls of Frenchmen and Germans in the corner of a square. The French seem to be getting the worst of it. Is it in order to assuage his readers' regret and mortification at this that the Editor also presents them with a reproduction of the Pantheon picture of *Jeanne d'Arc victorieuse rentre à Orleáns?*

ART? FINE ART? OR WHAT?

[Read before the Dundee and East of Scotland Photographic Association.]

I AM well aware that to not a few the subject I have chosen will be somewhat uninteresting. I think, however, that in our society we deal too exclusively with practical matters, and I am not prepared to admit that such a question as I would discuss is of little or no moment to even the most practical of men. This subject takes one over con-

siderable ground, and involves such questions as "the relation of photography to fine art," naturalistic photography, and the like, and it is only proper that we in Dundee here should devote an hour to the consideration of questions which have mildly excited the photographic world for some little time past.

Altogether apart, however, from these questions it is surely a good thing to discuss the proper sphere of photography, its possibilities or impossibilities, so that, if nothing else be gained, we may at least raise the average standard of work by agreeing what not to attempt.

I know there are some who believe that already all things are possible to photography except the rendering of nature in her own tints. I am sorry that I cannot side with these optimists. I think photography one of the most wonderful things that the genius of man has devised, but I also think that its purposes are in a sense limited. In the very nature of things this must be so, for if we argue for its unfailing truth we cannot at the same time claim that it can idealise the one attribute excludes the other. This limits, either in the one direction or the other, its possibilities in the graphic arts, although this is not always admitted, or, if admitted, absurd attempts are sometimes made to get over the difficulty by sacrificing its truth, in the expectation that idealism may to some extent be introduced, which it is not.

With these few introductory remarks, let us consider in what relation photography stands to *art* or *fine art*, and, having determined this, it will be one step towards determining its legitimate sphere. There are few expressions more difficult of precise definition than the expression "fine art." Some imagine that it has to do with the beautiful. It may, or it may not. Some confound "fine art" with "good taste." It has no relation to good taste. One man considers fine art to be the power of reproducing with great faithfulness what nature has cast around him. Another declares that art is *not* nature, and has no necessary connexion with it. So on it goes, some even going to the length of holding that "fine art" is in the artist only, and that pictures, poems, statues, or music, are not fine art at all, but mere gross expressions of it. In such a labyrinth, one begins to wonder if it is given to man to understand what "fine art" is, or if he must wait patiently for the time when all things shall be revealed. After an extremely boisterous and devious passage, I have steered my ship into what appears to me to be a kind of haven of rest, at least in the meantime, and as one other idea more or less cannot be more than as a drop in the bucket (already I admit over-brimming), I shall proceed with my argument. Since the word *fine* seems to me to be a mere qualification of *art*, a kind of subdivision, so to speak, I shall first try to determine what *art* is, and having determined this, proceed to consider what makes it *fine* art.

Art is a word of very wide significance. It may be the the art of a rider, a wrestler, or for that matter of it the art of a shoemaker. Art is the faculty of getting the greatest possible result out of the least possible means, and the apparent disproportion between the cause and effect is what we measure, admire, and denominate *art*. There may be much or little of it, but the essential meaning of the word is this faculty which enables one man to overtake what another, not so gifted, cannot, although to all appearance equally fit. For example, a strong man and a weak man are in a boat. The weak man is an accomplished rower, while his stronger companion is not. Notwithstanding this, the boat turns in a circle, propelled by the skilful stroke of the weak man; this is the result of his art, and just as the result of his rowing is out of proportion to his mere strength, so is his art greater or less. What we admire and call art here is the *apparent disproportion between the cause and the effect*. Without this *art* the weak man would only pull (as others would) in direct proportion to his strength, he would be overcome by his stronger companion, and we should see nothing to admire or wonder at.

Let us take another example. A forest of trees has to be represented in a picture, and, as in the former case, we contrast two men, one with a certain amount of art, the other without, or, at any rate, with less art than his competitor. After hours, days, or weeks, the "no art" man having laboriously added leaf after leaf at the expense of infinite time and trouble completes his work, while his accomplished companion having no stronger an arm, no better brushes, and no better paint, gives you the effect of a great forest with half an hour's work of his artful hand. Not only so, but the effect being equally good (we shall say), we see nothing to admire in the one case because we could have done as well ourselves in the same length of time, but in the other we wonder at and admire the art which with a few magic touches saves hours of weary drudgery. Now, here again you will notice that what we call art is the *apparent disproportion between the means employed and the end obtained*.

Art is the outcome of experience, and has nothing to do with a man's genius, save that a man of genius acquires art more quickly, and to a higher degree than a stupid person. It has nothing to do with his feelings, ideas, or conceptions, but merely with his power to learn. Do not imagine that my argument intends to prove that much labour necessarily means little art. If the results are so much the grander, so that there still is *the apparent disproportion between the means and end*, the same result is obtained. One sometimes hears the would-be critic wax eloquent in his denunciation over what he calls the "finican" work of certain of our great artists—"it is laboured;" "it is not clever;" "there is no dash in it." This is not the question. The question is:—Is there not, after all the labour, such a disproportion between the means and end as to prove the artist to be possessed of the highest art—never mind the labour, is the result not yet out of all proportion to it?

This is my conception of *art*, and we may now proceed to discuss the further question of what *fine art* is.

After the somewhat elaborate discussion of the term art, it will take only a few sentences to determine what *fine art* is. The very term suggests that it deals with the higher part of man's nature.

It is difficult to define such expressions as "feeling" and "emotion." Fortunately, we all know what is meant by these terms. When we stand before a fine picture, a piece of sculpture, or listen to good music, we are more or less moved; we cannot tell why, but we know to what extent. It is not the mere workmanship, so to speak, that we admire, for a poorly painted picture will sometimes touch the chord against another actually much better done from a technical point of view. We listen perfectly unmoved to a certain air played, perhaps, in a faultless way, while another air strummed carelessly on a worn-out instrument touches us immediately. It is not the association of ideas, for we may never have heard either of them before. Why, then, this difference? Only this, that in the one case the composer had the *fine art* faculty, and was able *to produce emotional results out of proportion to the apparent means*, while the other had not.

It goes without saying that before another can make us feel he must first feel himself, but equal sympathy being admitted, one will have *fine art* enough to give you his whole heart, while another communicates far less. He feels as much, he has not the *fine art* faculty, and although he may have *art* enough to paint a picture or compose a piece of music, it is dead and lifeless, because of the want.

What do we admire in "The Cotter's Saturday Night," or Tennyson's "In Memoriam?" Not, certainly, the mere rhyming, but we wonder at and admire the intense emotional effect produced by causes so apparently inadequate, that we fail to grasp them altogether. This is *fine art*.

Just as in a painted picture, there may be much labour or little labour, the fine art has nothing to do with this; but, is the emotional effect out of proportion to the labour spent in expressing it?

As we have to do chiefly with pictures, let us see, in order to clear up matters a little, what the precise steps are through which it goes from first to last. First, then, the artist sees and feels the effect he would convey; secondly, *his fine art* suggests his conception for the canvas; and thirdly, his art or craft enables him to put his conception into actual shape.

I insist on the middle stage. It is, so to speak, the message he has for his fellow creatures; the *art*, or third stage, is merely the ink and paper, and aims at nothing more than the expression of the artist's idea.

Man is not a copying machine like a camera. When he paints a picture he does not copy from nature as a camera does; he paints *his conception* of what he sees, and his conception is necessarily what he himself has felt as well as seen; it is, in short, the sum total of his sensations so far as he can convey them, and the extent to which he can convey them is the extent of his *fine art* faculty, plus his art faculty.

To recapitulate. We recognise *art* when the *tangible* results seem to us far beyond what could have been expected from the simple means, and we recognise *fine art* when the *emotional* results seem to us far beyond what could have been expected from the simple means, the disproportion in both cases indicating the *amount* of art or fine art, as the case may be.

Many people confound the beauty or power of the artist's conception with "fine art." They hold that, according to the artist's intensity of emotion so is he endowed with the faculty of "fine art." This is not my idea. I hold that fine art has nothing whatever to do with the intensity or beauty of the artist's conceptions, but only with their *expression*. Fine art is not called into existence until the artist seeks to express his emotions in some tangible shape or form, and then he shows his "fine art" by the craft, cunning, or skill with which he transfers his emotions to the hearts of others.

In what relation does photography stand to all this?

Beginning modestly, we may first determine if photography is an art or a science. The term art-science is one very frequently applied to photography, but I am convinced that if it be an art in any shape or form it is so only in a very restricted way.

Admit, for argument's sake, that a photograph reproduces with a fidelity far beyond anything that the hand of man could attain to, it must still be allowed that the means used to attain this end are infinitely more complicated than the few hairs tied on a stick which the artist uses. Indeed, it might be argued that if *art* is the apparent disproportion between means and end, photography is not art at all, but science. There is no art on the part of the lens when it produces its images; it does so strictly in accordance with natural laws. The developer acts as thoughtlessly as any other chemical experiment, and these are the chief factors in every photograph. It is true, you have one small part to play—you must have the *art* of exposing properly; but even here a few shillings will purchase for you a machine to do even this. I do not admit art in development. Art in development is only called in when the exposure has been made without art. And as I have already allowed art in exposure, I cannot allow it here again. With such an infinitessimal part of the picture the outcome of art, is it honest to call a photograph a work of art? I think it may be doubted.

I am dealing now with mere photographic productions, independent of subject, which will be considered next; I therefore take no cognisance of the selection of views which comes in under the *fine-art* aspect. Allow me, then, to repeat that at every step in the production of a photograph, the *means* are apparently, and, of course, actually equal to the *ends*, and there is no room for *art* in the strictest sense of the term; that is, of course, according to my definition of the word art. If, then, photography be not an *art*, it can scarcely be a *fine art;* but not to terminate the discussion by this logical quibble, let us consider the subject at greater length.

It is a favourite explanation to say that camera and plates are to the photographer just what the paint and brushes are to the painter, and that, therefore, the photographer is on an equality with the painter. Admitting, for argument sake, that the premises are correct, the conclusion does not follow, for merely the very simplicity of the artist's means, and the end he obtains from them, entitle him to an infinitely higher platform than the photographer. But I hold that the camera and plates are not the equivalents of the brush and colours.

I will admit the parallelism, if you will allow me to say that the camera and plates are the brushes and the colours only when nature herself is the artist. The picture painted by the artist is a transcript of his own emotions, but a photograph is not a reflex of human emotions at all, unless, indeed, accidentally so, but is a direct reproduction of nature, and only through science the offspring of man's genius.

But, it may be argued, does not a photograph awaken emotions just as a picture by any other method does, and is this not enough to stamp it a work of fine art? By no means. I allow that it may awaken emotions, but so also does nature herself, and she is not art or fine art. It does not follow that because a photograph looks like a work of fine art, or gives rise to similar sensations in the mind, that it is a work of fine art. The manufacture of paste gems has got to that stage of perfection that it is difficult even for the expert to tell the true from the false—this does not convert the paste into the real for all that. The same is true of photography. I quite admit that a few photographic giants have turned out work marvellous in itself, and marvellously like the creations of the painter, but after all it is only simulation, and nothing more.

If, then, photographs are not works of fine art, are they all equally bad or good from an art point of view, for this would seem to be the outcome of this argument. By no means, for even denying them the title of fine art in its true essential meaning, it is not to be denied that the general character of a man's photographic work does indicate whether or no he has the feeling of a true artist in him.

When one is face to face with the work of our photographic "dons," the first thought that strikes him is this, that in the author of this or that picture there are the makings of an artist, and that, given the necessary craft with the pencil or brush, works of fine art in every sense of the term would be the outcome. My position, then, is, that photographs may, to some extent, show the art proclivities of the photographer, yet they are themselves not works of *fine art.*

In conclusion a few words may be said on the naturalistic or "out of focus" idea and its relation to the points we have been discussing, what is sought to be obtained by these dodges, and are they generally successful? The idea from the first was to bring the photograph into a closer similitude with the work of the artist. It is a tacit acknowledgment that the artist attains the effects of nature by some other method than slavishly copying nature, for the photograph slavishly (so to speak) copies nature, and photographers would fain improve on this. An exact reproduction of nature, the size of any ordinary picture, would not be effective, in so far as the elaboration of detail *on this small scale* detracts from the general effect. If a picture or design is to be effective as a whole, it must be simple, or, at any rate, the broad, general effect must predominate over the various parts.

Artists call this quality "breadth," and it is to obtain this quality that the "out-of-focus" school suggests the obliteration of a certain amount of detail by putting the picture to some extent out of focus. Now note that even if this dodge were successful (which I deny) it would in no way alter the *fine art* qualifications of a photograph; but, being a purely technical manœuvre, it would, to some extent, introduce *art* or *craft* into its production, that is, if you can dignify the racking in or out of your lens by such a term. But I deny that to put the picture (to the limited extent it is possible) out of focus is to improve its breath, and for this reason, it is not so much a superabundance of detail that destroys the breadth of a photograph as the confused and muddled light and shade.

In order to gain this quality of breadth the artist introduces a scheme of light and shade for the picture *as a whole.* This part is not copied from nature, but is ingeniously devised by the artist to produce the effect of nature on a diminutive scale. The success depends upon the perfection of his *art* or *craft.* This is an entirely different thing from the results brought about by racking the lens out of focus, for, according to my notion, this only makes confusion worse confounded by leaving untouched the muddled light and shade, while at the same time you remove the *raison d'être* of it.

Detail does not *necessarily* destroy breadth, for if it is not unnaturally obtrusive it should be invisible at the correct distance for judging of the breadth of a picture. What we want in photography is the power, not to suppress detail, but to simplify the scheme of light and shade, making the effect of each part subservient to the whole. As the confusion of black and white in a photograph is due, in great part, to the erroneous rendering of colours, it follows that orthochromatic work must possess more "breadth" than the ordinary; at any rate, it must be truer to nature. For all this, I hold, as I have already said, that the broad light and shade introduced into a picture by an artist is a creature of his ingenuity; and, while it is meant to represent nature, it is not copied from nature, for he must fall upon some plan of his own, whereby miles may be represented by inches, and perfect relief by a flat surface. The perfection to which he attains is the measure of his *art* or *craft.* I do not myself see how breadth of effect is to be introduced into our photographic productions save by the stereoscope, which has a wonderful effect in unravelling the tangle; but, since the stereoscope is only of service for small work, which least of all requires breadth, the difficulty remains.

To put a photograph out of focus, and leave it otherwise untouched, I am convinced, is to make bad worse; still, it is an honest endeavour to overcome a recognised failing, and ought not, I think, to be laughed at, but rather to be honestly argued on, and taken or rejected by the result.

J. K. Tulloch, M.B.

THE PHOTOGRAPHIC SOCIETY'S LECTURES.—II.

Mr. H. Chapman Jones on "The Distortion of Outline in Photography."

On Tuesday evening last, January 19, Mr. William England took the chair on the occasion of Mr. Chapman Jones delivering the second of the Society's lectures, the subject being *The Distortion of Outline in Photography.*

After saying that there would always be differences of opinion as to what was true in the pictorial representation of solid objects, Mr. Jones went on to point out that distortion was either due to the lens or the sensitive surface. Distortion by the lens might be due simply to the lens itself or its position, and the same definition applied to the plate. It was sometimes said that distortion was due to the camera, but it could only indirectly be produced thereby. Having fully described the causes of barrel and cushion-shaped distortion, and illustrated the effects of the two kinds of curvilinearity on a series of concentric circles, he mentioned that he had found that, by taking negatives of a rod affixed to a wall, and having a number of marks upon it at equal distances from each other, the crowding or expansion of the divisions at the edge of the plates showed the extent of distortion given by a particular lens. In this case he found that a seven-inch single lens covered a five-inch plate —that is, a quarter-plate—without any measurable distortion. In this

way, one could obtain a permanent record of the distorting effects of any lens.

The lecturer illustrated distortion due to the lens by references to the remarkable effects sometimes produced in portraiture by placing the objective too near the sitter. This kind of distortion was, he said, due to the application of an exaggerated principle. They had all seen pictures in which the feet of a sitting figure were nearly large enough to hide the figure. This was undoubtedly distortion, although the necessities of plane perspective were entirely present. As regards distortion due to the plate, its very flatness led to distortion, as spheres placed towards the edges of the pictures became enlarged. On the other hand, curved plates got rid of this distortion to some extent; but then the spheres on the outer edges became much smaller than those in the centre, and thus the cure was worse than the disease.

Mr. Jones showed that the position of the plate, if it be tipped backwards or forwards, produced false gradation of the scale and elongation of the image, and also pointed out how the use of the swing-back tended to enlarge foreground objects, which was a distortion. Incidentally, he advised the use of a single lens, with the diaphragm placed in front, when photographing from nature, in preference to a rapid rectilinear. If the stop be placed in front of such a lens, the curvilinear distortion produced crowded up part of the image on the plate, while the flatness of the plate tended to lengthen it. He also explained how distortions in a negative could be cured in reproducing the image with the plate or the negative tipped as might be desired from the nature of the distortion, and thought that this utilisation of distortion had never been sufficiently treated of.

A short discussion followed, and at the conclusion Mr. Chapman Jones was heartily thanked.

PRESSURE GAUGES.

[Read before the Manchester Photographic Society.]

There has been considerable discussion the last few weeks regarding the pressure gauges used to indicate the quantity of gas in cylinders, and many questions have been asked as to their safety, although little has been said about the purpose for which they are made—that is, their efficiency and correct registration when in use. I therefore propose to lay before you a brief description of the construction of some of the best gauges, their qualities, and a few remarks on the safety or danger in using them, illustrated by parts in various stages of manufacture, and show the results of carrying tests up to the point of destruction.

The exterior of the ordinary Bourdon type of gauge is well known to all of you, and demands little comment, as we are now more concerned with the interiors. After removing the glass and dial plate, we expose a metal tube shaped like a letter C, the lower end of which is screwed to the boss, which is attached to the cylinder. The boss is bored so as to admit gas direct from the cylinder into the curved tube. (In passing, I may say that steam gauges are constructed on precisely the same principles, but are only adapted for the low pressures common in mills and steamships, which rarely exceed 200 pounds pressure on the square inch in the largest steamships, and a little more than half that in mills.)

The upper end of the C tube, which is closed, is attached to a small lever, which acts on a rack and pinion, causing the movement of the needle on the dial. The general principle of this part of the mechanism is very simple, but the workmanship should be of the finest quality, and in this respect most makers' gauges that I have inspected fail, the loose fittings permitting great inaccuracy.

The action of this form of gauge depends on the fact that, when internal pressure is applied to a curved tube, the tendency is to straighten the tube. If it is thin and flexible, a light pressure is sufficient to make it nearly straight; but, if the tube is made of great rigidity, a very heavy pressure only serves to slightly open the crescent shape. Now, when such a tube as this is filled with a fluid under high pressure, it moves the free end of the bent tube a little, and the rack-work moves the needle a little, increased pressure further expands the crescent, and causes the needle to revolve a greater distance over the dial.

It will be obvious to you that, in order to allow of sufficient expansion, only an elastic material can be used, while, to withstand the enormous pressure of several hundred atmospheres, that material must be of the strongest quality. In saying such plain facts are obvious, I credit you with much greater intelligence than some makers have displayed in the construction of the instruments they have put before the public. I am not going to mention the names of such people, but will show you their work, when you will not be surprised at so-called accidents.

Here is a gauge tube which the workman found to be too rigid to register properly over a sufficient range—probably the substance or texture of the metal is unsuitable for this class of work; I think a sound, honest workman would have rejected it, but this gentleman, whoever he was, took a file and reduced the wall of the tube sufficiently to yield to the required pressure, regardless of the fact that it has weakened the structure, and that he had carefully arranged for what might some day be called an accident. A tube that requires filing should be remorselessly put aside.

Here is another gauge, made for steam pressure, but in this instance the tube is too soft or inelastic, and when expanded it becomes "set," and refused to return to its original shape—that is always a bad sign; the maker in this case, instead of substituting a better tube, has attached a spring to pull the tube back to its original position. This, no doubt, will give a reasonable result for a time on the dial, but it indicates a tube too weak for the pressure it is intended for, and is bad in design, for the necessary resistance should have been obtained by strengthening the tube itself; the life of such a pliable tube depends upon its flexibility only, irrespective of any elastic temper it may possess.

I recently saw a gauge tested that was made by a manufacturer of some repute; the dial was marked up to 300 atmospheres, and, after submitting it to that pressure for five minutes, it only returned to twenty-five atmospheres instead of to zero, showing a "set," and that it had been tested to a point approaching its limit of endurance. Now, what constitutes a sound manufacture, and a reliable form and quality in this vital part of the gauge? The best reply I can give is to describe the process of making these tubes, as carried out by the largest European manufacturers, Messrs. Schaeffer & Budenberg, of this city, who courteously explained their methods to me, and have enabled me to bring tubes in all stages, so that you may see the whole thing, from beginning to end.

First, then, is the material, which for gas is of the finest special selected homogeneous steel. The ordinary Bourdon tube is made of brass alloy. Few makers use steel, but I would only use a brass tube for low pressure, where its strength is relatively great. I consider such gauges are of little practical utility to lanternists, on account of their limited range.

Having obtained a bar of octagonal pressed steel of the requisite length, it is drilled longitudinally, and for a four-inch gauge the bore is about a quarter of an inch in diameter. Every tube is carefully polished inside, and rejected if any scratches or tool marks are visible. Then, if perfect, the outside is turned down, leaving a flange at each end, which is threaded with a screw for coupling to the terminals. By this method the thickness of the wall of the tube is equal throughout, and of equal strength.

Some gauge tubes I have seen are made of drawn tube, soldered to the flange. Here is a dangerous factor to begin with, for the structure of the metal is strained in the drawing, and the thickness is unequal. No doubt the motive is cheapness, with a reliance on the general ignorance of the public; further, a steel which permits of drawing is necessarily of unsuitable quality for this purpose, for the best metal does not permit of drawing at all.

In the tube I am describing the method not only produces equality in thickness, but it places no strain or torsion on the metal beyond the light pressure of the cutting tool, which may be left out of consideration, and it necessitates no heating in that process. The tube is then flattened, so that the section becomes elliptical instead of circular, thereby improving the range of movement, and permitting the employment of a thicker and stronger tube.

The tube is next filled with sand, heated moderately, and bent with the least possible tension into the crescent shape now shown to you; it is very important that the bending should be regular, avoiding angles. After careful tempering it is tested to a very high pressure far beyond the scale shown on the dial. This maker's gas gauges will bear a pressure of 800 to 900 atmos., although cylinders are only filled to 120 to 130 atmos. To satisfy me on this important matter, an ordinary four-inch gauge tube was taken from their stock, which I now show you, and, after repeated tests up to five tons on the square inch, it was decided to burst it in my presence, and I carefully made the following measurements:—

Upon testing to three tons, the gauge expanded $\frac{1}{64}$ of an inch, and, upon removing the pressure, it returned to its original shape. It was tried at four tons, it expanded $\frac{1}{32}$ of an inch, and returned to zero without any sign of set; then a five-ton pressure expanded it to $\frac{1}{16}$ of an inch, and it once more returned to zero without any set, when the pressure was withdrawn. At six tons' pressure it opened $\frac{1}{8}$ of an inch; but, when the pressure was released, it was found to have a set of $\frac{1}{64}$ of an inch. The last trial was to carry on the pressure to the bursting point, which was only arrived at when the pumps registered

7 tons 16 cwts. = 1164½ atmospheres, or, 17,472 lbs. Such a test manifests the immense superiority of well-made steel tubes over the ordinary Bourdon brass alloy gauges, and should satisfy any user.

The testing was hydraulic, and performed slowly. It is a very different thing to suddenly apply a force which acts like a blow of a hammer. If a cylinder valve is opened slowly, the pressure in the gauge is gradually increased; but some persons carelessly open the valve fully and suddenly, and occasionally the gland is screwed so tight that it is impossible to open it gently. In such cases the inrush is said to be equal to about double the pressure when it is applied gently. Now, the ordinary pressure of a full gas cylinder is 120 to 125 atmos., and the best gauges, such as the one possessed by this Society, will register up to 250 atmos. If the gas is turned on at full pressure suddenly without any check valve, it is possible the needle would pass beyond the range of the dial. There would not, however, be any danger of bursting, or even of giving a set to a well-made steel tube such as I have described. It is difficult to get gas into a gauge quick enough to show such extra pressure, and several trials were made with a gauge, from which the check had been taken out, attached to a hundred-foot cylinder containing common air compressed to one hundred atmos. The valve was opened as quickly as possible, but I could not detect any advance of the needle beyond one hundred atmos.

The cause of bursting must be sought either in a thin or badly made tube, such as I now show you, which was burst by a user several months ago, or else it must be found in the introduction of some explosive compound; and it is to the latter I now ask your attention.

Without going deeply into that form of force known as heat, I will remind you that all matter familiar to us contains an amount of it, and if you take, say, ten cubic inches of matter, and suddenly compressed it into five cubic inches, all the heat of the ten cubic inches would remain for a time in the smaller space, and the temperature would be proportionately raised. On the other hand, if you expanded the ten cubic inches into twenty, the temperature would be proportionately reduced, and remain lower until external heat was absorbed. Any of you may prove this latter fact any evening when our lantern is in use, when you will find that, as the gas is consumed and the contents of the cylinder are allowed to expand, the temperature of the cylinder is perceptibly lowered, and it feels cold to the hand even in a warm room. To show the increase of temperature following sudden compressing, I propose to show you an experiment with this small piece of apparatus, kindly lent by Professor Core, of Owens College. It is a tube and piston, something like a child's popgun. If the piston is pressed in slowly, the compressed heat escapes into the tube, but, if it is quickly driven home, there is not time enough for the heat to escape, and the temperature of the compressed air is raised high enough to ignite a small piece of tinder.

Something similar to this occurs when the gas is let into a gauge quickly from a cylinder, for the air already in the gauge tube is suddenly squeezed into one hundred and twentieth part of its normal volume.

Pressure gauges certainly are not furnished with tinder, but if there is anything else in a gauge that easily fires, such as oil, left from improper testing operations, or carried into it from a cylinder valve, it becomes greatly heated, and only requires the introduction of the oxygen to ignite it. Further, if the gauge is employed for both oxygen and coal gas, and there is a residue of one of these in the tube when it is used for the other, we have at once a most explosive compound, at a considerable heat, containing carbonaceous matter, all ready to ignite at a comparatively low temperature, and burn with the greatest rapidity; hence an explosion.

All this became apparent to Mr. W. Morton Jackson, the Manager of the Manchester Oxygen Company, when he directed his attention to it, and I have seen the results of his plucky and somewhat dangerous experiment when investigating the matter. That gentleman devised what I think is a perfect safeguard against the folly of the careless or misfortune of the ill-informed lanternist. And one of the most remarkable points in connexion with the explosion at one of the leading London Photographic Societies a few weeks ago is that such a Society should either be ignorant of, or be content to remain without, an efficient check valve in the gauge used.

In the published account of this explosion it is noticeable that the gauge is particularly singled out for condemnation, although it was not apparently the cause of the incident any more than was the ceiling of the room, both of which were damaged by the explosion. No mention is made of any check valve in the gauge, and it is reasonable to suppose that with one the gauge would have been saved, although the ceiling might still have been damaged by the fractured regulator; for the cause was, doubtless, the combustion of the oil, traces of which were afterwards found in the cylinder valve, whereby some of the metal was fused, and the regulator, whose maker and form are not stated, was destroyed. There was no trace of fire discovered in the gauge at all, it being burst by the violence of the explosion, which also shattered the regulator. It appears to me the explosion did not originate in the gauge, but between it and the cylinder valves, for the necessary heat must have been obtained by the sudden compression of the air outside the cylinder, and not from the oxygen in it, and that the portion of the air that was compressed within the gauge would be heated at its extreme end at the greatest distance from the oily cylinder valve, which extreme end showed no trace of fire; but the portion of air that was compressed between the cylinder valve and the regulator was in the presence of the oily matter, and it was there, I think, that the ignition and fusion were originated.

The lesson to be learnt seems to be the need of great care to use strictly clean apparatus.

The air in the tube between the cylinder valve and the bellows of a duplex regulator appears to be driven into the bellows when the gas is turned on, thus relieving the tube and preventing the accumulation of heat. A similar action may take place with other regulators.

There is no great novelty in the adaptation of check valves to pressure gauges, for they have been supplied by Messrs. Schaeffer & Budenberg for many years; not, however, to guard against the bursting of the tubes, but to prevent the undue wear of the rack work from careless usage in connexion with hydraulic pumps. It was found that the men in some of the packing-houses would overstrain their hydraulic presses; and then, fearing some damage, would let down the pressure suddenly, this tended to wear the rack work and spoil the gauge; therefore a check was introduced which only permitted the escape of the water from the gauge at a diminished rate; but this check is not suitable for gas.

The Jackson Check Valve for compressed gas is simple, and all the better for it, as it is not likely to get out of order, and there is nothing about it to choke the gauge, such as pumice, as mentioned in The British Journal of Photography lately.

The stem of the gauge which is attached to the cylinder has a thread tapped into its bore, into which is screwed a brass plug about a quarter of an inch long, this plug has a hole drilled through it about one-twenty-fifth of an inch in diameter. The exact size is not important. Upon the end of the plug, and filling the stem of the gauge laterally, is placed a piece of felt; on this is placed a little disc of fine wire gauze, then another felt and disc, until altogether there are five thicknesses of felt, separated by four discs of metal gauze. These are all squeezed together by another screw plug similar to the plug first inserted, the result being that, although gas at a low pressure can easily, although slowly, pass into the gauge, high-pressure gas can only enter at about the same slow speed, the heat due to compression has more than abundance of time to escape, and all chance of high temperature, and consequent explosion, is prevented.

This check, so simple and so perfect, can be had at a trifling addition to the cost of the gauge, and no sane person should be without it. I have used my own gauge thus protected without the slightest compunction for both oxygen and coal gases, one immediately after the other, and have never seen either a quick inrush or exit of the gas indicated on the dial.

In The British Journal of Photography of January 8, a safety device is mentioned, made by Mr. Beard, the entrance to the gauge being closed by a screw having a slight passage in the threads, which would prevent any sudden pressure. The brief description is by no means explicit, but it seems to imply the necessity for turning the screw to admit the gas to the gauge after attaching it to the cylinder. If that is so, I think such a device is distinctly inferior to the Jackson Check, inasmuch as with the latter no separate act of the operator is required; and, further, with a single thoroughfare, great care would be needed both to see that it was in order or closed, to begin with, and then to turn it slowly to gradually admit the gas. A reliable check should be always ready for use without special attention, and it should be equally safe and effective in the hands of the careless as well as the cautious operator.

A check valve containing pumice, or any friable substance, should be avoided, for it would be very likely to become imperfect in action by choking the inlet under the high pressure behind it.

H. M. Whitefield.

(To be concluded.)

Messrs. S. & G. de Saulles & Co.'s new trade list contains particulars and prices of the various kinds of glass employed for photographic and microscopic purposes. The firm do not supply amateurs.

RECENT PATENTS.

PATENTS COMPLETED.

MEANS FOR ENLARGING PHOTOGRAPHIC GELATINE FILMS BY THE AID OF CHEMICAL MEANS AND WITHOUT THE AID OF AN ENLARGING APPARATUS.

No. 16,125. ALBERT JOHN EVES HILL, 4, Clifton-villas, Clifton-road, Norbiton, Surrey.—*December* 19, 1891.

THE object of my invention is to provide means whereby photographic gelatine films can be enlarged without the use of enlarging apparatus. I effect this by subjecting the film to the action of a solution in water of citric acid (or other acid of the like nature), glacial acetic acid, hydrofluoric acid, and glycerine.

I assume the film to be operated upon to be mounted upon glass, as is customary. After the photographic picture has been taken, developed, and fixed, it should be well washed to cleanse it from the developing and fixing agents employed.

If ammonia has been used in developing, it is advisable to neutralise it, and this may be effected by immersing the film in a bath of acetate of soda (of, say, one drachm to each ounce of water) for a time, in accordance with the thickness of the gelatine film. If, however, the developer has been a fixed alkali in combination with such agents as pyrogallol, hydroquinone, eikonogen, or ferrous oxalate, this treatment with a neutralising agent is not needed.

The plate or support carrying the film is then (after draining, if the neutralising solution has been used) immersed in the enlarging solution, and, after a time, the film will separate from the plate or support. It is then carefully transferred to water, which may best be done by lifting it out of the solution upon the plate or support which it has just left, and introducing the plate and film into a shallow dish or tray containing water. It should be allowed to remain for a time in this water bath. Usually about fifteen minutes will be sufficient.

The final support of the required size for the enlarged film is then introduced under the film, and the film is lifted out of the water supported upon this final support, which may be opal, glass, paper, canvas, leather, or any other suitable material. The film should then be blown upon to remove liquid and air from between the film and support, and the support and film should then be placed on a level surface, and be allowed to dry slowly at not too high a temperature, the ordinary temperature of the air usually answering best. Should the enlargement not be sufficient, the film may, after drying, be again subjected to the treatment described.

When the film has been dried, and, say, after about twenty-four hours, it should be washed in water, and can then be treated as an ordinary film by being, for instance, retouched, intensified, or toned.

The proportions of ingredients for the enlarging bath which I have found to answer best in practice are—

Hydrofluoric acid	1 part by weight.
Citric acid	4 parts ,,
Glacial acetic acid	1 part ,,
Glycerine	1 ,, ,,
Water	32 parts ,,

Other vegetable acids of the same nature as citric acid may be used, such as oxalic acid, tartaric acid, and the like, but I prefer citric acid.

The hydrofluoric acid acts as a detacher for the film, whilst the citric acid and the glacial acetic acid are the active enlarging agents. I use the two together because glacial acetic acid alone is apt to give objectionable curling or waving of the film, whilst citric acid is not strong enough alone to give such a considerable enlargement as is usually desirable. The glycerine is used simply as a vehicle and preservative. Methylated spirit or other preservative usually employed in photography would, therefore, be an equivalent for the glycerine in the solution.

To prevent the acids from attacking the silver in the film, so as to cause loss of intensity in the picture, I may add to the solution a sulphate of iron or copper, or both. I prefer to use in the solution with the hereinbefore given proportions, four parts by weight of sulphate of iron and one-fifteenth part by weight of sulphate of copper.

The proportions of the ingredients may be varied from those hereinbefore given, it being preferred to make the solution somewhat weaker when the operations are to be carried on in a higher temperature than ordinary, and stronger when the temperature is lower.

Although, for simplicity, I prefer to include the hydrofluoric acid in the bath with the enlarging agents, yet the film may be first put into a solution of hydrofluoric acid, and then, without washing, be subjected to the action of the citric acid and glacial acetic acid solution.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—1. For enlarging photographic gelatine films, the use of hydrofluoric acid, citric acid (or acid of a like nature), and glacial acetic acid, substantially as hereinbefore described. 2. A bath for enlarging photographic films, the said bath being composed of hydrofluoric acid, citric acid, or acid of a like nature, glacial acetic acid, glycerine (or equivalent vehicle or preservative), and water, with or without the addition of an agent for preventing loss of density, substantially as hereinbefore described. 3. A solution for enlarging photographic gelatine films, the said solution being composed of hydrofluoric acid, citric acid, or acid of a like nature, glacial acetic acid, glycerine, and water, in or about the proportions hereinbefore stated, with or without the ingredients for preventing loss of density.

IMPROVEMENTS IN THE CARBON PROCESS OF PHOTOGRAPHIC PRINTING.

No. 18,827. MAX RAPHAEL, Breslau, Prussia.—*December* 19, 1891.

THE object of this invention is to produce carbon-print pictures by a different method than that heretofore adopted—that is to say, without the employment of the customary carbon papers, transfer papers, and compression process, and from a negative directly upon a mica plate prepared with carbon emulsion.

The process heretofore followed in the preparation of carbon pictures is only practised if the picture which was originally taken upon carbon paper, and afterwards sensitised with bichromate of potassium, was subsequently transferred to single or double transfer paper, and from this on to glass or other material. However, in order to effect the transfer, other manipulations have heretofore been necessary.

How much trouble and waste of time have been incurred by the process heretofore followed will be best ascertained by perusal of works of different authors bearing upon the subject.

One of the chief objections to the process heretofore practised is that the picture is produced in a reversed condition after exposure, and the correct picture only obtained by transferring.

By my invention I propose to simplify the above process by pouring the carbon emulsion direct on the mica plate, allowing the same to dry, and afterwards rendering the same sensitive by means of bichromate of potassium, so that on exposure to light the picture upon the negative is seen in its proper aspect.

This is obtained by printing the mica plate reversed—that is to say, the printing is not produced, as heretofore, by placing the sensitised surfaces in contact with each other, but by placing the rear side of the mica plate, or the unprepared surface, upon the face of the negative. An exposure of this description is only possible because the thickness of the mica plate is considerably less than that of glass.

The direct copying of a negative upon a carbonised glass plate is not possible on account of the thickness of the plate, and has not been attempted heretofore, as only imperfect pictures would have resulted.

According to my invention, the entire process of carbon printing will resolve itself into:—

1. The sensitising of the emulsion on mica plates by a bath of bichromate of potash.
2. Placing the sensitised mica plate, with its unprepared surface, upon the prepared surface of the negative when copying.
3. The exposure to light.
4. The development of the picture.
5. The fixing of the picture by alum.

By my process many of the usual operations may be dispensed with.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—The process for the production of carbon prints, consisting in treating mica plates with carbon emulsion, and thereby dispensing with the use of the carbon papers, which have heretofore been necessary, and also with the squeezing operation, substantially as hereinbefore described.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 14,—Mr. A. L. Henderson in the chair.

Before commencing the business of the evening the CHAIRMAN uttered an expression of sympathy with the Royal Family in their recent bereavement. The Duke of Clarence, he believed, was an amateur photographer.

Mr. J. TRAILL TAYLOR thought sympathy should also be extended to the Duke of Teck, who took great interest in photographic matters. Not many months ago he (Mr. Taylor) was present at a gathering having for object the establishment of a British Museum of Photographic Portraits. On that occasion the Duke of Teck presided.

The members present concurred in the Chairman's expressions.

Mr. R. P. DRAGE (the Hon. Secretary) read a letter from Captain Mantell, the Hon. Secretary of the Photographic Society of Great Britain, acknowledging, with pleasure, the receipt of the Association's resolution of support in reference to the action of the Photographic Society of Great Britain in connexion with the late Exhibition.

Mr. J. WERN BROWN said: "Allow me to reply to the question put by Mr. Haddon in my absence three weeks ago as to the grounds upon which I claimed permanency for the toned bromide prints from which the silver had been removed for the production of the chalk-red tones. The question was, no doubt, put under a misapprehension of what I wished to convey to the meeting. I

did not claim permanency for the image as formed according to the latest addition to the toning process, either in the sense taken up by Mr. Haddon or in any other. The solubility of the colour deposit to which he refers has never been in question. My remarks were intended to refer to the known tendency of uranium-intensified negatives to go on increasing in density. A member of the Photographic Club, on the previous evening, had put forward a theory of the probable chemical reactions involved in the toning process, and expressed an opinion that the toned image from which the silver had been removed would be permanent, in the sense that it would not be subject to the same tendency to intensification in course of time as one in which the silver was retained. It was my intention only to convey that opinion to the Association. As regards the difficulty with the hypo suggested by Mr. Haddon, it will be remembered that I recommended for these chalk-red tones that both development and toning should be carried further than would be necessary in ordinary circumstances. This leaves a convenient margin of allowance, and permits of the removal of the hypo without too great reduction. In practice, the print, after removal of the silver, is rinsed for a couple of minutes, immersed for five minutes in the peroxide of hydrogen bath, and again washed for five minutes. Further reduction, if it be required either generally or locally, can be obtained by the use of a very dilute alkali."

Mr. A. HADDON said that when making the remarks referred to he could not understand how the prints, which had only been produced a week or a fortnight, could claim to be permanent. It was only by the test of time they could make sure whether they were permanent or not. With regard to the toning of gelatino-bromide prints by uranium nitrate and potassium ferridcyanide, they noticed that as soon as the image began to tone there was a brown deposit in the solution. This was, undoubtedly, ferrocyanide of uranium, but its place was not in the solution as a precipitate, but in the paper or gelatine. It was due to this waste of uranium that they had to print much beyond what was required to allow for the solubility of the precipitate in washing. He thought they should considerably diminish the quantity of ferridcyanide and increase the quantity of uranium. The reason why there was a red precipitate formed in the solution was because the ferrocyanide of potassium formed finds nothing in the solution to combine with. By diminishing the ferricyanide and increasing the uranium there would be sufficient nitrate of uranium left for the ferridcyanide to combine with. When toning had gone as far as was required, it was necessary to wash the whole of the acetic acid away before fixing. There was a loss of density caused by the alkalinity of ordinary water, which would dissolve uranium ferrocyanide and ultimately cause the image to disappear. Thus it was necessary to allow a sufficient amount of over-printing. But it was possible to remove silver which had been modified into ferrocyanide or chloride by substituting for Farmer's reducer a solution of potassium ferridcyanide and ammonium sulphocyanide. If this were used there would be no necessity for a prolonged washing, and the silver eliminator could be kept acid. If acetic acid in combination with the ferridcyanide and sulphocyanide were used for removing the silver, they would experience no loss of image due to alkali, and the picture would be completed by a rinse in water. This solution would reduce ordinary negatives or bromide prints.

Mr. WEIR BROWN said Mr. Haddon's information was the first practical outcome of his publication of the process. The remarks only applied to its latest development. With the first process the amount of washing required was slight indeed. The suggestion to employ acidulated water for the wash water of the first process was a good one. There would then be no loss of image however prolonged the washing might be.

Mr. HADDON recommended as a suitable uranium toning bath a one per cent. solution of nitrate of uranium in two ounces of water, to which a drachm of acetic acid and two grains of potassium ferridcyanide were added.

Mr. J. S. TEAPE drew attention to a recent great reduction in the price of platinum.

The Chairman exhibited a stereoscopic shutter, the principle of which was that the exposures were made by two revolving metal discs, the apertures of which opened and closed in the centre.

After some further general discussion the meeting adjourned.

Camera Club.—January 14.—Mr. J. Howson read a paper entitled *The Pro and Cons of Chloride Printing.* Captain Abney occupied the chair. Mr. HOWSON argued in favour of the permanence, beauty, and simplicity of working of gelatino-chloride prints, and contended for the special applicability of each printing process to its particular purposes. The lecture was illustrated by a collection of examples, some matt and some highly glazed in surface, the prints also showing the variety of colour attainable. On January 28 a series of lantern slides will be shown, described by Lieut.-Colonel Gale, after which other slides by members will be exhibited.

North London Photographic Society.—January 19, Mr. E. R. Groundwater in the chair.—The *Journal of the Photographic Society of Great Britain* was laid upon the table. A number of packets of bromide paper sent by the Eastman Company for distribution were issued to the members for experiment. Mr. EDGAR CLIFTON then spoke on *The Dark Room*, referring to his own experience with various dark rooms, from the traditional cupboard under the stairs to a distinct room in the house, the various fittings in which were fully described. The window was covered by a frame on which American cloth was strained, and working on a hinge, so that white light might be admitted at any time. The other arrangements were as usual, except that the waste had to be received by a pail, the risk of overflow being met by limiting the water supply accordingly. The need of ventilation was strongly insisted on, and various modes were suggested, the one preferred being by means of the lamp from which light is obtained. Sinks were discussed, and lead-lined ones strongly recommended, failing which, an ordinary washing-tray would be a good substitute, as mentioned by Mr. Cowan. An ingenious plate-washer, consisting of a series of perforated trays, was described. A great advantage in washing plates was to tie a piece of thick felt over the nozzle of the supply tap, as thereby much grit was prevented from reaching the films. A mode of improvising a dark room when travelling was next suggested. Carrying a sheet of waterproof cloth among one's luggage, with a portable lamp, a jug, and two pails, which could always be obtained in one's temporary abode, any plates might be developed in comfort at an ordinary table in the evening. Permanent dark rooms should be coloured orange crome, the light reflected from the walls and ceiling being thus made safe in case of any risk of light leakage. A word of advice followed to keep the hypo dish where it can be conveniently found, but out of the way of everything else—under the sink, on a shelf, being a good place. For dishes, Mr. CLIFTON preferred ebonite, and would always use an automatic rocker when possible. The draining rack being touched open, a sketch was given of a useful form. Outdoor dark rooms were described with illustrations (the black-board being freely used) showing modes of construction, arrangement, and ventilation, and also provision for daylight enlarging. On the question of lighting, one thickness of yellow glass and two thicknesses of yellow fabric were spoken of as giving a safe light under most conditions, artificial light being best, as being of constant power as compared with the variations of daylight. For isochromatic plates a piece of red fabric should be added, and in all cases the light, if possible, should be screened from the eyes.

Holborn Camera Club.—January 15, Mr. A. J. Golding in the chair.—Mr. JOHN HOWSON gave a lecture on *Isochromatic Photography.* [This will appear in a future number].

Lantern Society.—January 11.—Captain GLADSTONE, R.N., read a paper entitled *Westminster Abbey*, illustrated by forty slides, entirely his own work. He began by describing, with the aid of a map, the position of the Abbey and of the various ecclesiastical buildings which in former times surrounded it, pointing out, at the same time, the modern names of the old sites, which in many instances had reference to buildings which have long since disappeared. He next showed a plan of the Abbey, in which the age of each part could be distinguished by the character of the shading. The slides of the exterior and interior were next shown, the lecturer pointing out in each case all that was of historical, architectural, and archæological interest. It will be needless to dwell upon the excellency of the pictures, as every one who knows anything of Captain Gladstone's work is aware of its uniform technical finish and artistic merit. But one of the special features of the lecture was Captain Gladstone's intimate acquaintance with the details of ecclesiastical architecture, which enabled him to trace every variety of style in the ancient and complex structure of the Abbey. Thus he showed in one of the slides that within the space of two feet there could be seen examples of three successive styles of architecture, executed by three different kings—viz., Henry III., Henry V., and Henry VII. And to this he added an almost equally full knowledge of all the history and archæology connected with the building. One amusing fact he noted by the way was that the familiar phrase of "Robbing Peter to pay Paul" had its origin not in the history of the great apostles, but in the story of our two great City churches—St. Peter's Abbey at Westminster having been shorn of much of its revennes to swell those of St. Paul. It is also interesting and instructive to note that the only tomb in Westminster destroyed by the Puritans was that of the only Puritan king, Edward VI.

Putney Photographic Society.—January 13, Dr. W. J. Shepperd in the chair.—The series of lectures on *Photography* in connexion with this Society was ably opened by Mr. W. D. Welford with a paper on *The Camera and its Parts.* Whilst reminding his audience of the natural difficulty of the subject, Mr. WELFORD carefully traced the camera from its early simplicity to its present high-class perfection, pointing out the uses, and in many cases the abuses, of its various parts, and the recent improvements, notably in the matter of dark slides, and the reduction in weight of every part by the use of careful workmanship, light woods, and aluminium. As a general rule, he could not recommend the use of the delicate instruments now so much to the fore, his inclination being towards the medium-priced, but stronger and plainer apparatus. Mr. Samuel, representing Mr. Hudson, was in attendance, and, by means of his new "Kohn" magnesium lamps, a successful group of the meeting was obtained. The second lecture—*Hand Cameras*—on the 30th inst., will be by Mr. A. R. Dresser.

Birkenhead Photographic Association.—January 14.—Mr. George E. Thompson, on leaving the chair in favour of Mr. G. A. Carruthers (the new President), was accorded a hearty vote of thanks for the way in which he had piloted the Society through the past year. Mr. J. A. FORREST then proceeded to discuss the new "Rodinal" developer, and showed some excellent negatives he had produced with its aid. Mr. F. Hope-Jones exhibited the Incandescent Gas Light Company's new aero-carbon light, which has been spoken of as a possible rival of the limelight. Judging, however, from the results obtained, there does not appear to be any immediate prospect of this. The greater part of the evening was most enjoyably spent with Mr. A. W. BEER in his delightful *Camera Wanderings*, 1890. The quality of Mr. Beer's slides is excellent, and much surprise was expressed at the large amount of artistic work which this photographer turns out in a single year.

Birmingham Photographic Society.—January 14, Mr. W. J Harrison in the chair.—The SECRETARY read extracts from the circular received from Mr. Andrew Pringle, asking for the favourable consideration of the members for the fund for Dr. R. L. Maddox. The claim of Dr. Maddox on dry-plate workers was gracefully urged by the President. An important demonstration and paper was then given by Mr. GEORGE BANKART on *Carbon Printing.* [This will appear in a future number]. The dry workmanlike skill and results of Mr. Bankart were much appreciated by some thirty-six members, and a most cordial vote of thanks was given him. The PRESIDENT suggested a joint excursion in the summer months with the Leicester Society, and Mr. BANKART assured the members that his Society would welcome the idea.

Derby Photographic Society.—January 12.—Mr. Keene presided.—Mr. G. BANKART gave a demonstration of carbon printing. The SECRETARY then read the annual report and balance-sheet for 1891, which showed the Society to be in a very flourishing condition, Six new members were elected.

Leicester and Leicestershire Photographic Society.—January 13, Mr Pierpoint in the chair.—The Treasurer (Mr. Wilson) presented his report showing a balance in favour of the Society. Mr. Pierpoint was elected President for the ensuing year. Mr. Porritt was elected Vice-President.

Manchester Photographic Society.—January 14, Mr. Abel Heywood, jun., in the chair.—Mr. W. Thomson, F.C.S., showed a very simple, yet ingenious, device for producing the flashlight. This consisted of one or more tobacco-pipes (common clays), with a ring of asbestos fibre encircling the bowls, the stems being connected by rubber tubing to a mouthpiece. The magnesium powder is placed in the bowls, the asbestos saturated with methylated spirit, and lighted. A sharp puff through the tubing blows the powder through the spirit flame, which completely consumes it, and produces a very brilliant flash. The pipes may be either held in the hand or fixed in suitable stands as required. Cotton wick or cotton waste can be used in place of the asbestos, but, of course, are not so durable. The flash produced was considered highly satisfactory, and the arrangement for producing it was much admired from its simplicity. Mr. Brothers showed a focussing screen which he had used for the "parallactic" method of focussing, similar to the description in the JOURNAL of the 8th inst., but in place of troublesome cross wires, fine pencil lines, diagonally and in squares made on the ground-glass, being used. The glass is made transparent at suitable points by affixing thereto small micro cover glasses with Canada balsam. The eyepiece is first focussed on the ground surface, and is then ready for focussing the image at the transparent spots. The PRESIDENT read a short paper on *Gas Cylinders*, in which he described the precautions taken to ensure safety in their use. These are many, and, as far as Manchester supply was concerned, he felt sure the risk was very slight; but still there was the chance that, in the hands of unscrupulous workmen or dealers, these precautions might be neglected, and he thought that, as the lives of so many depended on the proper observance of the regulations for the safe use of highly compressed gases, it would be wise to petition Parliament to make the observance of such precautions obligatory on all handling these danger-charged reservoirs, and on every one also who sells them. It was decided that a suggestion of Mr. Heywood's, *re* legislation on the subject, should be remitted to the Council for consideration and, if necessary, action. Mr. WHITEFIELD contributed a paper on *Gauge Explosions* [see page 57]. Mr. WHITEFIELD acknowledged his indebtedness to Mr. Badenberg (Messrs. Schaeffer & Budenberg) for much information and a number of specimens of gauges in all stages of construction, as well as a number of defective ones, that had been collected by the firm. Mr. BUDENBERG was present, and spoke highly of the paper. He considered that if the gauges were fitted with a check-valve, and constructed of proper and sound materials, accidents would be unknown. He stated that gauges had been constructed to test up to thirty tons per square inch, so that the ordinary compressed gas was nothing out of the way as regards pressure gauging. Mr. MORTON JACKSON considered that accidents have been caused by the *sudden* pressure igniting some carbonaceous matter in the gauge or connexions, and all, or nearly all, had happened in oxygen cylinders. He stated that the presence of oil in compressed oxygen would not cause ignition or explosion without a greater heat than that of the atmosphere (that was proved), and that he did not see any reason for any explosion if the oil was in the presence of a mixture of oxygen and coal gas, but in that latter condition he was not aware of any experiments having been made.

Oxford Photographic Society.—January 5, Mr. E. A. Ryman-Hall in the chair.—Mr. C. C. COLE read a short paper on *Exposure and Development of Plates*. This Society has now been affiliated to the Photographic Society of Great Britain.

Edinburgh Photographic Society.—January 13.—In accordance with previous notice, Dr. DRINKWATER proposed that it was expedient at once to make an attempt to secure suitable premises for the Society, which could be used as club-rooms, &c., and authorise the Council to make the necessary preliminary inquiries and report at next meeting of the Society. In urging the adoption of this motion the Doctor stated that, while they had abundance of members, the Society was suffering from a want of active life, a thing his proposal would go far to remedy. He further pointed out that the Photographic Convention would hold its annual meetings in this city in the summer of this year, 1892, and he wished that body, while here, to have a good opinion of Scottish hospitality, and to show that the Edinburgh Society was a power in the photographic world. Being at present without rooms of their own, such as club, meeting, and dark rooms, with all the necessary photographic conveniences, this was at present impossible. Mr. AYTON seconded the motion, which, after full consideration of the difficulties in the way, was ultimately agreed upon.

Edinburgh University Photographic Society.—January 11.—DR. J. R. PATERSON took the leading part in a very wide reaching and discursive series of remarks descriptive of photographic processes and apparatus. The latter division of the subject embraced the most recent forms of cameras, lenses, stands, slides, shutters, trays, washer, printing frames, and the other paraphernalia of practical photographic work, which were each introduced and explained by the Doctor; and, as evidenced by the questions and short discussions to which they gave rise, showed that the valuable suggestions and hints were fully appreciated by the members. The best method of washing for negatives and positives was fully entered into, the through current and intermittent or alternating method being fully discussed, the latter, as being at once the most perfect and the least wasteful of water, being considered as the quickest and best. At the end of the discourse and discussion, Mr. F. D. Todd was asked to explain his new flash lamp—the Todd-Forret—which he proceeded to do, showing, first, examples of the work done by its agency, which included single full-plate heads, groups of the *genre* class of from two to six or seven figures, which were much admired. The lamp Mr. Todd described as consisting of three parts: 1st, a chamber for the magnesium powder large enough to hold at least one ounce of the material; 2nd, the lamp proper, which rested on the cork, closing the powder reservoir, and communicating with the latter by a metal tube; 3rd, an indiarubber bellows, similar to that used for spray producing, but larger and stronger, being of sufficient capacity to secure a blast of a quarter of a minute if necessary. The duration of the current is regulated by means of a spring clip, which compresses the delivery tube of the bellows at the will of the operator. In working it, the chamber is filled with magnesium powder, and the associated tank filled with methylated spirits of wine, the bellows or bladder with atmospheric air. On opening the clip and pressing the bellows, the air is forced through the powder, carrying the latter with it. At the exit the discharging tube assumes the shape of a thin slit, about an inch and a half across, so that, when the powder enters the ignited spirit in a very thin, broad film, it gives a high and broad sheet of flame, stated to be between three and four hundred inches in area. The action was shown, and the resulting light was most luminous and intense. At the suggestion of the inventor, an oxygen cylinder was attached to the lamps under the impression that an improved luminosity would be gained; but the result was disappointing, the area of the flame being much reduced, and concentrated at the very orifice of the discharging tube. Further demonstration, showed that the flame could be used as one instantaneous flash, which might be continued or repeated at will.

Dundee and East of Scotland Photographic Association.—January 14, Mr. G. G. Maclaren in the chair.—After routine business, Dr. J. K. TULLOCH: read a paper entitled, *Art, Fine Art or What?* [see page 54], which gave rise to an animated and lengthened discussion.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

THE TELESCOPIC-PHOTOGRAPHIC LENS.

To the EDITOR.

SIR,—Your editorial comment is no reply at all to the main points at issue. To those who have studied theoretical optics your remarks anent the form of the negative lens amount to nothing more than a quibble. Were it not that you introduce new matter in this comment (a style of tactics you have used in controversy with me on another occasion), I should have left it unnoticed.

You infer a slur on my patent agents; they, however, have done their duty, and find that the construction of the photographic lens I recently introduced is new. You, sir, concur in describing the Galilean telescope as "a non-photographic instrument!" It is essential in the construction of this photographic lens that the focus of the negative element be some fractional portion of the positive element (quite a new feature in photographic lenses), and, therefore, may permit of its use as an improperly corrected Galilean telescope, should the separation of the two elements be small enough when the instrument is "racked home," or the lenses at their minimum separation.

Why I should be challenged on the validity of a patent by the Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY can be best explained by himself.

The next part of new matter has reference to the "small" camera for the new lens, shown at the Camera Club. Feeble is this in the extreme, and with what intent such a remark, Mr. Editor? Was not the object shown, a lamp-flame, for comparison of *size* with that of an ordinary "long-focus" lens, and that alone? Why not, in a straightforward manner, make reference to the negatives exhibited on that occasion, and say truly that "our old Galilean telescope" could not, of course, compare with the performance of the new photographic lens, in that the principle of its construction as a telescope, both chromatically and as regards the passage of the rays, is entirely different?

I have always hitherto had reason to regard the "Correspondence" columns of your paper as a medium for fair play, but never for advertisement. I am proud of being a "practical manufacturing optician," but, as such, never expected, in these columns, to have reference made to "commercial success." I venture to think, in all honesty, that the snub is not deserved. "Our Editorial Table" in THE BRITISH JOURNAL OF PHOTOGRAPHY is usually supposed to be the place for trade notices.—I am, yours, &c.,

THOMAS R. DALLMEYER.

25, *Newman-street, W.*

P.S.—In your book, just published, entitled *The Optics of Photography*, when referring to "Dallmeyer's teleo-photo objective," by whose authority, may I ask, do you state "the field capable of being sharply covered is limited?" I should further like to state that I have not been directing my "attention to the Galilean method of forming an image, so as to adapt it for photographic purposes," a view, however, that seems best to suit your purposes.

T. R. D.

[We are rather at a loss to know what the main points at issue are unless they are these, that Mr. Dallmeyer, upon introducing his teleo-photo lens to the Camera Club, was taken by surprise, and not unnaturally chagrined to learn that another lens, formed on the same principle as his, and doing the same kind of work, had been introduced eighteen years ago under circumstances sufficiently public, although not under the same name as that adopted by him. The opera-glass telescope was not made expressly for photographing with, but it did its photographic work well, and it is a mere quibble to say that, because its original intent was otherwise, it has no *locus standi* as a photographic instrument. Does Mr. Dallmeyer for a moment imagine that photographs cannot be taken unless with instruments specially constructed for photographic purposes? If so what does he say concerning several charming pictures in the last Pall Mall Exhibition by Mr. Maskell taken by a spectacle glass, which was also shown attached to one of them? What of

the singularly beautiful pictures of Russell Manners Gordon (Count Torre Bella), which in former times were the delight of the *cognoscenti*, and which, on the authority of Mr. T. R. Dallmeyer's father, we know were made by the object glass of a triple lens opera glass? Is he unaware of the fact that nine-tenths of our best optical lanterns are fitted with Petzval portrait lenses, which were made for quite another purpose, but which are generally conceded to serve their present purpose well enough? And does he not think that this may also apply, as it does, to the opera glass? His new lens may be an improvement upon it in this respect, and we have no doubt it will be; but, if the essential feature in its construction be that "the focus of the negative element be some fractional portion of the positive element," then is this condition fulfilled in every opera glass.

That Mr. Dallmeyer's patent agent did not find the prior publication of this application of the opera glass is not to be greatly wondered at, as the search for prior publication by agents is usually confined to what has been previously patented. Those conversant with patents will smile at the acceptance of the dictum or opinion of a patent agent relative to the actual novelty or validity of a patent; but we do not here raise, nor have we raised, any question as to the validity of Mr. Dallmeyer's patent, and this for the simple reason that we do not know what he *has* patented.

The intent of our remark about the small camera to which Mr. Dallmeyer had his lens affixed is this: He seems to have made a point of the fact, as stated by us, that our opera glass gave a sharp image only in the centre of the field of a twelve-inch ground glass, such sharpness, we stated, being confined to a few inches around the centre. Why we said that the new lens did no more was deduced from the facts (1) that, when examining the lamp flame in Mr. Dallmeyer's office on his ground glass, we slightly rotated the frame containing the ground glass, and found the image to disappear at no great distance from the centre; (2) that such specimens of the work of the lens as were shown us by Mr. Dallmeyer did not exceed quarter-plate size; (3) that his subsequent exhibition camera was small; and, finally, that when lenses of not large diameter are mounted in a somewhat long tube, and this at no great distance from the ground glass, it is not possible that a large area can be covered. Even the mammoth Lick telescope has its covering power confined to the relatively small area of five inches!

The chief issue at stake is, we conceive: Has Mr. Dallmeyer been anticipated in the introduction of the teleo-objective or not? If he has, of what value is its claim to novelty, much less to protection by patent? Mr. Dallmeyer does not accept with the best grace possible the fact that we ourselves described fully and clearly enough an objective producing similar pictures to his own eighteen years ago. This perhaps is excusable. We can also understand his disinclination to allow Dr. Miethe priority in the application of the idea. But what can he say to the statement of M. Jarret, a French optician, who, in October, 1890, as will be seen in our "Continental Notes," publicly exhibited to a French society "an optical combination for taking photographs at a great distance," and also showed a number of pictures produced by it? This objective was certified to have been subsequently placed in the public exhibition of the Nantes Photographic Society. With this we leave Mr. Dallmeyer to cling to or reject the valuable opinion of his patent agents that the construction of the photographic lens he recently introduced is "new"—"new," that is, in the sense which would conform to Mr. Dallmeyer's own wishes.

In the concluding paragraph of the letter we are accused in one breath of both advertising and snubbing Mr. Dallmeyer! We are sure Mr. Dallmeyer will bear with us if we do not go beyond this amusing collocation of charges for ample evidence to establish the complete absurdity of both, whether taken singly or collectively. At the same time we tender him our acknowledgments for so kindly instructing us in the conduct of the various departments of the JOURNAL, an attention which by this time he must have perceived we are endeavouring to reciprocate.—ED.].

THE ORIGINATOR OF THE GELATINE PROCESS.

To the EDITOR.

SIR,—If facts are wanted to prove that Dr. Maddox, in or about the year 1871, did make negatives of an emulsion which he, at that period, informed me was a combination of *silver and gelatine poured upon a plate and dried* before exposure, I am *quite prepared to affirm before any committee that he did.* I have not communicated with the Doctor for years, and quite thought he was dead. I am pleased, however, to hear he is still in the land of the living, and, if raising my voice on his behalf will do him any good, I shall be only too pleased to be interviewed by any editor who doubts his statements. Hard words prove nothing. If those who are trying to blacken the good Doctor's name knew him, their railings would cease. I sent to the *Photographic News*, on December 22nd, a long description of the Doctor's transactions with me, but suppose they had other letters of more importance to put in.

I wrote to the Doctor upon the subject some years ago, and, if he still has that letter in his possession, I shall be only to pleased for him to publish any portion of it he feels inclined. I have not a copy of the letter, and do not remember its contents, but the facts there alluded to are extremely vivid upon my recollection. I can distinctly see the bottle of emulsion the Doctor placed into my hands, also the negatives and his instructions for preparing the plates.

I must regret I never properly tried the process, so cannot say if the emulsion supplied to me was capable of producing the negative shown me by the Doctor, but I can *positively vouch* that they were not collodion, and that they had the general characteristics of the present gelatine dry-plate negatives, and far superior to thousands produced by our amateur friends of to-day. Of course, I am not in a position to say no one produced pictures on a gelatine dry plate before the date I speak of. If there is such a one, let him come forward, and I will drop the Doctor's cause, for I am a lover of justice.—I am, yours, &c., WALTON ADAMS.

Reading.

TYLAR'S FILTER.

To the EDITOR.

SIR,—What is a novelty? This question I ask myself on reading your description of the convenient little filter which you describe and give a wood-cut in your last impression. Allow me once more to testify to its merits. I have had them in use for about ten years; I purchased them for one shilling each at an indiarubber depôt in Gracechurch-street. I made a slight alteration, which has its advantages, viz., to place a piece of rubber tubing at the opposite end, so that it can be fixed either end on the tap—consequently *self-cleansing*. Any one who cannot purchase one readily may make one out of a piece of tubing, preferably glass, place a small piece of sponge in the pipe, then some coarse charcoal, then another piece of sponge, a couple of inches of rubber piping at each end, and the filter is complete.—I am, yours, &c., A. L. HENDERSON.

OXYGEN CYLINDERS.

To the EDITOR.

SIR,—I have just read a letter in last week's issue from Mr. W. Morton Jackson in reply to Mr. Seet, and though I have not seen the letter of Mr. Seet, I gather that he has been complaining of the "ill-advised" recommendation of the jury on the Ilkeston affair in favour of gas cylinders.

Mr. Jackson, in defending the recommendation of the jury, brings my name in as influencing the jury by my statement that I had discarded gas bags in favour of gas cylinders. Now, I may say that directly after giving my opinion at the inquest—telling the jury exactly how the accident had occurred—I left the court, and took the next train for home, so that what transpired after I had left I know very little about, except the verdict; and, strange as it may seem, I have never yet seen any report of the inquest, except a condensed and slightly inaccurate one which was published in one of our Manchester papers, to which I replied.

Of course, it is quite correct that I did tell the jury I had discarded gas bags in favour of gas cylinders, and it was no use to supplement this statement with any further remarks, because the jury were a body of gentlemen totally unacquainted with such things, and could have been influenced one way or the other.

Mr. Jackson, in his own interests, representing the Manchester Oxygen Company, naturally said all he could in favour of the things in which he was commercially interested, and as naturally would damn everything else. But, if somebody had told all that could be said about gas cylinders, &c., the jury might have been influenced the other way, or, at any rate, to a modified recommendation or conclusion, so that, all things considered, I don't see that this recommendation of an unscientific jury placed in such circumstances can have the slightest weight, and therefore may be entirely disregarded.

We have, from time to time, been told of the precautions observed by one or more of the Gas Compression Companies for the safety of the users, a good deal of which I have the best reasons to doubt; but there are, in England, many separate and distinct firms who supply compressed gas and the appliances connected therewith—for instance, we have the compression companies in Manchester, and there are several in London—and, so long as we have the unrestricted commercial element, competition, I maintain there is not much chance for absolute safety to the public. Cylinders, gauges, and regulators are now offered at prices from 20*s.* to more than twice the sum for apparently the same thing, or intended for the same purpose, and how are the public to know the difference? Why, in hundreds of cases, they do not know anything but what the dealer likes to tell to tell them.

Oxygen and coal gas are cheap enough now, goodness knows, and for my own part I would prefer to pay even double the price, in whatever form, or for use with whatever appliances will ensure the greatest safety

But, having gone over this ground so often, I again assert my opinion—based upon facts, and a knowledge of what I am talking about—that we shall never be safe under the present system or systems (or want of system) until a Government inquiry and supervision is insisted upon; and, if this matter could be taken up, as I have previously suggested, by such practical men as Sir Henry E. Roscoe, M.P., and Mr. Wm. Mather, M.P., with a committee of not necessarily politicians, or professors, or lanternists, but practical engineers, then the public confidence might be restored, and it might be discovered that the present system was defective.—I am, yours, &c.,

W. L. CRADWICK.

Manchester, January 18, 1892.

DRY COLLODION POSITIVES.

To the EDITOR.

SIR,—In the early days of gelatine as a vehicle for bromide of silver, I spent most of my spare time experimenting with the then known photographic processes. I not only rang the changes of the thousand-and-one processes, but followed ideas of my own. It seemed to me, from what I heard and what I experienced, that some direct positive process was no only necessary but attainable, and I tried gelatine emulsion on paper, iron plates, wood, &c. I then tried in the same manner collodion emulsion, and with all I met with sufficient success to encourage my going on. A few of the ferrotype collodion emulsion positives I have preserved, and they still retain all their first colour and gradations. Just when I might have brought the thing to a successful issue, I found my ordinary business pursuits demanded more instead of less attention, so I packed up my apparatus, and did not look at them again until about two years since. Having at the last-named period time on my hands, I again returned to my old love of photographic research. I found it somewhat difficult to recall my ideas in matters of detail, and have been obliged to wade through a deal to recover lost ground, but my great difficulty has been to get a suitable gun-cotton. In the former time mentioned I had a cotton that was readily dissolved, and I could get a clear collodion with ten grains to the ounce of solvents; whose make it was I cannot say, but I have been unable to get anything like it since. However, I can now get a good sensitive collodion emulsion that gives a very good positive on a ferrotype plate. It seems to me that ferrous oxalate is the best developer for ferrotype positives, but recently I have compounded another developer that brings out the image quicker and with good colour. What is wanted with ferrotype positives is a good white light in which to expose. Unless you have this it is hardly possible to secure a pleasant picture. I have exposed under a transparency by gaslight, and also lamplight, and obtained by development perfect whites in the high lights on dry ferrotype plates, and I think a good gaslight is better than murky daylight in this matter. Some two years since I showed you one of my positives; you thought it less white than many you had seen, but I forgot to explain that the building it showed was painted a stone colour, the picture was really lighter than the building. I gathered that you thought a good ferrotype dry plate would bring a good run of trade, and, encouraged with this, I have done all I could to get over difficulties in the matter. Two things I need (and all likewise following in the same line) are a suitable pyroxyline, and good light in which to expose the plates. With these I believe collodion dry plate positives will give us pictures that possess a charm all their own, and that are unfadeable under all ordinary conditions. With my plates I have obtained fully exposed pictures in one second of time, and with the same emulsion good negatives in three seconds.—I am, yours, &c.,

G. M.

London, January 11, 1892.

TONING BROMIDE PRINTS.

To the EDITOR.

SIR,—As the subject of warm tones with bromide prints has now come prominently forward, I think that some experiments that I made over two years ago may interest your readers.

I remembered, in the good old days of wet plates, that I had tried uranium intensification with such plates, and that, if good brown tones could be got with them, why not with bromide paper? I found such the case, but the colour did not satisfy me, and I tried the effect of several other chemicals on the uranium. These experiments I stuck on a card, and I found them by accident in my dark room, in the damp, two years after, most as fresh as when done.

When so many letters were written early last year on uranium toning, I treated several enlargements and got the same results. I found that a uranium bromide washed out in twelve hours' running water, but, if placed in a very weak solution of sulphate of copper (electro solution), it altered the colour to chocolate, or modifications, according to how much toned with uranium, and also as to how long left in the copper.

Chloride of zinc also has the same effect, but not so good.

I showed the experiments to the Eastman Company, and they at once asked if they were permanent; so I placed strips in a printing frame partly covered up, and left in the sun for a fortnight, but I found them fade. I am now away from my laboratory, or I have little doubt that I should have found something permanent.—I am, yours, &c.,

Nutfield, January 11. F. K. BARCLAY.

MINERALISED METHYLATED SPIRIT.

To the EDITOR.

SIR,—The above is the official name now adopted for the new methylated spirit. I have reason for thinking that the permanency of the alteration is by no means settled, and would urge agitation against it, as annoying and uncalled-for in the interests of "the greatest good of the greatest number." If the object is to make the spirit undrinkable, why not secure this by some addition which shall make it distinctly obnoxious *in effect* when taken internally, without at the same time punishing all users who apply it for legitimate purposes?

Referring to the letter of Mr. W. B. Bolton in your issue of December 14, the fallacy running through it will be so evident to practical men that it is hardly necessary to further notice it. I quite agree that the Excise order does not strictly define the origin of the mineral naphtha, but, whatever theories may be culled from text-books, I believe that in commerce the term is most commonly applied to coal tar, naphtha, and according to the order, the naphtha *must* have the property, added in the indicated proportion to methylated spirit, of making the mixture distinctly immiscible when added to an equal bulk of water; it *must* be milky. The lighter ones will not give this result, and are therefore not suitable. The specific gravity, ·800, shuts out, with other light oils, both benzine and benzoline. I think I have sustained my position, but am sorry that my brief note caused such evident irritation.—I am, yours, &c.,

Scarborough, January 11, 1892. JOHN WHITFIELD.

AN EFFICIENT HAND CAMERA.

To the EDITOR.

SIR,—In reply to Mr. Geo. W. Valentine's tardy acknowledgment of my letter of December 11, 1891, *re* How to Make an Efficient Hand Camera, which he says is an emanation of his own that, although the "Adelphi" was mentioned in several papers, both photographic and otherwise, he never saw or heard of it till he saw it described in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for this year, will Mr. Valentine permit me to say it is a singular coincidence that his description of an efficient hand camera, published only last month, should so nearly resemble the "Adelphi," patented in 1890, and shown in Liverpool, Southport, Birmingham, Manchester, and London.—I am, yours, &c., T. MILLER.

141, *Broughton-road, Salford.*

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column: but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Exchange, dry plates or photographic chemicals for a retouching desk with drawer.—Address, A. B., 107, Lake-road, Portsmouth.

Table piano, four octaves, steel vibrators, offered for half-plate modern camera, &c.—Address, W. HAGUENEAU, Dickleburgh, Norfolk.

Wanted, background, rolling press, or half or whole-plate camera, in exchange for a guitar.—Address, H. J. RIDDITCH, Smith-street, Warwick.

Will exchange a new six-inch burnisher for cabinet cold rolling press with plate, or will offer for sale.—Address, A. W., 31, York-road, Hove, Brighton.

Will exchange a ship's bulwark accessory, backgrounds, and half-plate portrait lens for a 10×8 portrait lens.—Address, W. H. COOKE, 2, Landport-terrace, Southsea.

About 200 lantern slides, of best quality, in exchange for camera, lens, or other useful photographic accessories.—Address, EDWARD HUTTER, 4, Colville-gardens, Bayswater, London, W.

Pair of fine backgrounds in flatted oils, interior and exterior, 8 feet by 88 inches, new and perfect, in exchange for good violin or banjo.—Address, W. HARE, Windsor Studio, Sutton, Surrey.

Pair of handsome backgrounds in flatted oils, on linen and roller, new, eight feet by eighty-eight inches, in exchange for good violin or banjo.—Address, WILLIAM HARE, Windsor Studio, Sutton, Surrey.

Wanted, fifteen-grain tubes chloride of gold for Watson's drop shutter to fit Ross' rapid symmetrical 5×4 lens, and Lancaster's quarter-plate eyelet clip.—Address, BERNARD GREEN, Derwent Mills, Cockermouth.

Will exchange a 5×4 camera, with six double backs, for a large-size "flap" shutter (time and instantaneous) and the Index to THE BRITISH JOURNAL OF PHOTOGRAPHY for 1889.—Address, C. W. CLARKE, 32, Market-place, Devizes.

Meagher's brass-bound mahogany *carte* camera, with repeating back and instantaneous shutter, two single backs (one new), and Grubb *carte* lens, for Dallmeyer's No. 1 wide-angle rectilinear.—Address, W. A., 13, High-street, Wexford, Ireland.

Three canvas backgrounds (one interior 12 ft. by 8 ft., one interior graduated 7 ft. by 7 ft. 6 in., one exterior graduated 7 ft. 6 in. by 7 ft. 6 in.) in exchange for half-plate rapid rectilinear lens.—Address, A. MIDY, 1, Dolphin-yard, Macclesfield-street, Shaftesbury-avenue, W.

Exchange large whole-plate portrait lens, three-inch diameter, by Derogy, Paris; Marion's ten-inch roll burnisher, nearly new; Kershaw's patent instantaneous roll shutter, diameter two and a quarter inches; also Perken, Son, & Rayment's instantaneous shutter, aperture two and a quarter inches. Wanted, studio chairs, rocks, balustrade, pedestal, table, or other useful accessories.—Address, PORTER, Photographic Studio, Chippenham.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & CO.," *2, York-street, Covent Garden, London.*

R. G.—Procure the tissue and sensitise it as you require it.

G. E. S.—We are happy to hear of your success with English plates.

W. A. MEIGH.—Of Mr. Henry Park, whose address you will find in the ALMANAC.

R. LEONHARDT.—If nothing else but water get to the hypo, its working powers will not be impaired.

C. J. WOOD.—"Nottingham limes" may be obtained through any of the dealers in lantern requisites.

G. MANSFIELD.—The fifteen-inch portable symmetrical lens will be the best for enlarging your 15×12 negatives to 18×23.

MR. G. KERSHAW writes to know the address of the sole dealers in stereoscopic views by the American Littleton Company.

SILVER.—The glass is oblong in shape, and should be optically plane. Directions for silvering will be found in the ALMANAC.

H. R. WILLETT.—Probably floating particles in the atmosphere. See our article on the subject a few weeks ago.

CHARLES BERNARD.—If you procure some good artist's canvas, the formulæ for emulsion-making and development in the ALMANAC will assist you further.

R. ROBINS.—The cause of the yellow stains described is that the negatives were not thoroughly fixed in the hyposulphite of soda. A longer immersion in future will avoid them.

SALOP.—The principal difficulty in your case has been the plates. Extra rapid plates are not at all suitable for lantern slides. Procure plates specially made for the work, and use the formula supplied with them.

COLLODION.—1. Rodinal is a one-solution developer in a concentrated form. For normal exposures one part of the solution to thirty of water is recommended. 2. Probably by over-exposure. 3. Three or four minutes. 4. Increase the quantity of pyro.

FRANK PIPER.—The patents extend over a period of fifteen or sixteen years, and we could not possibly devote the time to ascertain for you the particulars you require. These you may obtain for yourself at the Patent Office, Southampton Buildings, or by employing a patent agent.

W. V. MORRIS.—The ordinary lime jet, with a reflector behind, is what is usually employed. Coloured gelatine films may be obtained from most dealers in materials for fancy-box makers. Coloured glass is better than gelatine for projecting coloured light for scenic effects.

WARDEN.—It is pretty clear that your "fixed-focus" lens is not in proper focus for the work you have been attempting. If it has been adjusted for general outdoor work, such as street views and the like, it will not be in focus for indoor portraiture. Hence the cause of want of definition.

CYMO asks if there is any advantage in using a larger source of light, such as a large gas flame, and then subduing it, by several thicknesses of ruby glass, over a smaller light with, say, one thickness of orange and one of ruby?"—None whatever. It comes, practically, to the same thing in the end.

J. C. SHARLWOOD.—One of the best all-round lenses for taking groups out of doors is one of the "rapid" type. Or, perhaps, the next best—indeed it is preferred by some—a single lens of the old-fashioned landscape form, with its aperture somewhat enlarged. A single lens is admirable for open-air groups.

T. BRAMWELL writes: "I see you instruct 'W. M. L.' to make a small negative from a large one by making a transparency by contact printing. May I ask if he could not get as good results by making small transparency in the camera, and thus save the price of a dinner for his family (if he is so fortunate as to have one)?"

A. W. P.—1. As you are an entire novice at lantern work by all means begin with the blow-through jet, particularly as you are not going to use cylinders but bags. Ample light for an eight-foot screen will be obtained with such a jet. 2. There is no necessity, in your case, to put the coal gas under pressure in a bag. Take it direct from the nearest gas bracket.

S. BEVAN says: "I made some matt varnish according to the formula given on page 786 of the ALMANAC. I have added different proportions of benzol, but the varnish dries transparent. I have warmed the plate to various temperatures, but this seems to make no difference whatever. Is there no mistake in the formula?"—The formula is quite correct. Our correspondent's failure has been brought about by his warming the negative. The varnish must be applied cold.

X. O. W. (Carlisle).—In photographing flowers the background must be chosen to suit the particular flowers to be photographed. That which would be most suitable for one group might be just the reverse for another. In all cases the backgrounds must be selected, and arranged to suit the subject. Better study the flower studies of Mr. H. Steveus, Mr. and Mrs. Payne, and others. These works will give you more instruction than can be conveyed in this column. Our publishers will supply the back numbers referred to.

P. E. J. (Leeds) says: "On mixing some developer, pyro and sulphite of soda, it became a dark sherry colour in a few hours. Trying a week afterwards, I found it work just the same as if it were not discoloured. Do you see any objection to its use, as I do not wish to waste it unnecessarily?"—If the solution works all right, there can be no objection to its use.

R. O. W. asks: "1. If burnt-in photographs on porcelain and earthenware are patented or not?" Several patents have been taken out in connexion with ceramic photography, but, so far as we can recollect, none of them are in existence at the present time. 2. Any of the Staffordshire potters, who do fine ware, will supply plaques such as you require, but, we surmise, they will have to be made expressly to order. In this case a large number must be ordered at a time. 3. If the design be original, it can be registered, and will then become your property. A mere design is not the subject for a patent.

E. C. MAY writes: "Can you tell me how I can flatten out some Eastman films which have curled up so violently as to be almost useless in the printing frame? I unfortunately neglected the recommendation of the Company to keep them in a pressure frame, and immersion in water and in the glycerine soaking solution has no effect whatever. As some of these are very fine negatives, I should be sorry not to be able to print them, and I can't help thinking there must be some means of straightening them out and keeping them flat. I need not say I have already tried all the usual devices for flattening paper, &c., but this celluloid appears to be very much more elastic."—Possibly some of our readers can suggest a remedy to Miss May.

PAARL says: "I enclose enamelled scrap. Notice how the print, when pulled off glass plate, leaves part of enamel on glass. I can't think why. Can you suggest? Do you think it is grease? To remedy and doctor up my collodion I afterwards added a few drops of castor oil, as suggested by yourself in one of the year-books, but then the prints would not leave the plates at all, and stuck on like grim death, and I had to soak them again in hot water to get them off. 2. Like many other poor unfortunates, I am troubled with blisters in my prints, and I tried the suggestion of soaking them in spirits before toning, but I found then that they took an hour and more to tone, and many would have a mealy appearance when dried. I now use the spirits before fixing instead, and, although it uses up a deal of spirit, yet it's better than having them big blisters. Oh, those makers of albumenised papers, how I bless them! Three years ago we were never troubled with blisters to the extent as now."—In reply: 1. The cause of the trouble is want of adhesion between the collodion film and the gelatine used for enamelling. From the appearance of the piece of print we imagine too much of the gelatine is removed in the squeezing, or that the solvents of the collodion were not thoroughly eradicated before the print was laid down upon it. Without knowing definitely how our correspondent works, we cannot give any more definite opinion. 2. Try Mr. W. D. Richmond's remedy. Immerse the prints in methylated spirit as they are taken from the frames, and before proceeding to wash out the silver; then treat in the usual way. This is the most perfect remedy for blisters we have tried.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—January 28, Ordinary Meeting. Visitors invited.

CLEVELAND CAMERA CLUB.—The next meeting of the Club will be held on Tuesday, January 26. Subject for discussion, *Flashlight*.

PHOTOGRAPHIC CLUB.—Jannary 27, Annual Lantern and Musical Entertainment (ladies' night). February 3, *Photo-micrography*, Mr. T. Charters White.

PROPOSED PHOTOGRAPHIC CLUB FOR HEXHAM AND DISTRICT.—Mr. John Gibson, jun., of Battle-hill, Hexham, writes to the local paper, saying that it is proposed to form a photographic club for Hexham and district. A number of local photographers have expressed a wish for such a club.

PROFESSOR W. K. BURTON, in conjunction with Professor J. Milne, is preparing a work on the recent great earthquake in Japan, to be illustrated by a number of photographic reproductions. For the sake of comparison, there will be two plates showing, on a small scale, the effects of earthquakes in Italy and other countries.

MR. A. C. TOWNSEND, the cashier to the Birmingham Gas Department, was recently presented with a valuable set of bronzes by his colleagues as a mark of their esteem on the occasion of his leaving, after fourteen years' service. Allusion was made to the loss at the annual show of his admirable prints, and a hope expressed that in his new capacity as cashier and general manager to Mr. W. Tylar he would meet with every success and prosperity.

"THE Artistic and Literary Association, Limited," is the designation of a new publishing company, whose chief object is "to afford to those of its members who are artists or authors the unique advantage of sharing as publishers as well as originators in the profits accruing from their own works." Mr. Francis George Heath has consented to accept the position of managing director and editor in chief.

CONTENTS.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1656. Vol. XXXIX.—JANUARY 29, 1892.

SIMPLIFICATION OF URANIUM TONING.

Last week we directed attention to the use of a solution of potassium ferridcyanide and ammonium sulphocyanide as a reducer for negatives and bromide prints, the suggestion being made by Mr. Haddon in the course of some remarks on uranium toning, which will be found on page 60. As the subject of toning bromide prints appears, from the number of letters we receive, to maintain its interest among photographers, we will redeem the promise given last week to treat of the further suggestions of the gentleman named.

As ferrocyanide of uranium is soluble in alkaline solutions, and ordinary water, as is well known, on account of the presence of chlorides in it, usually has a tendency to give an alkaline reaction, the employment of an acid solution for washing the print will obviate any undesirable reduction of the toned image. But the value of this recommendation is increased when taken in conjunction with others in connexion with the subject.

The necessity for reducing the deposit of a uranium-toned print down to the desired depth and colour has, it seems, arisen from the improper composition of the toning solution. The brown deposit in the solution which appears so soon as the toning action commences is caused by the disproportion between the uranium nitrate and the potassium ferridcyanide. The former should be in excess, and thus the solution would remain clear, inasmuch as there would always be some uranium in solution with the undecomposed ferridcyanide, the ferrocyanide at the same time remaining in solution.

By the employment of a toning solution such as that suggested by Mr. Haddon—namely, a one per cent. solution of uranium nitrate in two ounces of water, to which a drachm of acetic acid and two grains of potassium ferridcyanide have been added, one gets a solution considerably weaker than that hitherto employed by the experimentalists, and one which fulfils all the conditions laid down for direct toning as opposed to the method of toning by reduction—that is, building up an image and reducing it with water. Not only is this a more economical way of working, but it is less troublesome, and is really a less roundabout method of toning.

Still another disadvantage of the old system of uranium toning that we may consider removed by employing a dilute solution of uranium with the ferridcyanide in excess is the need of developing the original picture to a particular tone. We have always held that there was never any real necessity for getting a brown-coloured image for toning with uranium, since we have in our possession slides of a normal black toned to a red colour by means of uranium.

A correspondent in the present number of the Journal draws attention to the fact that uranium solution can be used for toning platinum prints, which obviates the employment of the special paper for obtaining sepia effects. This further emphasises the fact that specially developed images of a brown colour are not necessary for uranium toning, since between the normal colour of developed bromide prints and platinotype pictures there is, as a rule, little, if any, difference. We may finally point out that the deposition of ferrocyanide of uranium on silver or platinum is a mechanical, and not a chemical, action; so that the process is, after all, not a toning one in the ordinary meaning of the term.

COATING GELATINO-CHLORIDE PAPER.

There are still, we have little doubt, many amateurs who sensitise their own albumenised paper in preference to using the ready-sensitised, while the practice is, of course, general in professional establishments. But, if those who go to the trouble of thus floating the paper on its sensitising bath were asked why they did not make their own gelatino-chloride paper, they would, in the majority of cases, be found to reply that they had not the time, or that the trouble and expense were too great.

Now, as a matter of fact, when a very slight variation has been made in the arrangements, the coating of gelatino-chloride paper is little, if any, more trouble than sensitising albumenised paper in the ordinary way. The emulsion, numerous formulæ for which have been published, presents no difficulty, nor does it require the care and nicety requisite in the case of bromide emulsion. It is not a washed emulsion, which robs it of nine-tenths of its terrors to most workers, and the ingredients may be put together in the light of an ordinary room; after a few minutes' digestion, to ensure the combination of the different ingredients, the preparation may be filtered, and is then ready to apply to the paper.

The trouble involved in preparing the emulsion is scarcely greater than that expended in getting the silver bath into condition for use, and, after that, there only remains the single operation of coating the paper and hanging it up to dry. The coating is no more trouble than floating, while the drying of the gelatine paper only differs from that of the albumenised after sensitising in that it takes longer; but this is of very little importance when a moderate quantity is prepared at once; and, as the paper keeps very well, this is the proper course to adopt.

As gelatino-chloride paper is growing in popularity, and undoubtedly possesses so many advantages, it will be surprising if it is not more generally introduced as an article of manufacture in many studios in the near future. Independent of the claim to greater permanency, it lends itself to such a variety of different styles of work, including matt or enamel effects, and may be applied to almost any character of surface with a little preparation in the way of sizing. Indeed, it is not

too much to say that gelatino-chloride emulsion forms a new power in the studio. Then, when the comparative cost is looked at, the user will probably be surprised how greatly it is in his favour as compared with albumen paper.

The first question that will trouble the amateur will perhaps be that of a suitable paper, though we believe that plain photographic papers are obtainable in small quantities at some of the dealers' establishments. In the event of such a paper not being directly obtainable, the best substitute must be found. For large work, or for matt or rough effects, this will not be at all difficult, as almost any of the various grades of cartridge or drawing paper will answer if the sizing be suitable, and, if not, this can be easily remedied; but for fine work, whether with the matt or enamel surface, the difficulty of finding a paper of sufficiently even texture, and without mill marks, will be much greater. We have known cases where "job lots" of inferior or damaged albumenised paper have been picked up at such prices as to make it worth while to remove the albumen and salting; but, of course, to fall back upon such paper at ordinary prices is out of the question.

Where, however, such a supply is available—and such lots are by no means rare at Stevens' and other sale-rooms—nothing better for our purpose could be obtained, whether for matt or surfaced effects. The first operation is, of course, to remove the salt from the paper, the albumen being removed or allowed to remain as may be thought best. If the albumen is to be removed, then all that is required is to soak the paper in several changes of cold or tepid water, until all traces of soluble chlorides have been removed. The sheets are then hung up to dry, and are better finished off with a hot laundry iron, to remove creases or unevenness. It is needless to say that the greatest cleanliness must be observed during the process, or the paper will suffer seriously in its damp state; it is also advisable to handle it as little as possible, and to avoid rubbing the surfaces together, which will raise the fibre.

When the albumen surface is to be retained, the method of preparation will be different. Naturally, the object will be to coagulate the albumen, and this can only be satisfactorily done by means of moist heat. It is of no avail to pass a hot iron, even at scorching temperature, over the paper, the albumen will remain as soluble as before; nor is it of any use to apply alcohol for the purpose, as has been often recommended. We have never found alcohol, even after prolonged application, to produce any effect in the desired direction. But a momentary dip into water at boiling, or nearly boiling, temperature performs the coagulation perfectly, and, after that, it only remains to allow the paper to soak in tepid water until the salt is removed. If it be required to operate upon full sheets, some little difficulty may be experienced with ordinary appliances, but sheets up to 12×10 can be satisfactorily manipulated with the appliances to be found in every household. It suffices to dip the paper momentarily into the hot water, and it is better to withdraw it at once, as the coagulation is instantaneous, while a longer immersion removes more of the size from the paper. So rapid is the coagulation, that, if a piece of paper be rolled up *dry*, and immersed in that state in boiling water until the latter has penetrated it, the albumen is coagulated without having time to adhere to the next surface of paper. This plan may possibly be of use for large sheets.

In the case of rougher kinds of paper, it will depend upon the normal sizing being suitable or not whether it has to be resized. When there is a great amount of alum in the size, the effect upon the colour of the image is sometimes so great as to completely ruin its capability of toning. In such instances the paper will require a preliminary sizing of arrow-root, applied by rubbing the smooth cold paste well into the pores of the paper with a piece of sponge. The sizing and even the texture of the paper exert a most powerful influence on the printing colour of the emulsion, the same emulsion perhaps giving on half a dozen different samples of paper as many different colours, and in many instances the difference will be clearly distinguishable after toning.

A satisfactory quality of paper having been obtained, the coating is perfectly plain sailing. We have a choice of two methods—first, pouring the emulsion on to the paper on a levelled slab; and, second, floating the paper on the emulsion. The first seems the more convenient in many ways, especially for small sheets, while for larger sheets it offers the promise of greater uniformity of result, as a measured quantity of emulsion can be applied to each sheet and allowed to level itself. In adopting this method it is desirable, if not absolutely necessary, that the paper be first damped in order that it may lie flat.

In working small sheets, say, up to $8\frac{1}{2} \times 6\frac{1}{2}$, though 12×10 may be manipulated in the same way with care, the wet paper is squeegeed on to a sheet of glass, and the surface dried with blotting-paper. A pool of emulsion is poured on to the centre, and this is led over the whole surface by means of a glass rod, or the finger, and the surface drained off pretty closely. The plate, with the paper still attached, is then laid on a levelled slab for a few minutes until the gelatine has set thoroughly, after which the coated paper is stripped off, and hung to dry. After a little practice, three or four dozen sheets of paper may be squeegeed, coated, stripped, and hung to dry within the hour. When manipulating large sheets, the same general course is followed, but the paper is squeegeed on to the slab and a measured quantity of emulsion spread over it; when set, this is stripped and hung in the ordinary way. The plan of coating large sheets has the advantage that the smaller sizes cut from them have clear edges.

The floating method is, perhaps, better for large sheets, and is, moreover, more expeditious, while it saves the necessity for damping the paper previous to coating. The floating may be performed in a variety of ways, but we shall confine ourselves to describing the method when a dish the full size of the sheet of paper is used. There are plans by which a sheet of paper is drawn over a narrow trough of emulsion which, in strictest parlance, can scarcely be called floating; but such methods generally involve the use of some special apparatus or appliances, and are therefore beyond the scope of the present article.

The dish to contain the emulsion must be provided with some means for keeping up the temperature of its contents; beyond this, any ordinary dish will answer. A common porcelain dish, standing inside a larger one, into which hot water is poured and changed from time to time, forms the simplest plan. The arrangement we employ ourselves consists of a tin dish with sloping sides, like an ordinary baking dish, fitting into another with straight sides, and about four inches deep, to hold hot water. The emulsion dish is coated with Aspinall's bath enamel, which we have found to answer this purpose and similar ones admirably.

To coat the paper, filter a sufficient quantity of emulsion into the upper dish, having filled the outer jacket with hot water. Arrange at one side of the dish an accurately levelled sheet of glass, a little larger than the paper to be coated, and let one

end of the glass project an inch or so over the edge of the dish. Lay a sheet of paper on the surface of the emulsion in the usual manner, and with the ordinary precautions to avoid air bells. Allow it to remain until it lies perfectly flat, when comes the only little bit of skill required. Some writers have directed that the sheet of paper be drawn backwards horizontally on to the levelling slab; but, irrespective of the fact that under such conditions it does not "draw" comfortably, we think a better result is obtained as follows.

Pick up the sheet by the two corners farthest from the levelling slab, and raise it quickly and without hesitation into a perpendicular position, with its lower edge resting against the edge of the levelling slab so that the drainings fall into the dish. By the method of lifting a considerable quantity of emulsion will adhere to the paper, but will rapidly find its way back into the dish. Watch this sharply, and as soon as the sheet has drained sufficiently draw it on to the slab and lay it down, commencing, of course, from the end where it is already in contact. The emulsion remaining upon the paper will quickly level itself, and in two or three minutes will be "set," and the sheet can be hung up to dry.

With regard to drying, an open room, in which a stove is burning, will supply all the heat necessary to dry the paper in a few hours. It is not well to dry too quickly, or the paper will "cockle," and give trouble when it goes into the printing frame. If dried at the ordinary temperature, beyond a slight curl there is no departure from flatness, and no trouble. When dry, the sheets should be put together under pressure, for the double purpose of securing flatness and protection from the atmosphere.

In conclusion, we can promise to any who may adopt the use of home-made gelatino-chloride paper a little surprise, not only with regard to the ease with which it is made, but also its economy.

TONING CARBON TRANSPARENCIES.

A few weeks back, in an article on *Lantern Slides by the Carbon Process*, we alluded to the facility with which the tones on these pictures could be modified after they were finished. That remark has brought us several letters, asking the method by which it is accomplished. In the first instance, it may be explained that the principle involved in the toning or intensification of a carbon picture differs widely from that of a silver one. In a silver picture it is the colouring matter forming the image that is acted upon by the toning or intensifying agent; whereas, in the carbon picture, it is the vehicle holding it—the gelatine—that is affected, and not the pigment, except in one or two cases. Here is one.

Supposing the tissue used is one that contains alizarine as one of the constituents of the colouring matter, as is the case with most of the purples and browns now in the market, and it be desired to give it a warmer tone, all we have to do is to immerse the picture in an alkaline solution, say one of carbonate of soda ten grains to the ounce of water, which will increase the redness or brilliancy of the alizarine. Again, in the case of permanganate of potash, which is so frequently used for the intensification of weak carbon transparencies and negatives. Here the permanganate tends to destroy such organic colouring matters as alizarine, cochineal, indigo, and similar materials, while manganic oxide is formed in the gelatine. Permanganate of potash is an agent seldom used for toning transparencies, by reason of the yellow tone it confers. If, however, the tissue be coloured with China ink only, as we believe is the case with the special transparency of the Autotype Company, and the application be brief, a pleasing brown tone may be obtained.

The most general plan adopted for toning carbon transparencies is analogous to dyeing; that is, the colour is formed by double decomposition in the film. By this method, as we have just said, it is the gelatine alone that is influenced. In making the slides, as described in the previous article, the glass supporting the picture is prepared with a substratum of insoluble gelatine. Now, it is manifest that any reagent which would act on the gelatine composing the picture would also act upon that forming the substratum, unless some precaution were taken to avoid it. As, however, the carbon tissue is coated with collodion prior to development, we have in the finished picture a film of that material intervening between it and the substratum. But the kind of collodion usually employed for the purpose is scarcely sufficient protection if the toning has to be long continued. Therefore, when it is intended to resort to toning, a somewhat thicker collodion, of a horny and repellent character, to which a small quantity of castor oil has been added, should be employed. Then the toning action can be completed before the film is permeated by the toning agents. Some years ago—see page 4 of our volume for 1885—Mr. E. W. Foxlee pointed out that by treating the transparency for a few minutes with very dilute hydrochloric acid, and then well washing it, the tendency to staining from the substratum was avoided.

It should be borne in mind that, as it is the gelatine alone that is acted upon, it is advantageous to select a tissue that contains a maximum proportion of it with a minimum of pigment. With such a tissue the image is obtained in high relief, whereas with that made specially for transparencies, which is highly charged with pigment, there is but a mere superficial layer of gelatine. Most of the ordinary portrait tissues fulfil these conditions.

With regard to the toning agents that can be employed, they are almost unlimited. For example, if a transparency be immersed in a dilute solution of perchloride of iron, then well rinsed under the tap, and afterwards treated with a solution of gallic acid, a rich purple black will be obtained. By substituting for the gallic acid pyrogallic acid, infusion of nut galls, logwood, &c., a great variety of purple and black tones can be secured, also by using other salts of iron for the perchloride. By treating the picture with proto-sulphate of iron, followed by ferrocyanide of potassium—the yellow prussiate—a blue colour, Prussian blue, will be obtained, suitable, if not overdone, for moonlight effects. A solution of bichromate of potash, succeeded by one of acetate of lead, produces a yellow—chrome yellow. Iodide of potassium first, and bichloride of mercury afterwards, gives a light red—iodide of mercury.

A very nice brown tone is obtained by first immersing the transparency in a one or two per cent. solution of nitrate of silver, then, after washing, applying the ordinary acid pyrogallic solution, to which a few drops of nitrate of silver solution have been added, as in intensifying a wet-collodion negative. With the silver method, it is advisable to just treat the picture with a dilute solution of cyanide of potassium, as a safeguard against after alteration.

Whatever method of toning or dyeing be used, it is necessary to rinse the picture well between the first and second treatment, otherwise there will be a danger of surface stains. The strength of the solutions used is of minor importance. The stronger they are, the quicker is the action and the less it is

under control. When they are very dilute, if the desired effect is not secured in the first applications, they may be repeated several times if necessary. But it should be kept in mind that an unduly long treatment may give time for the solutions to penetrate the collodion film, and thus cause staining in the substratum.

Photography Discovers a New Planet.—On some of the photographic plates taken by Dr. Max Wolf last month two minor planets were discovered. One has been identified as already recognised and numbered, but the other is believed to be new, and, if correctly so, will be numbered 323.

Meteorological Photographs Wanted.—On March 15 to 18 will be held an exhibition of instruments, charts, maps, and photographs relating to climatology. The Exhibition invite the co-operation of all who may be willing and able to help them, as they are anxious to obtain as large a collection as possible of such exhibits. Besides instruments and apparatus, they will be glad to show both photographs and drawings of suitable kinds.

Collection of Moon Pictures.—The Directors of three of the largest Observatories in the world, those of Lick, Harvard, and Paris—Professors Holden, Pickering, and Admiral Mouchez—are expected to co-operate in making a proposed volume, representing, upon a large scale, the best results that can be secured in the shape of lunar photographs, thus placing on record a detailed description of the lunar surface, the value of which, for comparison with observations and photographs of the future, can scarcely be over-estimated.

What has already been Done.—Professor Holden had a grant of two hundred dollars, made to assist in perfecting his apparatus for lunar photography. He offers to give the results of his work to the Smithsonian Institute for publication at some future day, if desirable. Then Professor Pickering has already obtained a valuable series of lunar photographs at the Harvard Observatory, which will be supplemented by others taken at the high-altitude station of the University, situated in the mountains of Peru. And, finally, Admiral Mouchez has promised his co-operation in securing photographs of the moon of the highest attainable excellence.

The Maddox Fund.—The following is a further list of subscriptions to this Fund:—George Mason, 2*l.* 2*s.*; John Spencer, 2*l.* 2*s.*; F. H. Verel & Co., 3*l.* 3*s.*; Albion Albumenising Company, 2*l.* 2*s.*; Annan & Son, 1*l.* 1*s.*; William Lang, jun., 1*l.* 1*s.*; Sir H. Trueman Wood, 1*l.* 1*s.*; R. W. T., 2*l.*; P. Lange, 2*l.*; A. W. Chapman, 3*l.*; T. C. Hepworth, 1*l.* 1*s.*; W. I. Chadwick, 1*l.* 1*s.*; London and Provincial Photographic Association, 2*l.* 14*s.* 6*d.*; L. E. Clifts, 1*l.* 1*s.*; C. G., 1*l.* 1*s.*; Spen Valley Photographic Society, 3*l.* 10*s.*; Professor Stebbing, 1*l.*; Thomas Curties, 1*l.*; *Photographic Review of Reviews*, 2*l.* 2*s.*; G. H. Rodwell, 2*l.* 2*s.*; Jeffs & Sons, 1*l.* 14*s.* We again remind intending subscribers that the Hon. Treasurer of the Fund is Mr. Francis Cobb, Riverdale, Twickenham, S.W.

Orthochromatic Plates for Astronomical Photography.—We are informed that MM. Fabre and Andoyer photographed the eclipsed moon at Toulouse Observatory on November 13, 1891; and some of the pictures obtained were exhibited by them at the meeting of the Paris Academy of January 11, with a note on the method of production. Collodio-bromide and collodio-chloride plates were employed, both kinds being treated with eosine and cyanine to render them orthochromatic. The former kind of plate was found to be relatively more sensitive to red and yellow rays than the latter, although both were stained with the same dyes. It is proposed, therefore, to use collodio-bromide orthochromatic plates to obtain photographs of Mars, Jupiter and the red spot, and coloured stars.

The New Methylated Spirit.—Messrs. A. & J. Warren, wholesale druggists and licensed makers of methylated spirit an finish, write: "As regards obtaining unmineralised methylated spirit, it is less roundabout to make *direct* application to the Commissioners of Inland Revenue, Somerset House, London. They, on receiving the application, will see that the proper officer deals with the matter. Your correspondent spoke of a £200 bond, but the Board of Inland Revenue do not, we are given to understand by Excise authorities, contemplate demanding this where less than fifty gallons is required per annum. Our experience hitherto is that no one connected with a medical or scientific institution has been refused the power of obtaining unmineralised methylated spirit, provided that the element of retailing does not come in, and that he be able to order not less than five gallons at a time of a methylator, *not a retailer*."

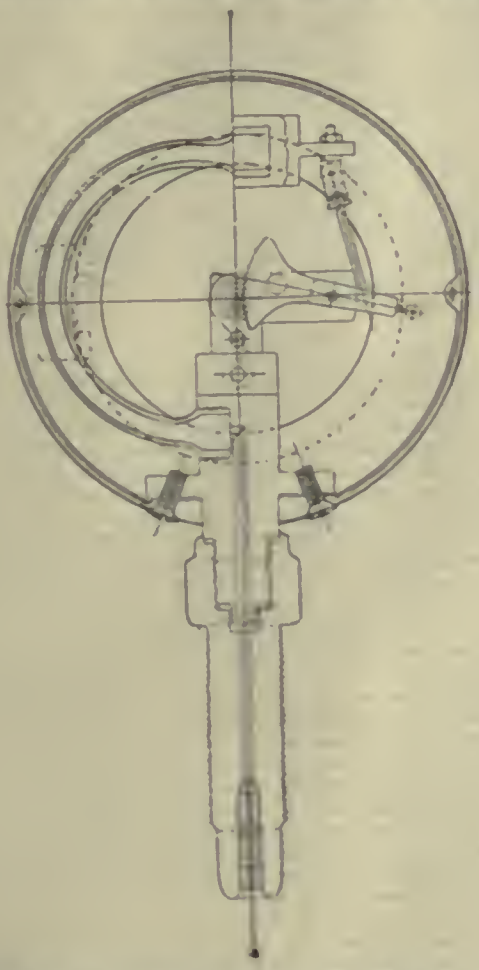
Ten Years' Sunshine.—Not—let us hasten to interpolate—continuous sunshine, is the leading part of the title of a useful new publication issued by the Meteorological Council, *Ten Years' Sunshine in the British Isles*, 1881–90. The observations have been taken at nearly half a hundred stations, and mainly by the Campbell-Stoke Sunshine-recorder, which registers bright sunshine only uninterrupted by mist or cirrus clouds. Jersey takes the happy position of the most favoured locality for almost every month of the year, the sun having shone there even in December for twenty-three hours out of every possible one hundred. Dublin comes next with a record of twenty-one per cent., while unfortunate London only registered two per cent. Everywhere December was the worst month. A great increase is noticeable in February, when Jersey again has the greatest amount, viz., thirty-one per cent., and London the least, nine per cent. In April, however, the Metropolis begins to improve more favourably with other places situated in the suburbs, and May is the sunniest month in the year, while June and July are by no means so sunny as might be expected. August is, generally speaking, a good month, September and October exhibit a considerable decrease, and November is the only month in which the Channel Islands are not the most sunny in the British Isles. The seacoast, generally, is more sunny than inland parts, while large manufacturing cities have a poor register compared with neighbouring localities outside their boundaries.

Bromine.—Bromine, which some years ago was "ringed" up to an extraordinary price, to be followed by an extremely depressed rate, has, for some time, been at what are more like normal quotations; to what extent the establishment of rival manufactories has influenced this, we are unable to say. From an interesting account in *La Nature* we learn, for example, that while no longer ago than 1887 America imported fifty tons per annum of bromine at a value of ninety thousand francs, that country now produces enough for her own wants and has ceased to import the chemical. Photography and medicine together are accountable for the use of more than two-thirds of the total amount produced, bromide of potassium being the form in which it is employed. The manufacture of colouring matter accounts for the rest. It is much employed as a disinfectant; after the terrible disaster of Johnstown it is stated that over three tons were employed for the purpose. In America, Michigan was the first seat of the manufacture, about seven years ago.

Incandescent Mantles.—The extreme fragility of the mantles employed in the new Welsbach system of incandescent lighting is generally recognised as a serious drawback to the use of the light, to overcome which Mr. E. Clifton has made a suggestion which, if carried out, would probably allow of the mantles being handled or moved with no fear of their being injured. This consists in forming an outer mantle or shell of pipeclay or similar material, in one side of which is left an aperture sufficiently large for the light to reach the condenser. A fracture of any portion of the textile mantle would be of no consequence so long as it was complete at that part through which the light was emitted to the optical system.

OXYGEN PRESSURE GAUGES.

A perusal of the valuable paper on *Oxygen Pressure Gauges*, by Mr. Budenberg, read before the Lantern Society on Monday evening, and which will be found on another page, will go far in restoring the confidence in pressure gauges that has not unnaturally been shaken by recent explosions. One could not listen to the practical remarks of this gentleman, see the specimens of the stages of manufacture, and note the tests employed, without experiencing a feeling of satisfaction that the days of explosions had passed away. We here show



a reduction of an enlarged drawing of the Schaeffer Budenberg gauge which was suspended in the room. The check patented by Mr. Morton Jackson for preventing the sudden rush of gas into the gauge is shown in the tube near the bottom of the drawing, and we join Mr. Budenberg in expressing our belief that *absolute immunity* from chemical explosions will be ensured by its presence. We invite a careful reading of the paper in question.

"IMPRESSIONISTIC PHOTOGRAPHY."

Perhaps there was never a greater contradiction of terms than that expressed by the two words heading this article, unless it be "impassioned photography," which the loose in speech have already affected. To listen to the crowd of scribblers, whom Mr. Whistler so often delights in castigating, the unsuspecting might think "impressionism" in art were a new thing, and yet 'tis as old as Aristotle, though the name serves as a label, nowadays, to distinguish the school of Pissaro and Monet, both scientific experimentalists rather than artists. But the height of ridicule was reached when a few *dilettanti* began to talk of *impressionism in photography;* and it is significant that these were the advocates of the most mechanical of all photography—*i.e.*, the *pinhole*—thus showing how the fool is ever discovering himself for the benefit of the multitude.

Impressionism has been looked upon as something mystical by the public, and yet it simply means that a picture is the individual expression of some painter. Velasquez was an impressionist, and so is Mr Whistler, but neither labelled himself anything but "artist," the assumption of the term "impressionist" being left for those who practise the art of the cheap-jack, and are convinced by the clouded "pinhole" on rough paper. Indeed, cafism could scarce go further than in the assertion that impressionism meant the subordination of detail to general sentiment, and so the driveller mistook breadth for impressionism. Is Velasquez' portrait of Philip IV. like a wretched pinhole printed on rough drawing paper?

The gist of the matter is that true impressionism is as old as the hills, and is merely a name for an *individual artistic expression without the help of mechanical aid.* The Parthenon was impressionistic architecture, the builder's villa is not; the Venus of Milo was impressionistic sculpture, the work of the modern Italian is not; the paintings of Velasquez are impressionistic, for he ignored the *laws* of perspective, as have all good artists; the work of Mr. Frith is not. An impressionistic photograph is a mere contradiction of terms; *no such thing can ever exist*, for the photograph is a *mechanical* drawing of something *objective* in nature, no matter how it be focussed, or by what method taken; it is not an "impression" at all, it has passed through no *mind*, "as through the last alembic," but is an impersonal, machine-made drawing. Therefore, to talk of impressionistic photography is to court ridicule and write oneself an ass.

As I have previously said, those who in photography have dared to assume this title are the most mechanical of all photographers—more mechanical than the "sharpist;" for the "pinheadist" focusses by measure or not at all, and has no power of seeing how his focus comes, and modifying it by stops; moreover, the drawing is not nearly so like an ocular impression of objects as is the drawing obtained by focussing the chief object and throwing the rest out of focus, though all methods give petty and unsatisfactory results.

That painters long ago felt the artistic pettiness of the ordinary perspective drawing is well known, and any one with a knowledge of perspective can apply its laws to pictures of the great masters of painting, when they will find those pictures are not built up in accordance with the laws of perspective at all, but solely upon individual impressions. On the other hand, such a study will reveal to the student why all pictures produced by the help of mechanical aids look so petty, to wit, Canaletto and some of the Dutchmen, though Canaletto's magnificent colour to some extent hides these defects. I believe Fortune has the credit of being the first to publicly disown the use of perspective; but that matters little, for our eyes tell us others discarded it decades before, and, if Fortune made such claim, the worse for him, for it stamps him as vain and dishonest—qualities seldom found apart. Quite recently a London impressionistic painter told an interviewer that Impressionism had nothing to do with photography. How the painter must have despised his pupil when he found it necessary to tell him that very obvious fact! It is useless for *dilettanti* to wriggle and call things by false names; photography is not art, and even to use photography as a basis for art, as did Mr. Mortimer Menpes, is but to get yourself looked upon as a charlatan and impostor. *Vide* also also the correspondence upon Mr. Herkomer's famous *Idyll*. If any student will select a suitable landscape, and watch it under the changing conditions of atmosphere, light and shade, for a few months—making notes on every new effect and taking photographs of the different effects—then comparing them with his notes—he will, at the end of six months, feel like kicking his lying camera to the zenith, and go stone-breaking as a more honourable employment. There are a few photographers with artistic tastes, and let me advise them to begin at once and learn to draw, and take up etching or water-colour painting, and let them tell us what they think of "art" (?) photography; and, as for the great body of amateurs, they would be far better occupied playing golf—both for the sake of their health and manhood; for there is some quality in amateur photography that seems to eat into the honour of many of its practitioners, and lead them into misrepresentation and worse sins. That quality is *vanity*—for your amateur photographer is the vainest creature on this globe—the first row of the ballet excepted. Already the velvet coat—that badge of the artistic pretender—is to be seen in the halls of *the art*.

A. R. S.

ART AND GENERAL NOTES.

"Picture Frames."—We understand that in the Corporation Art Gallery may now be seen the portrait of the German Emperor which his Imperial Majesty presented to ex-Lord Mayor Savory. *The frame is said to be elaborate.* The portrait of Alderman Savory, in his Lord Mayor's robes, is also exhibited at the Guildhall Gallery. No artistic interest can be attached to these pictures, and the same

remark does not distantly apply to some of the exhibits of the late Photographic Exhibition, the frames of which elicited universal condemnation.

Photogravure.—It is allowed that the increasing popularity of the art of photogravure is becoming very marked. Many of Sir Frederick Leighton's pictures are reproduced in this manner. What is for the public good, however, says a contemporary, is sometimes attended with disadvantages. There can be little doubt that the art of photography practically destroyed miniature painting, and it would be something to regret if photogravure was to be the means of stamping out mezzotint and line engraving.

Medals in Calcutta.—The Calcutta Art Society has awarded the Viceroy's gold medal to Mr. W. H. Jobbins for his *View of Kinchinjunga*, whilst the Society's gold medal has gone to Mr. W. H. Vernon for his painting of *A Lonely Mere*. Mr. Jobbins is a member of the Photographic Society of India, and we should be pleased to know that the picture which gained the Vice-Regal award in question was a photograph.

Artists and Photography.—Mr. C. P. Sainton is about to place on exhibition at Messrs. Dowdeswell's galleries a series of illustrations of *London Street Life*. We believe that Mr. Sainton is one of the new school of artists that does not disdain the direct employment of photography, although the school in question displays some reluctance in having the fact made known in art circles. Why is this?

GAUGES FOR HIGH-PRESSURE GASES.

[A Communication to the Lantern Society.]

The frequent recurrence of late of more or less violent explosions connected with the use of pressure gauges on oxygen cylinders appears to have created much uneasiness, and even alarm, in the minds of all interested in the application of these cylinders for lantern work. In consequence, pressure gauges in general have been emphatically condemned; and even upon the best authorities, lanternists are strongly advised to discontinue their use entirely. The great utility of these gauges in enabling the manipulator to readily ascertain the exact quantity of gas contained in a cylinder is, however, universally acknowledged; and, before urging the discontinuance of their use, careful inquiries should surely be made to ascertain what has been the precise cause of these accidents, and whether means cannot be found or devised for preventing them in the future. In claiming this amount of consideration on behalf of these instruments, I would plead that, so far as my experience goes, these accidents invariably admit of a simple explanation, and are the result of either gross carelessness or ignorance on the part of the maker, or operater.

All that is required is that lanternists should assure themselves that the gauges they use are properly made and fitted for the particular purpose upon the principles which are now fortunately well understood; and, if this were universally done, I have little hesitation in prophesying that nothing more will be heard of these explosions—at any rate in connexion with pressure gauges. It is the special object of this paper to draw your attention to the necessary safeguards; but, before entering upon a consideration of these explosions themselves, it will be necessary to give you a cursory description of the construction and mode of manufacture of pressure gauges as practised by my firm.

The Parts of a Gauge.

A pressure gauge as used for this purpose consists essentially of a steel tube of elliptical section bent to the form of a semicircle, one end being screwed to a boss through which the gas under pressure is admitted to the tube, whilst the other end is free to move, being simply closed by means of a brass cap screwed on to the tube. When pressure is admitted to such a tube, the section has a tendency to change from the elliptical to the circular form, and, in consequence of this action, the curvature of the tube is reduced. The tube, in other words, shows a tendency to straighten, causing the free end of the tube to move away from the boss, and the degree of this movement indicates the amount of pressure which has been brought to bear on the tube. The movement is magnified by the aid of a toothed quadrant which is in gear with a pinion carrying a pointer, and the latter indicates the pressure on a graduated scale, the whole being mounted in the manner shown in the illustration. In order to ensure accuracy of indication, it is of primary importance that all the parts of a gauge be fitted up in the nicest possible manner, so as to obtain perfect freedom of movement in the various joints and bearings without the slightest play in the direction of movement. Any such play or back-lash would be magnified by the multiplying gear, and render considerable variations on the scale of the dial. A slight back-lash between the teeth of the quadrant and pinion is, of course, unavoidable, and in all well-made gauges this is taken up by means of a fine spiral hair spring.

The most important part of the gauge is the tube, and the reliability of a gauge depends chiefly upon the choice of the material for the tube, and the care bestowed upon its manufacture and testing. For indicating ordinary boiler pressures of, say, about one hundred pounds per square inch, tubes made of a copper alloy are ordinarily employed; but, for the high pressures which have now become customary in the storage of these gases, gauges with steel tubes are nearly always used. Some gauges are fitted with ordinary drawn steel tubes, but these are vastly inferior to tubes turned out of solid steel which has been specially selected and is suitable for this purpose. The tubes in all gauges manufactured by my firm are bored and turned out of a special brand of Sheffield octagonal or pressed steel, the tubes being made in a very large variety of shapes and strength according to the amount of pressure they are required to register, and the conditions under which they are intended to be worked.

Testing the Tubes.

For the particular purpose with which we are now more immediately concerned, tubes are used which will safely stand a pressure of 360 atmospheres without taking the slightest "set," the diameter of the tubes before being flattened being about one half of an inch, with a wall thickness of nearly one-sixteenth of an inch. After the tubes have been turned, they are polished inside and out, to remove every trace of tool marks, and they are then microscopically examined by light reflected from a mirror, any tube showing marks or scratches being rejected as unfit for use. The tubes are then carefully flattened and bent at a moderate heat, and to perform these operations with entire satisfaction necessitates the greatest experience and skill. Finally, the tubes are hardened and tempered, and a great deal also depends upon the manner in which these operations are performed. The tubes are then again carefully examined, and, if proved satisfactory, they are subjected to a series of tests. For this purpose each tube is temporarily attached to a special testing apparatus, the free end being connected with a mechanism which is identical in all its main features with the works of the gauge which the tube is intended to fit. The tube is then submitted to a pressure of 360 atmospheres for one hour, or longer if possible, and careful note is taken, when the pressure is released, whether the pointer of the facsimile gauge returns to zero. If not, the tube is rejected and destroyed, a strict rule being made never to temper a tube twice, in case the first attempt should not have proved a failure. The bursting strength of a tube successfully completed in this manner will be between seven and eight tons per square inch, or exceeding 1000 atmospheres; but these are by no means the strongest tubes that can be manufactured, and we have produced gauges which indicate regularly and successfully pressures up to thirty tons per square inch, or 4500 atmospheres, being nearly forty times the highest pressure employed in oxygen cylinders. The tube is next attached to the carrier boss, and the cap is screwed on to the free end of the tube, the metallic joint at both ends of the tube being made by means of a sharp-edge projection, which is turned on each end of the tube, and beds itself into the material of the boss and cap. The multiplying mechanism is next fitted up, the several parts being made beforehand in large quantities and by special machinery. The gauge is then secured in its case, whereupon it is again attached to a test pump. The multiplying mechanism is now adjusted, so as to give the required range of movement to the pointer, and, the dial having been temporarily inserted, the scale is marked out point for point by comparison with two large standard test gauges, which are periodically tested upon a dead-weight frictionless testing machine specially constructed for this purpose. Each dial is written by hand, and is subsequently inserted into its gauge and secured by means of three screws. The pointer is then fastened to the pinion spindle, the gauge is completed, and submitted to another final test upon the hydraulic test pump. A gauge made in this manner, will, if fairly used, permanently indicate on the dial any pressure with extreme accuracy, and may be kept under constant pressure without liability to deterioration.

Tests for Defective Gauges.

There are, however, a large number of gauges in use which do not comply with these essential requirements, some specimens placed upon the market being, indeed, very inferior in construction and workmanship; and, as there is little to distinguish these gauges in external

appearance from efficient instruments, it may be useful to indicate a few simple tests by which the grossest faults, at any rate, can be discovered by any one. For this purpose it is only necessary to remove the brass rim and glass, and to fix the gauge upon a gas cylinder charged to the full pressure of 120 atmospheres. Before opening the valve, lift the pointer over the pin against which it rests, when there is no pressure on the gauge. By means of a pencil, mark upon the dial the exact spot where the pointer settles; then lift the pointer back and open the valve. After leaving the gauge under pressure for, say, a quarter of an hour, or, better still, half an hour, close the valve, release the pressure, and, after again lifting the pointer over the rest pin, observe whether the pointer comes back to the exact position which it occupied before. If there is a perceptible variation the tube has given way, and this forms conclusive evidence that the gauge cannot be relied upon. A more rigorous test consists in making the same experiment under the maximum pressure to which the gauge is marked, say, to 250 atmospheres, or even to a pressure exceeding this, and any well-made gauge will easily stand the test.

The above tests, which any lanternist may perform, will suffice to bring to light the worst defects. When the gauge is under pressure the pointer should be gently moved both ways, and it should be observed whether it invariably returns to precisely the same indication. Any variation would be the result of back-lash or sticking, and points to inferior workmanship.

Some Dangers.

Having, then, become acquainted with the construction and working of these gauges, we will next consider the dangers connected with the use of these instruments for high-pressure oxygen and hydrogen, or coal-gas cylinders, and at the outset we must distinguish clearly between explosions, which are the result of bursting of the tube, and chemical explosions, which are due to the firing of inflammable matter in the tube or connexions of the gauge. By far the largest number of accidents which have hitherto occurred are the result of *chemical* action; but some of them must undoubtedly be attributed to a simple bursting of the tube, due either to bad construction or to a defect in the material of the tube. In some cases the tubes have been turned out round, or have been insufficiently flattened, and, in order to obtain sufficient sensitiveness, makers have reduced the thickness of the tube to such an extent, that it has sooner or later burst from sheer weakness. In such instances, the sudden rush of gas under the enormous pressure into the *gauge* body instantly puts the case under a pressure which it is not calculated to stand, and a violent explosion is the result, in which the *case* is generally shattered whilst the interior of the gauge may be left fairly intact. An accident of this nature is not likely to occur with a well-made gauge; but, as even the best tubes may in the course of years develop defects which could by no possibility have been discovered in manufacture, it is, nevertheless, advisable to provide every gauge with a protection against accidents of this nature. For this purpose the best safeguard consists in fitting the gauge case with openings, or other free vent, combined with a check in the inlet to the gauge. The latter will prevent the sudden admission of pressure to the gauge, and any pressure which might otherwise slowly accumulate in the gauge case will be relieved by the vents in the case.

In all gauges manufactured by my firm during the last year, or thereabouts, the vent has taken the form of a loose hinged back or valve, which is held closed by means of a light spring. If even a very light pressure is admitted to the case, this valve will be forced open, and the pressure is then instantly relieved. The entire efficiency of this safeguard has been experimentally demonstrated.

The investigation of the second and more important class of accidents which are attributable to chemical explosion is not quite so simple, but the general causes are well understood. They are produced by the ignition of oil or other inflammable matter in the tube, the heat necessary to effect the ignition being the result of the sudden compression of the air or other gas in the gauge tube and connexions. When the valve of a cylinder charged to 120 atmospheres is suddenly opened, the whole of the contents of the connexions to the regulator and gauge are instantly compressed to the 120th part of their former volume into the most distant parts of the internal passages, such as the extreme end of the gauge tube; setting aside the effect which the mixing of the gases will have, the action is similar to what would occur if the contents were compressed by a piston. In this way, sufficient heat is set free to raise the temperature of the compressed body of air or other contents to a considerable degree of temperature; and this will suffice to ignite any highly inflammable matter that may have lodged in the extreme end of the tube or connexion.

This may be easily and safely demonstrated by a simple experiment. A straight tube, say, six or seven inches in length—one end of which is closed by means of a cap, into which a piece of tinder or other similarly inflammable matter is secured—is attached to a cylinder containing air compressed to, say, 120 atmospheres. By suddenly opening the valve, sufficient heat will be set free to ignite the tinder. I have even successfully performed this experiment with a tube only four and a half inches long, and with a pressure of barely eighty atmospheres. Mr. Whitefield (Vice-President of the Manchester Photographic Society) has kindly conducted an experiment for me, with the object of determining the temperature of ignition of the tinder used in this experiment; and he finds that this is about 410° Fahr., which, I think, is about the same as the firing temperature of an explosive mixture of hydrogen and oxygen. If such ignition can be produced in the presence of air only, how much more likely may this not be in an atmosphere of oxygen! Let us now suppose that traces of oil have been left in the gauge by the maker, or that oil which has been used for lubricating the valve of the cylinder, or other purpose has been blown into the gauge tube during an admission of gas. If such a gauge is applied to an oxygen cylinder immediately after use on a hydrogen cylinder, and the valve is opened suddenly, the heat set free will be sufficient to fire the mixture of oxygen and hydrogen in the end of the tube, and this, in turn, will ignite the oil in the tube, with the result that a violent explosion will occur, owing to the rapidity and intensity with which the oil is consumed in the presence of oxygen; but, even without having hydrogen present, the heat evolved by a sudden opening of the valve may be sufficient to ignite directly any oil that has gained access to the tube. Possibly some of the oil might be carried forward by the in-rushing gas in the form of spray; and, in an atmosphere of oxygen, this would probably ignite at a comparatively low temperature. The temperature of any oil in the tube may even be materially increased by friction resulting from the in-rushing gas; or the particles of oil, carried forward with great violence, might become heated by friction against the sides of the tube and by the sudden impact with the end of the passage; and all these circumstances would increase the danger of explosion.

Oil not Used—The "Jackson" Check.

Since the danger of the presence of oil in these gauge tubes has come to be realised, we have discontinued the practice of using oil for dividing and testing these gauges, pumps filled with water having been adopted instead; and the greatest care is exercised to prevent any oil from coming into contact with the gauge fittings during manufacture. Special water pumps are now set aside purposely for this work, and the connexions are so arranged that it is impossible for any workman to screw the gauges on to an oil pump without providing himself with a special connexion for this purpose—all chances of a mistake being thus overcome. The pumps themselves are fed from the town's main, and, after each test, the contents of the pumps are discharged into a white enamelled trough, in which any traces of oil can easily be detected. Subsequently, the contents of the tube are extracted by means of a vacuum pump, and are examined for oil. Finally, the remnants are blown out by admitting air pressure to the gauge at 100 or 120 atmospheres, and suddenly releasing this pressure. In this manner, everything that human foresight can provide is done to minimise the chances of the tube containing, when completed, even the slightest traces of oil. But, in spite of every care, the entire absence of oil or other inflammable matter cannot be absolutely assured; and, even if this were done, there always remains the danger of oil gaining access to the tube accidentally when a gauge is in use. Therefore, whilst continuing to exercise every care to keep away all traces of oil, the ultimate safeguard against accidents of this description must be looked for in another direction, namely, by checking the sudden in-rush of gas to the gauge when opening the valve, so that the pressure in the gauge rises gradually, and the heat evolved has time to be absorbed by the material of the gauge tube. This may be accomplished by opening the valve very gently; but, as this gentleness cannot always be ensured, owing to the frequent stiffness of the valves, carelessness, and want of skill, it is indispensable, in order to secure perfect safety, to fit each gauge with some means for automatically checking the admission; and, whatever check is employed for this purpose, it must not require any particular attention or manipulation. Various devices have been brought out for this purpose; but, of all that have come within the limit of my experience, the check patented by Mr. W. M. Jackson, of the Manchester Oxygen Company, is by far the simplest and best. This consists in screwing a plug, through the centre of which a fine hole has been drilled, into the foot of the connecting shank of the gauge. Upon this plug are placed a number of alternate layers of copper wire gauze and felt cloth, in the manner shown in the illustration. Another screwed plug, similarly drilled with a fine hole, is then added, and the alternate layers of gauze and felt are compressed between the plugs. This packing retards the pressure of the gas, even when suddenly turned on; but it does not prevent the ultimate admission of full pressure to the gauge.

Conditions of Absolute Safety.

I am of opinion that absolute immunity from danger of chemical explosions in gauges can be ensured by the proper use of this check, and it is not too much to say that no gauge used for this purpose should be without it or some equivalent device which has proved satisfactory. If a pressure gauge is of sound construction and well made, and fitted with the adjuncts which I have described, and these are kept in proper working order, it may, I think, be accepted that such an instrument is absolutely safe, and there need be no fear of any accident from known causes. The experiment which I have performed before you suggests, however, that even without the use of a pressure gauge an explosion in the connexions is possible, provided the end of the passages in the connexion is sealed and the pressure suddenly admitted. Generally speaking, the regulator valve is full open when the cylinder valve is being opened, and there is, then, little danger of heating in the regulator connexion; but circumstances might arise in which pressure is suddenly admitted with the regulator valve closed, and here the conditions are precisely similar to those which exist in the cases of gauge chemical explosions. This might, for instance, occur if the valve is opened twice in succession, the first opening having been sufficient to set the regulator to work.

If the pressure is then released and readmitted suddenly, an ignition might occur in the regulator connexion. It appears to me that the same thing might happen in using a cylinder valve which is not quite true, and which is worn to an oval shape in the seating. If such a valve is opened, a puff of oxygen sufficient to fill the regulator might be passed, followed by a temporary closing, whereupon a sudden opening might produce in the regulator connexion the precise conditions for an explosion. These considerations suggest the theory that some of the explosions which have been attributed to pressure gauges have probably originated in the connexion of the regulator itself. The danger under consideration can be minimised by making the connexion to the regulator as short as possible; and, generally speaking, long passages of any kind between the cylinder valve and the regulator or gauge should be rigorously avoided, as constituting a decided source of danger; and, wherever it is necessary to have a long passage, the end of which is or may become sealed, a check should be provided.

If lanternists would only devote their attention to these points, and assure themselves that the principles here laid down are carefully carried out, we shall have no more explosions; and my labour in preparing this paper will have been amply awarded if it should have the effect of arousing the members of this Society, and through their medium other lanternists to the importance, of carefully studying this subject.

C. F. Budenberg.

ON THINGS IN GENERAL.

If the editor does not think it will be reopening the closed discussion on Perspective, I should like to say that I, too, passed the South Kensington examination in Linear Perspective (among others) a score of years ago, and that I then obtained a certificate qualifying me to teach that and other subjects.

Those who were not at the meeting of the London and Provincial Photographic Association on the last day of the old year should read the published account of it. There will be found a real kernel of valuable information upon matters connected with the fading of photographs—information which is not all available in such a concise form in any work hitherto published. Something was said about the fading of bromide prints. I confess to being no lover of such prints, but I would have fair play dealt out. Now we all know "one swallow does not make a summer," neither does one faded print damn a process. As good a story as can possibly be told about this question is rapidly being put together. Whether out of his supreme wisdom with such an object in view, or by a matter of chance, it will be observed that Mr. Traill Taylor, in his editorial capacity, has for some years past chosen the bromide process as the medium for producing the illustrations to The British Journal Photographic Almanac. Before many years are over there will be hundreds of thousands of witnesses as to the possibilities of bromides in the direction of fading or non-fading. Let every one carefully preserve his Almanacs for this purpose alone is the advice of

Free Lance.

THE PRICE OF SILVER.

On Wednesday last bar silver declined to 41⅛*d.* per ounce, the lowest price touched since the year 1888.

PRESSURE GAUGES.*

A word upon the oil question and testing. In the process of making steel tubes, when duly shaped they are heated and carefully tempered in oil, after the fashion of tempering the famous old Toledo sword blades, which were not perfect unless they became straight after the point had touched the hilt. The oil is burnt off in the process. After that, when the time for testing arrives, the tube is attached to a dial plate and filled with water, every dial plate being graduated for its own tube under actual known pressure; but neither water nor oil should be allowed to remain in a tube, and the method of clearing I saw was to fill the tube before inserting the safety check with high-pressure gas. This was allowed to escape suddenly, when it carried out most unmistakably whatever traces of moisture there were in it. This was repeated to ensure perfect dryness. No oil is used in testing, but water only, which is fed into the pump in Messrs. Schaeffer & Budenberg's testing room from a vertical glass receiver placed in a good light on a level with the eyes of the workman, so that any impurity can be seen at once before passing into the pump, and when I chanced to call the water was clear and bright.

I was informed that at their factory in Germany, where the steel tubes are made, the water used is taken direct from the town supply, and, after passing out of the steel tube, is ejected into a white enamelled receiver for careful examination to discover the slightest trace of oily matter. This indicates the scrupulous care taken in this detail of manufacture. But

> "The best laid schemes of mice and men
> Gang aft a-gley."

And suppose that notwithstanding check valve and care of all kinds, a flaw develops in the steel, finest of its kind though it be, and the tube does burst—what then?

If a tube should so burst, the surrounding case is strong enough to prevent it flying out, the case itself only bursts when filled with the high-pressure gas; to anticipate and prevent any such evil, which, by the way, has not yet occurred with a turned steel tube and check valve, a shutter has been placed at the back of the gauge, closed by a light spring, but which opens readily with a little internal pressure, and thereby would allow any gas to escape harmlessly and prevent its breaking the glass.

In such a gauge all evil seems to be completely forestalled and guarded against, but doubtless, if any one will suggest any other source of inconvenience, I need not say danger, some remedy or safeguard can be provided.

I should like now to give you a hint as to testing your own gauges for efficiency. The entire principle of gauges of this type depends on the elasticity of the metal employed in the tube; if too soft or badly tempered, or of unsuitable quality, it will become set and not return to its original shape after being subjected to a high pressure, and frequent repeated strain will increase the discrepancy shown on the dial; therefore the needle should always return to zero promptly when the gauge is emptied, and when it is repeatedly applied to a full bottle at the same pressure, at each trial it should register exactly the same. Well, all gauges ought to do that, but unfortunately they do not; therefore look to it as an indication of a fault somewhere. The needle should be lifted over the zero pin and a mark made on the dial at the point where it rests stationary, then put it back over the pin and apply your pressure test; don't be in a hurry with the test, let the tube remain fitted at the highest pressure for, say, a quarter of an hour, then take off the pressure, gently lift the needle once more over the zero pin, and observe if it returns to the mark; if not, there is a "set" in the tube. If you are a malicious person—I am not looking at any one—no doubt you will sell that gauge to your enemy.

There is another fault met with in a gauge made by a bad workman, or in one of the "too-cheap" sort, that is the back lash caused by loose-fitting pivots and bad rackwork. I had a gauge in my hand a little while ago in which the pitch of the rack and of the pinion were different, yet the exterior of the gauge would not be objected to by most purchasers. A moderate amount of back lash allows of an error on the dial of five to ten atmospheres, important to those who are using up all the contents of a cylinder and want to know how long it will last. To check this fault, pull the needle over first on one side a little and then to the other side a little, and see if in both instances it returns *exactly* to the starting point; if not, it is faulty in action, and also indicates low-class workmanship.

A lanternist is much better without a gauge than with one that does not register correctly, or is made of bad material or with bad workmanship.

There are other forms of gauges made or in use; one that depends on the direct action of an issuing current of gas on a spiral spring

* Concluded from page 58.

arranged something like a common spring letter-balance. Another acts on a piston in a tube, the piston being forced back against a spring with an index attached to it. These seem to me to be liable to irregularity in action, and, from their diminutive size, not capable of reasonable correctness.

I should not like to stand before one in use, lest a shot from the piston reminded me of the traditional little volunteer who went home without his ramrod after an evening's practice at the butts. The thing may be all right and strong, but to me it looks rather fragile. I have had no experience with it.

I have had bottles said to contain the same quantities; the gauge showed they contained the same number of atmospheres, but their external dimensions were very different. How can the right quantity be ascertained? If you have hired a bottle, you can only rely on the maker's good faith until you have emptied it; it is then a case of "locking the stable door after the horse is stolen." But you may prove your case, and for any cylinder you purchase you should do so, by weighing it when full at 120 atmos. (or any other known pressure), and again when empty. In the case of oxygen, the net weight will show the number of cubic feet, if the ounces are divided by 1·43, as one cubic foot of oxygen weighs 1·43 ounce. Coal gas is much lighter—say half ounce per foot—and needs more careful weighing; but, as it is only on special occasions, for proof purposes, such trouble would be taken to weigh accurately, and few persons have access to scales that will balance twenty or thirty pounds accurately, a gauge is practically a necessity for a lanternist, whatever may be said by some people whose nervousness has over-balanced their common sense for a time.

When your cylinders and gauges are checked, and proved to be of sound, high-class workmanship, they may be relied upon without fear as good servants; but oil and carelessness should be avoided in their use, lest they become bad masters. H. M. Whitefield.

ISOCHROMATIC PHOTOGRAPHY.

[A Paper read before the Holborn Camera Club.]

In discussing the comparative merits of photography and drawing as delineators of nature, an unthinking mind would doubtless award the palm of accuracy to photography. Those who know most of photography will, with regret, be the most ready to acknowledge the untruth of such a decision. Our tools limit our capacity to an extraordinary degree, and it does not take a student of photography long to discover wherein lie its defects. Lenses too often give untruthful form, whilst plates translate colour erroneously. Both faults are capable of some degree of correction, and some few practical ideas on the question of colour correctness may advantageously be considered to-night.

Isochromatic photography has had many champions and many opponents, but few are brave enough to say to-day that it is not one of the most important strides that photography has made recently. It may, of course, be readily admitted that we have not as yet reached anything like perfection, but it is the initial step in the right direction, and, like the child who begins to walk, having once started off, may hope to rapidly acquire power to take further strides, until our progress is fully developed.

The eye looking at these coloured papers sees, apart from the colour itself, certain intensities of light reflections, and judges that the blue is the darkest, the yellow the lightest, photograph these with an ordinary plate, and we have these intensities reversed. The sensitive film is more impressed by the blue rays and less by the yellow, and a print from a negative of such a colour scheme gives yellow as almost black, and blue as almost white, with gradations of difference in the intermediate colours.

Probably every owner of a camera has experienced the almost inevitable disappointment which marks his earliest efforts in landscape work. He sees on his ground glass a picture full of all that goes to make a picture, and this transcript lacks too often all those qualities. It is not that this photograph lacks colour (that he would expect), but it is the fact that it lacks true translation of colour into monochrome, that robs the view of its value. We may say that correct exposure and correct development alone give true gradation; but this is only half the truth, and we lack a still further requisite in colour-correct plates. Take a very common subject—for we all take our cameras to the seaside—sea, sky, and yellow sands. A photograph of such a subject is usually as flat and unreal as it can be; all the three divisions of our subject are rendered as if all one or nearly so, and any difference there may be is in the wrong place, sky may be a patch of white, and sand a dull, dark mass of uniformity. Looking from the scene to its transcript, you see these colour values exactly reversed. Hence are seascapes, unless enlivened by scudding clouds, breaking waves, or passing vessels, usually so tame and monotonous, and so unlike the reality.

Crookes', Vogel's, and Tailfer's Work.

Professor Crookes many long years ago found this photographic disability, and took the first step to remove it, by suggesting the use of a screen of light yellow glass, which depressed the blue rays and allowed the yellow to have greater effect on the plate. This was the first step towards what is now known as isochromatic photography. Many an old photographer has been an unconscious supporter of this principle when he has expressed his affection for an old lens which he has had in use for many years, the truth of the matter being that either the glass on the balsam, with which the combinations were cemented, or both, had become slightly yellowed by age, and gave him an improved rendering of his subject; but this was only less than half the battle, and, until plates were more sensitive to the rays at the other end of the spectrum, it was impossible to say that any approach to perfect colour-correct translation was obtained. Dr. Vogel is undoubtedly entitled to the credit of making the first suggestions and experiments with what may best be termed selective sensitisers; and, although his experiments were founded on wrong hypotheses, his methods were right. He was under the impression that dyeing the film was the only requisite; but it is manifest, in the light of our present knowledge, that this was only another method of using a yellow screen. The dye was more than that, and in fact altered, the colour sensitiveness of the silver salt. Dr. Vogel's experiments were made with collodion, and whatever was done in the same direction, if anything at all was attempted, with gelatine plates, was found absolutely ineffective until Tailfer took the matter in hand, and after years of elaborate experiments brought out his process, which forms the essence of the present-day system of isochromatic photography, as recognised now throughout the whole world.

Every attempt that ingenuity and money could suggest has been made to get behind his patent, but without avail. England, France, Germany, and America have all purchased his rights, and the only isochromatic plates that are made in the world to any practical extent are made under licence from him. Although, for over eight years now, the world of experimentalists have been at work trying all the dyes that recent researches have rendered available, every one has been forced to admit that the eosine group is not only the best, but the only one that will give practical and commercial results; and, further, that without the aid of ammonia even those eosine dyes are useless for practical work. No better proof of the stability of Tailfer's claims to priority and perfection could be given than this eight years of constant but unavailing endeavours on the part of scientific and practical men to upset his claims.

Practical Tests.

I may say that, in common with many others, I had a certain scepticism of the advantages of isochromatic methods until about a year ago, when, in an idle moment, I undertook to test the thing for myself. My first experiment convinced me of my error, and I propose to repeat that experiment to-night, as it seems to me the most conclusive argument that could be used in support of the advantages obtained by the use of "colour-correct" plates. This crucial experiment may be instructively extended, and in no direction more advantageously than in the combination of isochromatic plates with the use of yellow screens.

Such a scene as the seascape I have imagined, landscapes, with evening or morning light, where yellow tint prevails, views with hazy distance, and other similar conditions, render screens entirely unnecessary; but where we have ordinary landscapes, practically bathed in nothing but white light, then a light and correct screen is necessary. Even if there is a good deal of yellow or green in the subject, it will be so subdued by the flood of white light reflected from the surface of the various objects, that their intrinsic colours will have but little value to effect the plate. Screens, then, have their legitimate, and, we may even say necessary, use, for they serve to depress the blue rays without affecting the greens and yellows. In the experiment just carried out, it will have been seen that an isochromatic plate is more fully sensitive to the green and yellow rays, and less so to the blue, than the ordinary plate, whilst even in the red there is a slight advantage, for we see the isochromatic plate has a little detail where exposed under the ruby glass. We easily see from this how necessary it is for a proper and safe light to be used for our dark-room illumination. Yellow light is clearly quite unsuitable, and, even when we come to ruby, we must be careful to have a good ruby, and not too much light behind it.

Another example of the difference between ordinary and isochromatic plates may be further evidence of the advantages of the latter. Taking some slips of coloured paper arranged thus—orange, light yellow, dark yellow, light blue, dark blue—we find with an ordinary plate that the dark yellow and dark blue are rendered equally intense; the light blue is practically white, whilst the orange is made to appear lighter than the yellow. A print which I show will exhibit the falsity clearly.

The Yellow Screen.

Now, taking the same subject on an isochromatic plate, we have a much-improved result, the various intensities are more truly rendered, and when we examine the same subject, taken with a light yellow screen, we get absolute truth. It is apparent that we can go on increasing the depth of the screen, and get over correction, until the blues become too dark and the yellow quite white. It is of the utmost importance, therefore, to be sure that a screen of proper tint is used, where we do use one at all, and I may say that we shall take all responsibility off your shoulders in this matter, and supply such screens as will be just correct for the purpose, and no more. They will be of two shades; the lighter will need the exposure prolonged for two and a half times, the darker for five or six times. In order to avoid the necessity and expense of having a separate screen for each lens, they will be of such form that they can be

used for any lens. This is effected by using them in a specially designed simple frame behind the lens, so that the screen can be slipped in readily, and exposures made without trouble. This simplification will do away with one of the troubles attending the use of screens, and it will be as easy to take pictures with as without them. Of course, an extension of the time of exposure will be necessary, but, when we count our usual exposures by fractions of a second, twice or three times that will not be appreciably felt.

Another point about screens is this, they must be optically worked and free from flaws, otherwise we shall have distortion. It is quite plain, if the glass is wedge-shaped, that the rays will be interfered with; and, if the glass is either concave or convex, it will form a lens and interfere with the focus. It is wonderful how small a defect of this sort will throw the focus out to the extent of a quarter of an inch. If the screen has sides that are absolutely parallel, then we need not fear any danger. Even if the glass is not exactly parallel to the lens, no harm will be done beyond shifting more or less of the image out of the field, according to the angle at which the screen is inclined.

It will be seen, then, that the advantages of isochromatic plates under almost all circumstances are considerable, and, in many cases, they are incalculable. In dull weather, as in autumn or winter, the sensitiveness of isochromatic plates to yellow, greens, and orange gives them very considerable advantage over ordinary plates, both for outdoor and studio work, and enables shorter exposures to be given with improved truth of result.

In photo-micrography, in copying, in taking snow scenes, and in other special work, no other plates are permissible; and there is one other branch of photography that has made immense strides owing to these plates—I mean the photography of cloudland. The inherent difficulty of truthfully rendering the blues and whites has been a bar to progress, but with isochromatic plates all this is altered, and clouds are as easy to portray as any other subject. Still another point of advantage, found with isochromatic plates, is the greater freedom from halation.

Enough has been said to prove that "colour correctness" in plates is both a decided step forward in the art-science of photography, and a matter that is well within our reach without trouble or difficulty.

JOHN HOWSON.

Our Editorial Table.

THE "PHOTOGRAPHIC REVIEW OF REVIEWS."—No. 1.

Iliffe & Son, St. Bride Street, E.C.

THE new venture of Mr. Walter D. Welford reflects credit upon him for its neat *ensemble*. Its style might almost be deduced from its title. He selects the chief topics of the month from the various journals, and adds a few comments of his own, writing throughout in the first person singular. In a personal note Mr. Welford explains that he throws overboard the editorial "we," in order that the responsibility for the assertions made and opinions expressed may rest on himself or the writer. We learn that his connexion with journalism dates back to 1878. The "Review" contains several illustrations of hand-camera work, and other subjects.

SUTER'S CATALOGUE OF THE CARL ZEISS PATENT PHOTOGRAPHIC OBJECTIVES.

FROM Mr. J. R. Gotz, 19, Buckingham-street, Strand, we have received Herr Suter's new catalogue, and have also been privileged to examine several of the lenses catalogued. They cannot fail in proving useful, on account of their good definition and covering power, even with a large diaphragm.

PATENTS COMPLETED.

IMPROVEMENTS IN PHOTOGRAPHIC DEVELOPING TENTS AND CHANGING BAGS.

No. 20,864. WILLIAM RITCHIE BAKER, 9, Belmont-villas, Wallington, Surrey.—*December* 5, 1891.

MY invention consists of a shallow box of any convenient size, which is lined with waterproof material and fitted for use as a sink, water supply and drain pipes being attached if required. This is also provided with a stage or table of vulcanite of about the width of the sink, and of sufficient breadth at the top to prevent any liquid spilt upon it dripping into a fixing or other bath kept beneath.

The sides of the box are rather thick, so that a groove of about a quarter of inch wide by a half an inch deep can be sunk in their substance, which will contain a square of stout wire. The lid is formed of two doors, which open on either side, and have the outer ends supported by short legs, which let down when required. Two other squares of wire are made, but smaller than the first mentioned, so that they will lie in the tray when the apparatus is packed up. They are provided with feet, so that they can be fixed in an upright position at each end of the open doors.

A cover is now made of suitable non-actinic material, which will be fastened to, and kept extended by, these frames, and form a kind of waggon-head shaped enclosure, which will fold up and go into the box when not in use.

The middle parts of the long sides are fixed to two of the sides of the iron frame in the groove, and to the other sides of this, pieces of material are fastened, which extend to the bottom of the frames at the ends of the doors. White light is thus excluded, but the sink in the centre can be freely used.

At the bottom of one side the material of the bottom and sides is not joined, but is continued for about half a yard, so as to form a kind of sleeve, by means of which articles can be passed into or from the tent, without admitting light, if one end is closed before the other is opened.

In order to see within I make an opening just large enough to admit the eyes, and over this I attach a band with a corresponding opening, that fits closely to the face and fastens behind the head. Suitable sleeves are made for the hands, and covers are provided both for them and the eye-opening, so that the tent can be left and returned to without letting in the light.

When the sides are formed of more than one thickness of material, the inner ones can be arranged as curtains, so that the light may be regulated.

A head rest may also be provided if found necessary.

I do not confine myself to the materials or shapes mentioned in the above description, but would adopt any that would be most suitable for the purpose, and to secure greater portability when only a tent to change plates, and not to develop in, was required, would do away with the sink and box altogether.

IMPROVEMENTS IN PHOTOGRAPHIC PRINTING FRAMES.

No. 2934.—CHARLES CLOAKLY, 13, Northumberland-place, Bath, Somersetshire.—*December* 12, 1891.

AN improvement in the construction of printing frames used by photographers, consisting in the use of metal pins or wooden dowels, with or without metal plates, the object in using the said metal pins, plates, or dowels being to prevent the shifting of the photographic print during examination.

I also claim for the blackboards used to the said frames to be of two or more thicknesses of wood, the said wood to be glued or cemented crossways to prevent warping.

Claims:—1. The use of wood dowels or metal pins fitting into corresponding holes, with or without metal plates, the object being to prevent the photographic print from shifting during examination, as substantially before described. 2. The blackboards to be of two or more thicknesses, glued or cemented together, the object being to prevent warping, as substantially before described.

IMPROVEMENTS IN PHOTOGRAPHIC "SHEATHS" OR "CARRIERS."

No. 20,299. ARTHUR SAMUEL NEWMAN, 71, Farringdon-road, London, Middlesex, and ARTHUR LEWIS ADAMS, 81, Aldersgate-street, City of London.—*December* 12, 1891.

THIS invention relates to the carriers or sheaths used for holding and protecting the plates, films, or other surfaces for photographic purposes, both before, during, and after exposure, and my present improvements will be found especially advantageous for use with "automatic" cameras, and with changing boxes of all kinds.

For this purpose we arrange and construct a photographic "sheath" or "carrier" as follows:—

The top and bottom edges are turned over so as to embrace and hold the top and bottom of the plate, &c., and at each end neither edge thereof is turned up, but has a "set-back," or swelling on its back, formed thereon or therein in such a manner that it projects beyond the plane of the back of the sheath, and therefore the next plate, &c., behind same is thereby prevented from elsewhere coming in contact with such sheath, except at the extreme edge of each end.

If desired, the "set-back" may be formed in or on the top and bottom, and the two sides have their edges turned over, thus arranging the sheath *vice versâ*.

The sheath or carrier may be made of very thin sheet metal, or of any other suitable material or substance, and in place of the aforesaid "set-back" being formed out of the body of the sheath, it may be formed by attaching a separate piece—the same effect being obtained, and having the great advantage of having each side (or top and bottom, as the case may be) open, and thus allowing easy withdrawal or insertion of the plate, &c.; and also our present invention has this further advantage, that it can thus be made very light in weight, while at the same time having great strength, by reason of the two edges turned over in front, and the "set-back," or swelling on the back.

We further wish to remark that in some cases the "set-back" or swellings may also be formed on the back of the sheath, along the same edges as the turned-over edges, and the "set-back" or swellings on the two open sides dispensed with, or such "set-back" or swellings may be used on all four edges if desired.

Improved Means or Apparatus for Producing Artificial Light for Photographic and other Purposes.

(Communicated by Paul Nadar, 51, Rue d'Anjou, Paris, France.)

No. 3042. James Yate Johnson, 47, Lincoln's Inn Fields, Middlesex.—*December* 19, 1891.

This invention relates to the production of an intense white light suitable for photographic and other purposes for which a powerful light is required, as hereinafter described.

The art of photography would be capable of greatly enlarging the sphere of its operation as far as the production of negatives by the instantaneous process is concerned, and would be enabled to render novel and important services if means were provided for readily obtaining, at a given moment, a light sufficiently permanent and intense to enable it to be employed in place of the irregular and uncertain light of the sun.

Attempts have been made to employ magnesium for the purpose of producing a light of this description, but the apparatus heretofore employed with this object has failed to give satisfactory results. Lamps in which a coil of magnesium wire or ribbon is fed forward by clockwork or by hand are uncertain in their action, owing to the practical impossibility of accurately regulating the feed in accordance with the rate of combustion of the wire or ribbon, and present other disadvantages which form an obstacle to their successful employment.

In the "Helionocte," or apparatus arranged according to this invention, as hereinafter described, these disadvantages are obviated, and by causing a jet of air to throw finely pulverised magnesium into a flame, either intermittently or in a continuous manner, a very intense or powerful light is produced, which may be in the form of a flash or be maintained for any required period.

Any suitable flame may be employed to produce the combustion of the magnesium carried into the flame by the jet of air. In an apparatus in which the flame is produced by a spirit lamp, for example, a burner with a tubular wick is employed, and the receptacle for the spirit, which may be provided with a gauge-glass to show the level of the spirit, is placed upon a receptacle or chamber containing pulverised magnesium. In the bottom of this chamber, which may be removable, there is placed a nozzle communicating with a tube, through which air under pressure is supplied by a rubber pear with an elastic tube for regulating the pressure, or any other source of compressed air. Immediately above this nozzle is a short vertical tube, sliding telescopically upon a fixed tube extending into the central tube of the burner, where it is provided with another short adjustable or sliding tube. The space around the tube in the chamber or receptacle for the magnesium is charged with magnesium, and the jet of air from the nozzle in the bottom of the chamber draws in a quantity of the powder through the annular opening formed between the nozzle and the extremity of the lower adjustable tube, and carries it up the tube, discharging it at the upper extremity in the centre of the flame of the spirit lamp. The heat of this flame produces the combustion of the particles of magnesium suspended in the air, and a brilliant light is obtained. A trough containing water is placed at the bottom of the central wick tube (which extends through the spirit chamber) for the reception and extinction of any burning particles that may fall down the annular space between this tube and the central air tube. A removable plug below the nozzle enables the tube to be cleared if required, and arrangements may be made for charging the magnesium chamber with spirit chamber automatically or otherwise, and without interrupting the action of the apparatus. The quantity of magnesium thrown into the flame may be regulated by means of a screw plug or valve in the nozzle, or by varying the aperture of the nozzle. When this aperture is enlarged the space between the nozzle and the extremity of the tube should be diminished, and vice versâ.

The spirit lamp may be provided with legs engaging with corresponding sockets at the top of the magnesium chamber, or it may be constructed with a clamp pressed at the lower part to admit air to the flame, and arranged to screw on to the top of the box or chamber containing the magnesium. The air tube may be provided with a suitable cock or valve for shutting off or regulating the supply of air.

The flame may be produced by the combustion of gas, for example supplied by an ordinary burner, or a ring of burners, or a series of jets, in a chamber provided with a suitable air supply. These gas jets are situated under the lower extremities of vertical tubes passing through the top of the chamber. The products of gas and air combustion flow before it is delivered to the main tube at the point where the stream of air carrying the magnesium is delivered to the main tube at the point where. A plug burner may be employed to ignite the gas.

These arrangements may especially be employed to produce "searchlights," by causing the magnesium to be thrown into the flame intermittently or continuously, and may be combined with any suitable arrangement of reflectors.

In order to obtain a shorter and more concentrated flame, I prefer to surround the apparatus with a funnel or chimney, carried by a vertically adjustable tank plate, connected to a horizontal plate or table, forming the base of the apparatus. A rack-bar is attached to the back of the tank, and acts as the support to a vertical plate, preferably of steel, having its lower part bent forwards, so as to form a shelf in horizontal flange. Beneath the spirit vessel is a water trough to catch the sparks, and below this is fixed to the said vessel is a receptacle for gunpowder, provided with suitable arrangements for producing a flash or explosion at any time, with regulable or intermittent action, for the flame of the spirit lamp. The flame is blown back by the current of air and incandescent matter into the pile of the tank, being prevented from spreading outwards by the overhanging flange.

In place of the magnesium, any other material capable of producing the effect hereinbefore described may be employed, and any suitable gas or liquid may be employed in place of the air for carrying the said magnesium or other material. Oxygen gas and hydrogen gas may be employed, for example, in an apparatus arranged according to this invention.

An Improved Photographic Vignetting Attachment.

(Communicated by Amos J. Lamborn, William Nuneviller, and William Koebler, jun., all of Philadelphia, in the State of Pennsylvania, United States of America.)

No. 19,767. William Wilson Horn, 151, Strand, Middlesex.—*December* 19, 1891.

This my invention relates to an improved photographic vignetting attachment, and my invention consists in forming a vignetting attachment of *papier maché*, paper-pulp, or other plastic material, moulded or pressed into shape, making a light, cheap, and durable article.

It also consists in setting out the face of the attachment so that increased strength is obtained, and the light may be diffused to a greater extent, and the vignette thereby made softer.

As the attachment is formed by pressing, stamping, or moulding, it is cheaper and lighter than heretofore, and possesses increased strength.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—1. A vignetting attachment for photographic printing frames, formed of plastic material, having its face set out, said face portion being integral with the attachment, substantially as described. 2. A vignetting attachment for a photographic printing frame, formed of plastic material, pressed or moulded into shape, and having its face set out, said face portion being integral with the attachment, substantially as described. 3. A vignetting attachment for photographic printing frames, consisting of a piece of plastic material pressed into shape, and having an integral inclined face, substantially as and for the purpose set forth.

[We need scarcely say that this invention has *long* been familiar to our readers, thanks to Messrs. Lyonel Clark, George Mason, and others. —Ed.]

Collapsible Background for Photographic and Other Purposes.

No. 20,302. Franz Wiese, 19, Steglitzer-strasse, Berlin, Germany.—*December* 24, 1891.

For painting and photographic purposes a background for limiting distances is often requisite. It is easy to obtain such a background in studios or in dwelling-houses, but outside it is a matter of some difficulty, as high stretched wooden frames cannot be readily transported, owing to their great weight and awkward form.

This invention will remedy these defects by the construction of a collapsible frame, which may be set up and covered with the material used in any suitable part and place.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
February 1	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
" 1	Halifax Camera Club	
" 1	Peterborough	Museum, Minster Precincts.
" 1	South London	Hanover Hall, Hanover-park, S.E.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

January 26.—Technical Meeting, Mr. W. Bedford in the chair.

Mr. Pope, the delegate of the Photographic Society of India under the affiliation scheme, was present.

Mr. A. Cowan exhibited Messrs. Harter & Driffield's "Actinograph," the use of which he explained. He mentioned that he had some months ago exposed plates based on the calculations of the instrument, and could not have found it act better by any amount of experience. One of Mr. Driffield's employés at Widnes, who knew nothing of photography, simply by following the instructions given, produced a large number of negatives, nine out of every ten of which would

have shamed any professional. For studio work the actinograph had been found correct.

Mr. J. R. Gotz exhibited his new film carriers available for use in the ordinary dark slide. A short fold on the carriers in the form of a spring keeps them in their place. In an ordinary double back the division may be dispensed with, and as the carriers, being made of thin sheet iron, are extremely light, a back loaded with carriers and films is, perhaps, not heavier than the back with a division.

In connexion with the subject for the evening, *Printing-out Emulsion Papers*, Mr. Gotz toned and fixed a number of pictures on Obernetter's matt surface gelatino-chloride paper. In the course of his remarks he mentioned that it was not necessary to print so deeply as on glossy surfaced papers. There was more detail in the shadows, and finer detail generally. He had known such paper to keep well for five years. Platinum toning was uncertain.

Mr. J. Howson next toned and fixed several prints on the new Ilford gelatino-chloride paper, accompanying the demonstration with a description of the toning and fixing baths recommended, and the manipulation of the paper generally. In reference to the keeping qualities of the paper, he mentioned that some of it had gone on a voyage to the West Indies and back, and remained in an excellent state of preservation. He thought the paper was best kept under pressure.

At the conclusion of Mr. Howson's demonstration, both he and Mr. Gotz were thanked by the meeting.

Mr. A. Mackie drew attention to the new methylated spirit regulations, and suggested that the affiliated Societies, in conjunction with the Photographic Society of Great Britain, should approach the Inland Revenue authorities, with the view of securing some modification of the regulation. It might be possible that the methylators should be allowed to sell quantities of not less than two gallons of the old spirit to authorised persons.

After some discussion on the subject, it was agreed that the matter should be brought before the affiliated Societies at the meeting about to take place.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

January 21,—Mr. J. Hay Taylor in the chair.

A question from the box was, "What is the specific gravity of one part of ammonia ·880, and nine parts of water?"

The answer as given by Mr. Bedford, jun., was ·988.

Mr. W. E. Debenham said that this was assuming one part added to nine made ten parts by bulk. If they added, say, one part of alcohol at ·880 to nine parts of water, they would certainly not get that result.

Mr. J. S. Teape said that he had developed a weakly printed gelatino-chloride print with gallic acid as directed in The British Journal of Photography, of December 4, 1891, but the picture took two hours to develop. He used six per cent. of a saturated solution of gallic acid. He had washed out the free silver before development.

Mr. Debenham thought this should not be done, and recommended the addition of acetic acid to the developing solution.

Mr. Teape also stated that with reference to Mr. W. Bolton's method (published in The British Journal of Photography) of getting rid of the mineral naphtha from the new spirit, namely, the addition of five grains of permanganate of potash to the ounce, he had tried it, and found the permanganate did not remove the mineral naphtha at all. He (Mr. Teape) remarked that Mr. Bolton himself did not make the experiment with the commercial spirit, but that made with the addition of benzoline, which might be quite another thing. The permanganate of potash dissolved in the spirit, but after a few minutes formed a heavy precipitate, which when removed left the spirit in its original state, as he found that with the addition of water it went milky as usual. He judged that there was thus no alteration in the alcohol.

The remainder of the evening was devoted to a lantern entertainment, the slides being contributed by Messrs. G. W Atkins, T. E. Freshwater, Beckett, Rawlings, J. Weir Brown, Kellow, L. Medland, J. S. Teape, Cole, and W. Bedford.

Camera Club.—January 21.—Mr. Alfred Maskell read a paper on *Photography and Arrested Motion*. Mr. F. Machell Smith occupied the chair. The Lecturer assailed the results of a large proportion of the instantaneous photography practised as giving only inanimate pictures, and incited to the use of methods and treatment which would better suggest a sense or idea of action and motion. A large number of illustrations were given, and the lecture excited a discussion, in which the Rev. Lambert, Messrs. Humphery, Fison, Patterson, Harrison, Davison, Davis, and the Chairman took part.

Lantern Society.—January 25.—Mr. C. F. Budenberg, of Manchester, read a paper, *On Pressure Gauges* [see page 70].

North Middlesex Photographic Society.—January 25, Mr. H. Walker in the chair.—A large collection of slides were shown by Messrs. Ainsley, Cherry, Gill, Gregory, Johnson, Jones, Marchant, Mummery, Plunkett, Smith, Taylor, Treadway, Wall, and Walker.

West London Photographic Society.—January 22, Mr. C. Bilton in the chair.—Mr. J. D. England read a paper on *Celluloid Films* (this will appear in a future number). The Lecturer described celluloid, and explained its manufacture, showing samples of clear and matt celluloid, such as is used in manufacturer's negative films, and also a specimen of ivorine. He explained the advantages of celluloid over glass for negatives, and showed carriers for holding the films in the slides, and a changing box. He then explained the necessary steps to be taken in developing, fixing, washing, drying, intensifying, reducing, and varnishing. He showed several specimens of negatives, and two exquisite stereoscopic positives on celluloid. The paper was followed by a discussion.

South London Photographic Society.—January 18.—The principal feature of the programme was an exhibition of dioramic effects in the triple oxy-hydrogen lantern, given by Messrs. Banks and Greaves, consisting of statuary, views, &c., which showed clear manipulation of the lantern, and included the fountains and illuminations at the Inventions Exhibition, the castle of St. Angelo, Rome, and Milan Cathedral by day and night, and last, but certainly not least, the progress of a memorable fire in Cheapside, which was received with loud applause. The last was a very interesting specimen of the photographic art, and one of the best in Mr. Banks' numerous collection. During the evening a selection of vocal and instrumental music was given. Miss Ella Thompson and others contributed songs. The duties of accompanyist were performed by Mr. Lewis Devaux. An exhibition of microscopic objects by members of the South London Microscopical and Natural History Club were much appreciated.

Brixton and Clapham Camera Club.—January 21, Dr. J. Reynolds in the chair.—The subject for discussion was *Printing Processes*, to which two excellent papers were contributed by Mr. F. Goldly and the Hon. Secretary (F. M. Levett), the former on *Plain Salted Paper*, and the latter on *Carbon Printing*. To illustrate his remarks, Mr. Levett developed two prints, which had been kindly sent down ready exposed by the Autotype Company. A number of photographs of the recent earthquakes in Japan were handed round for inspection by Mr. Burrows. Mr. Andrew Pringle will deliver an address at the next meeting on the 4th proximo.

Croydon Camera Club.—January 18.—Lantern evening for members' slides About two hundred slides, the work of Messrs. Hirst, Isaacs, Holland, and White, were submitted for inspection.

Bristol and West of England Photographic Association.—January 22, Mr. Brightman in the chair.—Mr. Hemmons read his notes on the proposed photographic survey of Bristol and neighbourhood. After discussion it was decided to form a Provisional Committee to allot the various portions of the work in the district and to make all other arrangements. Mr. Brightman then gave his paper on *Lantern Slides, and How to Make Them*, showing some lovely slides. He developed some carbon slides, illustrating a process which seems very seldom worked, although giving such fine results. The next meeting will be on February 12, when Mr. Harvey Barton will lecture on *Flashlight Pictures*.

Bristol Camera Society.—January 22.—The set of lantern slides, *Boston Illustrated*, sent over by the American Photographic Society, were exhibited by Mr. Dunscombe with a limelight lantern. A resolution was carried that the members prepare a set of slides illustrating Bristol for loan to the American societies.

Oxford Photographic Society.—January 19.—Mr. Frank Howard, of the Camera Club, gave a lecture on *English Pastoral Landscape*. The lecture was illustrated with numerous slides, many of them having been made from negatives taken twenty-five years ago. Nearly all the views were taken within twenty miles of Oxford, and clearly showed what simple bits of scenery will make a "picture" when a photographer knows how to select and photograph the view. Those in which were cattle, were especially fine. Twenty members and sixty visitors present. February 2, *The Oxford Photographic Society: What it has, and might have, Done, and should Do.*

Lewes Photographic Society.—January 19.—Several slides by Messrs. Braden, Bedford, Constable, Currey, Morris, Turner, and Wightman, were shown. The subject of the next quarterly competition, *Leafless Trees*, was announced. At the next meeting, on Tuesday, February 2, Mr. G. I. Wightman will read a paper on *Platinum and Bromide Printing: a Comparison and a Contrast.*

Tyneside Camera Club.—January 19. Mr. J. F. McKie (President) in the chair.—The President gave a lecture on *Enlarging, Copying, and Reducing, and the Apparatus for so doing.* He drew the attention of the members to Messrs. Griffith's apparatus for enlarging and reducing. He also described the various copying apparatus, and gave directions for getting the best results, and for preventing the grain of the paper from showing in the negative by means of reflectors. The lecture was illustrated by numerous diagrams.

Glasgow Photographic Association.—January 21, Mr. J. Craig Annan (Vice-President) in the chair.—The President, Mr. Wm. Lang, jun., F.C.S., delivered a lecture on the *South End of Arran*. The lecturer gave an account of the early history of this portion of the island, and showed, by means of the limelight, a large number of views. The following is a synopsis of the lecture: Early History and Writers—Monro, Martin, Pennant, and Headrick. Druidical Remains—Brodick, Brodick Fair, Lamlash, Holy Isle, and St. Molios, King's Cross. Bruce and Arran—Whiting Bay, Glen Ashdale, Dippin Point, Ailsa, Kildonan Castle, Signal Station, Pladda, and Benan Head.

Glasgow and West of Scotland Amateur Photographic Association.—January 18.—Mr. John Morrison, jun., occupied the chair until the election of Mr. Thomas Taylor as President of the Association. The Secretary read the Council's report for the past year, wherein it was stated that forty-four new members had joined the Association during the year, and that now the membership was 212. The Treasurer's financial statement showed that after providing for all debts there was a substantial balance at the credit of the Association. The members of Council for the coming year having been elected, there was a discussion on the new "Rodinal" developer, followed by the usual show of lantern slides.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

ENLARGED VIEWS BY ONE OPERATION.

To the Editor.

Sir,—My attention has been called to a long correspondence in your Journal between Mr. Dallmeyer and my old friend Dr. Miethe, of Potsdam, regarding a new (?) form of photo-telescope, which they claim to have invented, and also to your criticism thereon. While I have no

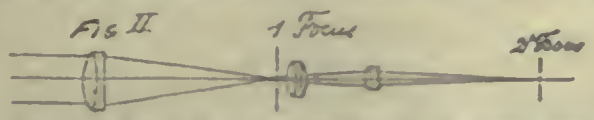
doubt these gentlemen fully believe their discovery is novel, I feel sure they will both be satisfied that they have been anticipated when I refer them to what I have myself done in the way of direct enlargement of images of different sizes by one operation through the knowledge I obtained from the plain instructions given in the works of Sir John Herschel, Peter Barlow, and others.

In the years 1869–70 I was engaged in constructing a large refracting telescope for astro-physical purposes for Baron von Bülow's observatory at Botheamp. Before erecting this telescope permanently at Botheamp, I had it set up under a temporary dome in my garden at Hamburg, for the purpose of trying known methods for direct enlargements by one operation. I was quite aware, from optical theory and from what had been already published, that this could be done either by negative or positive lenses used in conjunction with the objective; but, in order to judge which form of lenses gave the best results, I carried out both methods.

Negative Method (Fig. 1).—I used a threefold cemented achromat, about two inches in diameter and eight inches negative focus, and found this produced a powerful and well-defined image on the screen, and, by moving this negative lens along the axis of the telescope, I was able to

alter at will the size of the image thus obtained from a distant object. The objects principally operated upon were the moon, sun spots, and other celestial bodies, and I also tried it on the tower of the water-works at Hamburg, which was the only available object of which I could command a view.

Positive Method (Fig. 2).—I used a system of two positive achromats distanced for flatness of field, but not so far apart that the equivalent lens became negative. This method did not give the same definition or so flat a field as in the first arrangement with the negative achromats; but Dr.



H. C. Vogel, the astronomer, found it convenient, as it enabled him to use it in connexion with cross wires, or micrometers, which he could not use with the negative system. Of course, a wooden camera and screen was attached to the instrument in the usual way.

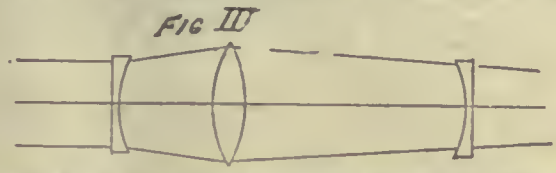
Before the instrument was removed to Botheamp, Mr. Höge, photographer of Hamburg, was occupied for a considerable time in taking enlarged photographs of the objects mentioned in different sizes by one operation, using the wet-collodion process then in use, and a great advantage was at once seen, as the structure was not interfered with by any deposit, which would have been the case had a small photograph been first taken and enlarged afterwards. This method of enlarging created considerable interest in Germany at the time, and Dr. Hermann Vogel (editor of the *Photographic Journal of Berlin*) paid me a visit to see the arrangement, and a photograph of the moon was taken in his presence by Mr. Höge, and he gave a long account in his journal of what he saw—I believe early in 1870.

On the completion of the telescope, Baron von Bülow deputed Doctor H. C. Vogel, the astronomer, to inspect the instrument and photographic arrangement. This gentleman expressed himself greatly satisfied with the results obtained, and he himself afterwards used the instrument at Botheamp very successfully in photographing the sun and other objects, which were shown to a large number of *savants*, amongst whom were several American astronomers and Doctor Huggins, F.R.S., who took great interest in the matter. The instrument, with its enlarging apparatus and camera attached, is still doing excellent work at Botheamp Observatory.

Some two or three years after this I constructed smaller instruments, for direct enlarging by one operation, to be used at the transit of Venus. These were employed with great success, and the results published in the German astronomical papers at the time.

As regards the original idea of direct enlargement by one operation, so far as I can judge, the negative *achromat*, used in the manner I have described, is the invention of Peter Barlow, who improved on Wolf's original system. See the *Telescope*, by Sir John Herschel (1861), page 50.

Doctor Donders, Professor of Physiology in Holland, also invented a system of three lenses, which can be used for enlarging direct by one operation, and which has been treated exhaustively in a paper by Professor J. A. C. Oudemans, Director of the Observatory at Utrecht, *Théorie de la Lunette Pancratique de M. Donders*. Professor Oudeman's formula shows two different arrangements of construction. The first



has two negative lenses outside and one positive lens inside (Fig. 3); and the second, two positive lenses outside and one negative lens inside (Fig. 4).

I may mention that, some few years ago, I constructed a gun-director telescope for Messrs. Ross & Co., for use in the Royal Navy, the principle of which would be equally suitable for producing enlarged photographs of various sizes by one operation.

I would add, in conclusion, that the principle of direct enlarging can be carried out partly or fully by reflectors.—I am, yours, &c.,

London, S.W., January 20, 1892. HUGO SCHROEDER.

[Dr. Schroeder is certainly to be congratulated upon the completeness of his researches in this direction, and, having reference to the dates given by him, he must, in the race for priority, be held as coming in an easy first.—ED.]

THE TELESCOPIC-PHOTOGRAPHIC LENS.

To the EDITOR.

SIR,—It appears that the idea of employing a Galilean telescope for the formation of images visible upon a screen dates further back than eighteen years ago. Nevertheless, the ground you take up, and upon which I shall meet you, is the matter of your own publication of eighteen years ago.

At that time, by your own confession, you were honestly (and naturally too) disappointed with the results; and, moreover, you confirmed this disappointment by a suggestion for an improvement by employing a negative lens of Petzval's "orthoscopic" form. It is not my intention to criticise the said suggestion, in that you have left the theoretical aspect of photographic optics to others. In the conclusion of your article of eighteen years ago, you appeal to such others to see if a combination could not be made to accomplish the end in view! Since that time, to the best of my knowledge and belief, no one had succeeded in accomplishing the end in view until I did so. Should Mr. Jarret's instrument be made on the same principle as my own, I shall be surprised, in that his most recent publication (in the *Photographic Gazette*, and referred to last October in the *Photographic News*) to attain the same end is distinctly a retrograde move; and, moreover, one well known to have been employed for solar photography for many years. Mr. Jarret's instrument, referred to by you, is not, however, described.

As to your remarks upon using one optical instrument for a different purpose to that for which it was originally constructed, I fail to find any hit. To take your own ground again, I ask, Was my late father's "triple wide-angle landscape lens," composed of three cemented lenses a valid patent? And yet, Sir, doubtless the triple-lens opera-glass front combination may have been, and probably was, used for photographic purposes as a makeshift!

The extreme limit of the appreciation possible, to a mind not fully at ease in theoretical matters, one could not expect to take any other form than the remark, "The new lens may be an improvement."

I "was taken by surprise" at the Camera Club, and had reason to be, after your previous attitude to me personally, and also as Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY, in the controversy with Dr. Miethe, as set forth in my letter of the 8th inst. The surprise was not, however, prompted by the feelings you ascribe to me; the fact was, I could not have believed it of you, after the events of the previous few months referred to. It was a personal matter for surprise!

I need not reply *re* the small camera further than remind you that, when you describe instruments, and refer to a field being sharply covered as "small," it is misleading, unless definition at the margins of the field is destroyed. A more intelligent and applicable expression would be to state that the *angle* included is necessarily small. At the Camera Club, the negatives shown were taken upon "half-plates," with an extension of camera of thirteen inches (they might have been taken even on "whole-plates"), but this is a detail.

I still await the results of any further search you may make to show

that, with regard to this "improvement in photographic lenses," that some other investigator preceded me in making "a silk purse of a sow's ear." If you can do so, I trust I can appreciate the work of another as well as my own, and it would not be my object to "damn it with faint praise."—I am, yours, &c., THOMAS R. DALLMEYER.

25, *Newman-street, Oxford-street, W.*

[We are content to leave this matter as it stands at present, the more especially as Mr. Dallmeyer will find his concluding aspiration fully realised in Dr. Schroeder's letter, which precedes this.—ED.]

RATIO OF GRADATION.

To the EDITOR.

SIR,—Mr. J. R. Hopwood, Ph.D., in your last number calls attention to the fact that the investigations of Messrs. Hurter & Driffield appear to be quite ignored by photographers, although their principles, if satisfactorily established, would entirely revolutionise present ideas in regard to development. A careful study of the paper on *Photo-chemical Investigations*, by those gentlemen, will satisfy most readers that there is much force in the arguments there used, in which they endeavour to prove that the composition of the developer has no influence on the gradation of the resulting negative, but, at the same time, the experiments on which the new theory is founded seem scarcely exhaustive. Only small differences in densities were examined, viz., those produced by exposures of between ten and eighty of the units adopted, and these densities probably would not have sufficient contrast to show small variations clearly, especially as so much allowance has to be made for errors of experiment. They were also probably all included in the "period of correct exposure," in which, as the experiments show, progress is very regular. Whether conditions which apply to such densities would also be true at the extreme ends of the scale of exposures has yet to be proved. As regards these densities, however, all the developers tried, viz., pyro, hydroquinone, eikonogen, and ferrous oxalate, certainly gave very similar results, but they appear to have been generally mixed in about the normal working proportions, and only two experiments are mentioned in which these were departed from. In the first case the only alteration was that the usual quantity of ammonia was added to the pyro developer in six separate doses instead of at once, and in the other the amount of bromide was varied. The compositions of these developers are not given, but in the last case (cap. 16), judging from previous experiments, it would probably work out in English weights and measures as per ounce, pyro, 1½ grains; ammonia, 880° 2½ minims; bromide of ammonium, 3 grains. The results produced by this mixture are shown to be nearly identical with those produced when only one grain of bromide per ounce was employed. But much greater variations in the proportions of the ingredients are used in practice when trying to correct over-exposure on the one hand, or under-exposure on the other. The experience of many workers and experimenters is contrary to these conclusions of Messrs. Hurter & Driffield, so I think we must wait for further knowledge before entirely accepting them; still, there is clearly much in them that is true, although exceptions and modifications may have to be made.

Mr. Hopwood's account of the new principles is, I think, likely to be misunderstood. All that he states as to the proportionate increase of *density* in different parts of a negative during development is quite right, but *only* when using that expression *in the sense adopted by Messrs. Hurter & Driffield*, viz., as representing the amount of reduced silver in the part examined. But among photographers *density* is usually taken as meaning *opacity*, and in that case the principles are quite different. Opacities of 1 : 2 *might* by more prolonged development be changed to 1 : 3, but what is asserted is that the relations are so fixed that all other ratios would then change according to an unalterable rule. If any three parts of a negative under development had opacities in the geometrical ratios of 1 : 2 : 4, then further treatment might change the series to 1, 3, and 9, but never to 1, 3, and 8, for instance. Mr. Hopwood uses an argument which might appear to apply here, and it might be asked how, if in one part of the plate the opacity increased from 2 to 3, in another where it equalled 1, it could remain unchanged; but it must be remembered that, by Messrs. Hurter & Driffield's definition, an opacity of 1 means no opacity at all—it represents only the bare glass of an unexposed part of the plate.—I am, yours, &c., H. J. CHANNON.

Woodlands, Lewisham, S.E., January 25, 1892.

THE ORIGINATOR OF THE GELATINE PROCESS.

To the EDITOR.

SIR,—In reply to Mr. Bolton, on the originator of the gelatino-bromide process, will you allow me to say that it is the truth I am contending for, not the testimonial? I plead for justice, not charity.

I will confine myself to what is claimed for Dr. Maddox, namely, that "he was the first to publish a practical and workable formula." If this were true, I should be disposed to contribute a mite to the testimonial myself, but I know it is not true, and feel it to be a very unpleasant duty to say so.

I confidently affirm, and am prepared to prove, that Dr. Maddox never published what can with truth and fairness be described as a *practical* and *workable process*. The experiment he did publish was by no means the first record of an attempt to use gelatine as a substitute for collodion. Gaudin, Harrison, Kennett, and many others, were before him; but one and all failed to overcome difficulties which beset them, and neither of them made a useful gelatine plate—that is, one that would hold its own against collodion; consequently, they all sank into oblivion, without attracting the slightest notice from practical men or, indeed, from any one. The results were so discouraging that no one dreamt of repeating the experiments. There was no sign or hint of any advancement in the art of photography. An experiment that reveals no new truth is valueless.

What did Dr. Maddox discover? He says himself there was nothing new in what he did, and there was not an idea or hint of any kind that could be of the slightest use to any one who wanted to do something better in photography than had been done before. Infinitely better work could be done by the old processes. The gold-medal formula was a hap-hazard jumble of chemicals that no practical man ever did use, or could be induced to use. It was not capable of producing a decent print, which it was designed for, much less could a negative be got out of it, and yet it is, according to Mr. Bolton, a practical and workable process. But a stronger condemnation of the formula is found in the fact that its author immediately forsook it, and the negatives which were exhibited by Dr. Maddox must have been taken by some other process, which he never published. Indeed, we have his own word for that.

Mr. Debenham, with great astuteness, informed a meeting that he had taken negatives by Dr. Maddox's formula with a *modification* of his own. Then it was the modification that did it; and I call it a subterfuge, especially when no particulars are mentioned, to give a fictitious value to a worthless thing.

Mr. Bolton ought to know that there was no practical and workable gelatine process in the world till 1873. No process up to that time had appeared which made the smallest pretentions to compete with collodion, and until my discovery was announced gelatine was of no account. It was my honour to be the first to demonstrate that gelatine was not only equal to, but superior to, collodion for plate making, and, though I never published a formula, experimentalists fastened such a grip on it, that from that day to this they have never let it go.—I am, yours, &c.

Packham, Jan. 25, 1892. J. BURGESS.

CYLINDERS AND GAUGES.

To the EDITOR.

SIR,—Mr. G. R. Baker struck the true note when he said the hap-hazard way of making wonderfully cheap apparatus was the bane of limelight work, and I am sure no one who knows anything about the matter will quarrel with me when I say that in no department is it to be more censured, because of the danger, than in cylinders and gauges, and a remedy for the evil is imperative.

My experience in these matters goes back to the days before Brin's patent, and before the days when cylinders were turned out by the thousand; and when I compared the careful, scientific, and accurate manner in which cylinders in those days were tested with the slipshod, happy-go-lucky mode in vogue from four to two years ago, during which period the bulk of the cylinders now in use were made, the matter for surprise is not that the mishaps are so many, but so few. The same remarks apply to gauges.

But that the *principle* of Bourdon gauges is good, and that they can be, and are, made of the highest quality, facts like the following prove:—About five years ago Messrs. Schaeffer & Budenberg made for me a gauge sealed up to 6000 pounds to the inch; it is unencumbered with check valves or any other complication, and is as good now as the day it was made, though I have gauged with it upwards of 18,000 cylinders, oxygen, coal gas, and hydrogen, one after the other, in any rotation, often as many as fifty in one day. The only precaution taken was to wash the tube out well in the first instance with ether, and then keep it clean. The last time it was compared with a standard gauge, the registration had not varied even to the breadth of the pointer.

So long as poor, cheap cylinders and gauges are made, so long will there be found persons ignorant enough to purchase them. I am no advocate for the interference of Parliament, but wish to suggest what I think would be a very effectual remedy, if only it can be brought about. It is this: That the Photographic Society of Great Britain, as the parent Society, prepare a memorial for presentation to the Kew Committee of the Royal Society setting forth the dangers of using unreliable apparatus, and praying them to add to the Kew Observatory a department for testing high-pressure cylinders and gauges; and that this memorial should then be sent around to every photographic society to be signed by president or secretary on behalf of each society.

As among the members of the Photographic Society of Great Britain are several members of the Royal Society, one, at least, of whom is on the Kew Committee, a ready and influential means of communication between the two societies is already provided; and I venture to think a memorial backed up by the entire body of users of the apparatus in question throughout the country would not be without weight with the Committee.

Once get the department established, the rest is easy; it will be only necessary for every user to refuse to receive any cylinder or gauge that

does not bear the Kew monogram, and makers will not be long in sending their apparatus to be tested.—I am, yours, &c., EDWARD J. SMITH.

Park-royd, Halifax, January 25, 1892.

To the EDITOR.

SIR,—In a lecture by Mr. H. M. Whitefield on *Pressure Gauges*, which appears in the current issue of THE BRITISH JOURNAL OF PHOTOGRAPHY, I notice a reference to a description of an arrangement of Mr. Beard's for checking the too sudden entry of gas into gauges when used for testing high pressures. This evidently is taken from a report of one of this Society's meetings, where the said arrangement was spoken of, and my purpose in writing is to point out that Mr. Whitefield's non-understanding of the description is probably due to the condensation necessary in such reports, it being only practicable to deal with such matters in general terms. Mr. Beard's plan, as understood by myself and, I think, the other members who were present, is to insert in the entrance to a gauge a screw plug, practically closing the passage, but having the screw-threads so cut (a simple matter) as to allow gas at high pressure to pass slowly along the course of the thread to the gauge. All who have worked with gauges or regulators know that, however accurately the screw unions may appear to fit, the gas will leak past the screw unless the union is forced tightly home upon the seat, a washer being inserted to ensure a sound joint. It is this screw leakage which I understand Mr. Beard has taken advantage of to produce the gradual filling of the gauge, and it appears to be a practicable way of meeting the difficulty.

Mr. Beard is quite able to look after and to support his own interest in the matter, but I should not like a probably valuable arrangement to suffer by any apparently inaccurate or incomplete description.—I am, yours, &c., WILLIAM BISHOP,

Hon. Secretary North London Photographic Society.

January 26, 1892.

MIDLAND COUNTIES' POSTAL PHOTOGRAPHIC SOCIETY.

To the EDITOR.

SIR,—It is proposed to form a "Midland Counties' Postal Photographic Society" if a sufficient number of amateurs are found favourable to the movement, amateur photographers only to become members.

The principal object of the Society would be the monthly circulation of photographs (in albums or portfolios), accompanied by a note-book for criticism of the prints, and the award of moderate prizes for the two best in each set, the awards to be made by the votes of the members and recorded in the note-book.

It is proposed at present to confine the Society to the Midland Counties, and the number of members to fifty, as by that means the district will be compact and the circulation of parcels prompt and inexpensive.

Working details will be submitted later (for discussion) if it is found that sufficient names are sent in support of the idea.

The number of members admitted should be proportionate to each "County District" if there are sufficient applications from each district; if not, vacancies can be filled up from any other district.

Sizes of photographs to be from half-plate to 12 × 10 inclusive, and to be printed only in some permanent process, as platinotype or carbon.

A President and "General Secretary" to be appointed, and "District Secretaries" in each county, who would form a Committee of Management.

It would be pleasant, if possible, to have each year a "General Meeting" in the various districts alternately at a time of the year when the members could combine business, out-door photography, and social intercourse, so as to form an agreeable excursion under the guidance of the Secretary for that district.

Applicants for election to submit prints (when required) as proof of their photographic ability, for the inspection of the Committee (when formed), the *quality* of the work to form a guide as to precedence for election.

Ladies and gentlemen wishing to support the movement are requested to send their names and addresses (provisionally) to—

West Walk Leicester. GERMAN BANKART, *Hon. Secretary pro tem.*

TYLAR'S FILTER.

To the EDITOR.

SIR,—As agent for the Company who have introduced an improved, also economical, filter, I desire your indulgence in replying to Mr. Henderson's letter in to-day's issue. He tests and compares the merits and cheapness with something he purchased ten years ago, and which he personally improved upon by his own ingenuity; but I assume he has not purchased one of the form now issued, merely going by a paper description. This is not fair. Again, if the public were all of Mr. Henderson's calibre, many substitutes might be made for what is sold to-day. For instance, cameras of highly finished mahogany are no better for the purpose required than light-tight cigar-boxes. Further, I must thank Mr. Henderson for admitting the benefit by using a cheap filter for many years, although he carps at the novelty clause and a difference in price of 9*d*. Surely this is a trade matter. If he can make a filter of metal, indiarubber, charcoal, sponge, &c., as convenient and as good as that now put upon the market, without infringement, the world is open to him, and I fail to see the reason of his letter. In conclusion, I would remind your correspondent there is nothing new under the sun, and what was sold to him ten years ago may be improved upon and sold to-day as a novelty to a younger generation troubled with influenza.—I am, yours, &c., W. TYLAR.

Birmingham, January 22, 1892.

URANIUM TONING FOR PLATINUM PRINTS.

To the EDITOR.

SIR,—I have not seen it mentioned in connexion with the uranium toning bath that it tones platinum prints—hot and cold bath—equally well as bromide prints. This I find to be so, and that avoids the necessity for using the sepia paper.—I am, yours, &c., LOUIS MELDON.

Dublin, January 25, 1892.

STRAIGHTENING OF CURLED FILMS.

To the EDITOR.

SIR,—In reply to your correspondent, Miss May, re the straightening of curled films, we have a great experience in developing these films, and can recommend the following:—Soak the films for an hour in water, then place in a weak solution of glycerine, one part glycerine to thirty parts of water for five minutes, and pin down on a board, with film side up; in about twelve hours they will be dry, and in perfect condition for printing, though, when not in the printing frame, they must always be kept under pressure.—We are, yours truly, &c.,

Hampstead, January 25, 1892. THOS. ILLINGWORTH & Co.

OWNER FOR A CAMERA WANTED.

To the EDITOR.

SIR,—A box containing a camera and some other things, has been sent to us apparently in mistake. The Company know nothing of it, and have not received any communication about it.

The box was addressed to us in pencil written on the wood, but there is no indication whence it came.—We are, yours, &c.,

Watford, January 25, 1892. PAGET PRIZE PLATE Co.

CAMERA CLUB FIXTURES.

To the EDITOR.

SIR,—In consequence of Mr. Willis's absence abroad, his paper already announced to you for February 4 at the Camera Club is postponed, and the evening will be devoted to *A New Enlarging Lantern*, and demonstration, by Mr. S. Herbert Fry.—I am, yours, &c.,

G. DAVISON, *Hon. Sec.*

Camera Club, Charing Cross-road, W.C., January 26, 1892.

Exchange Column.

**** No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Wanted, to exchange a background, new, never used, for cabinet camera and lens.—Address, T. CLARKE, 27, Kingsland-terrace, York.

I will exchange a landscape lens, covers 8½ × 6½, for a rustic chair, or two single lenses for studio accessories.—Address, FRED. C. D. HEAD, Photographer, Shepton Mallet.

Wanted, 10 × 8 rapid rectilinear tight whole-plate camera or hand camera; exchange, Oakley's patent metamorphoser magic lantern and slides.—Address, COUCH, 11, Waterloo-crescent, Dover.

Wanted, 8½ × 6½ wide-angle rectilinear lens in exchange for balustrade, pedestal, large rock, cork floor stand, four plate-glass shelves with brackets, grass mat, and swing.—Address, H. M., 26, Arlesford-road, Stockwell, S.W.

ROCHDALE AND DISTRICT PHOTOGRAPHIC AND ART EXHIBITION.—This Exhibition was opened on Thursday, January 21, and will remain open until January 30. The photographic section has been confined to members of the Society only, it being their first year; and, considering this, the collection [illegible] great credit on the numbers. Amongst the enlargements are some by Messrs. Mackenzie, Jones, Fletcher, Leach, and Blombey, which all show capital work. Messrs. Samuel and W. Ingham (the Secretaries) have a collection of prints in bromide and silver, embracing several subjects, prize cattle, old buildings, interiors, and snow scenes. Mr. I. P. Spedding has been successful in securing some pretty bits of Warwick. Mr. J. H. Hoyle is well to the front with some good landscapes in whole-plate. E. H. Aldridge has a selection of hand-camera pictures. Messrs. Threlfall, Blombey, and Fletcher have also an excellent display. Lantern exhibitions are given each evening from members' slides, Mr. Harry Fletcher having charge of the lantern, Messrs. Crabtree, Fletcher, Greenwood, Spedding, Ingham, and others having filled up the different nights.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

**** Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," *2, York-street, Covent Garden, London.*

ARS.—Received; with thanks.

L. MELDON.—Probably by combining three transparencies and photographing them.

C. E. WARDÉ.—Apply to Chance & Co., Birmingham. They may have such a glass in stock.

A. BROWN.—1. The second quantity is wrongly printed, as you suggest. 2. Yes. 3. Hypo.

"A."—The information desired, and much more on kindred subjects, will be found in the ALMANAC.

GRAINS.—You will find tables in the ALMANAC for facilitating the conversion of French into English weights.

ALEX. HENDERSON and WM. NOTMAN & SON (Montreal).—The address of Commandant Moëssard is 140, Rue de Grenelle, Paris.

C. H.—If the ground side of the glass faces inside, an occasional cleaning, as you suggest, is all that is necessary to remove the yellowness.

NEMO.—The *Court Circular* during the recent unhappy period invariably used the phrase "His late Royal Highness." From this we should be inclined to consider your description the correct one.

BRUNO.—1. The cut films of each of the makers you name are excellent. They do not require stripping. 2. Two or three ounces. 3. We have no means of telling; compare their respective sensitometer numbers.

LUX.—1. We are unable to give you exact weights, but for portability and lightness both types are unexcelled. 2. Without doubt. 3. A mere matter of taste. 4. Screw extension is, perhaps, to be preferred.

H. W.—1. The lenses referred to are all that lenses should be. 2. A quarter-plate portrait lens, and a half-plate, and 12 × 10 rapid doublet will answer your purpose. 3. Three grains each of potassium bromide and mercuric chloride. 4. Consult our advertising columns.

B. A. (Cambs).—If a process is published, it cannot be patented afterwards, either by the inventor or any one else. There is an exception to this, however, in the case of exhibitions, if certain conditions be fulfilled beforehand; but this would not apply in the case in question.

JOHN REDFORN.—1. Both the formulæ you specify are excellent for the various purposes named. 2. Metabisulphite of potash acts as a preservative of pyro or hydroquinone, and the same applies to soda sulphite and citric acid. 3. Leaper's *Materia Photographica*. 4. See answer to No. 2.

MRS. MOUNSEY.—The works we referred to are the flower photographs of Mrs. Payne and Mr. Stevens, to be occasionally seen in the Exhibitions. In our issues of May 20, 27, and June 17, of 1888, you will find a series of articles on photographing flowers. Our publishers will supply you with the numbers.

E. F. asks: "Could you kindly inform me in the JOURNAL what is used by crayon manufacturers to bind the black powder together in the making of black crayons?"—Different manufacturers use different materials, such as wax, soap, tallow, spermaceti, &c., or mixtures thereof. Of course they do not publish the formulæ they use. A few experiments will soon prove what will suit your purpose best.

WARWICK.—If your son was articled for five years to learn the business of a portrait photographer, he is certainly not being properly taught if he has been kept for three years and a half at the suburban printing place, doing an ordinary printer's duties, and has not yet had an insight into studio work and the management of sitters. Do as you suggest; act on the advice of your solicitor. We fear your case is not an isolated one with those who take "articled pupils" with a good premium. Scott's case was reported in the daily papers a few months back; we cannot give you the date.

WOODPECKER writes: "1. I should be greatly obliged to you if you let me know if, after selling a photograph for three years of a church, I can register it to prevent any one copying it. I might say a weekly paper has a large illustration from one of my photographs, and, after writing for the photographer's name, did not mention it. 2. Do you undertake to register photographs?"—1. The photograph can be registered at any time. It was very unhandsome of the paper not to credit the artist with the photograph from which the illustration was taken; but this is quite a common practice with illustrated papers. 2. Our publishers undertake the registration of photographs.

A. ROWELL.—If the negative has been varnished, it can still be intensified, but it will be necessary to first remove the varnish. Supposing that it is a spirit varnish, as most photographic varnishes are, this may be easily done. Place the negative in a dish of strong methylated spirit, and cover it up. Allow it to soak for an hour or two, with frequent agitation, and an occasional rubbing with a pledget of cotton wool. Then change the spirit for fresh, and repeat the treatment, and finally rinse with clean spirit. Some varnishes are very refractory; in this case the spirit should be used warm. No attempt should be made to intensify the negative until the whole of the varnish has been entirely removed, and the negative well washed with water, otherwise stains will result.

COPYRIGHT writes: "I have purchased a business which contains some very valuable negatives; these were copyrighted some ten years ago by a previous proprietor, now dead. I would be much obliged if you would answer, through your "Answers to Correspondents" column, whether these negatives could, or should, be re-copyrighted in my own name, and how I should proceed."—As the copyright in a photograph is vested in the author of the work, our correspondent could not re-register it in his name. The only way we can see of securing copyright in the negatives is to get it assigned by the representatives of the deceased author—the one who took them.

C. J. KIRK writes as follows: "Some time ago, in reply to a querist, asking the reason for stains appearing on opalines, you said the gelatine is mostly acid. I find also that glue, with which we stick on the backs, is even more so. Can you suggest a sure and practical way of neutralising these? With the greatest care and cleanliness we find these spots sometimes appear after even six months. Your help will be greatly esteemed."—As our correspondent says, glues are, as a rule, more acid than gelatines, and therefore should always be avoided. Instead of attempting to neutralise the acid in gelatines, it is far better to use those which are neutral. English gelatines, such as those of Nelson & Son, are in this condition, and therefore should always be used, in preference to foreign, for mounting photographs.

J. D., who is a second operator in a London studio, writes that he attends to the camera in every detail with the exception of uncapping the lens and the posing of the sitters (some require no posing), which part the first operator does. At the finish of the day's work the second operator develops the whole of the negatives, the first operator not seeing them till they are finished next day. The question is, the first operator says he took them, when the second operator says he also took them. Is the second operator equally justified in saying he took them, the first operator posing the sittera and uncapping the lens, whereas the second operator does the focussing, seeing that there is nothing out of place, bad points, &c., and last, but nowise least, develops the negatives?—The second operator is assistant to the first. He can only claim as such. He is clearly entitled to the credit for the exposure and development—the manipulating part of the work.

CROYDON CAMERA CLUB.—Fixtures for February.—1, Annual Meeting, election of officers, &c. 15, *Warm Tones on Bromide Paper*, by J. Weir Brown. 29, Lantern Night.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—On February 2, Professor R. Meldola, F.R.S., will deliver a lecture on *Photography as a Branch of Technology*. Tickets can be obtained on application to the Assistant Secretary.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—February 4, *Means of Obtaining Clouds in Landscape Negatives*. February 11, *Isochromatic Plates*, Mr. John Howson. February 18, Lantern and Musical Evening, in the Large Hall, Champion Hotel.

THE PHOTOGRAPHIC CLUB.—February 3, Ordinary Meeting, the paper *On Photo-mierography* being unavoidably postponed, owing to the indisposition of Mr. T. Charters White. February 10, *Glass Blowing for the Laboratory*, Mr. A. Haddon.

PHOTOGRAPHY IN COURT.—*Turner* v. *Elliott*.—The plaintiff in this case is Mr. J. E. Turner, the owner of two freehold houses called Brooklands and Covington-house, both in Park-road, Barnet. The defendant, Mr. J. J. Elliott, is the owner of land (adjoining the plaintiff's premises), on which are works of considerable extent, and in connexion with the defendant's business of a photographer or photographic printer, and from which, according to the plaintiff's statement, he permitted to escape vapours, gases, smoke, and offensive smells, injurious to the health and comfort of, and occasioning nuisance and injury to, the occupiers of the plaintiff's premises. The plaintiff accordingly came to the Court for relief in the shape of an injunction to restrain the defendant, his servants, workmen, and agents, from permitting any vapours, gases, smoke, or offensive smells to escape from the buildings or works of the defendant, or otherwise carrying on his works in such a manner as to be injurious to the health or comfort of, or occasion nuisance or injury to, the plaintiff, or his family, or other the occupiers of his premises. The action came on for trial in May, 1891, and, after the trial had lasted several days, his Lordship, by consent, appointed Professor Raphael Meldola, F.R.S., to visit and inspect the premises, and to inquire and report whether or not the plaintiff's premises were affected by smells or smoke coming from the defendant's premises; and, if so, in what manner and to what extent, and how the same were caused or arose. Professor Meldola's report was brought before his Lordship to-day. Mr. Justice Romer found on the evidence that no nuisance arose from the defendant's chimney, but that there was a nuisance from the albumenising process carried on at the defendant's works. His Lordship accordingly granted an injunction to restrain the defendant from permitting any vapour or offensive smell escaping from his works so as to be a nuisance to the plaintiff in respect of his premises. As, however, the plaintiff had not been successful in proving the whole of the allegations made by him, his Lordship ordered the defendant to pay only half of the plaintiff's costs, and directed that Professor Meldola's fee should be borne by the parties in equal shares. The operation of the injunction was suspended for a month.

CELLULOID FILMS.

From such indications as we are able to observe, we believe that the employment of cut celluloid films in place of glass plates for the support of the sensitive film is likely, during the approaching season, to be more extensive than in preceding years. Film carriers for placing in the ordinary dark slides are to be obtained, fulfilling the important requirements of simplicity, efficiency, and inexpensiveness, while to a great many hand cameras special sheaths are now fitted which allow of films being held *in situ* as easily as glass plates. Thus, so far at least as the amateur worker is concerned, there are abundant facilities for the adoption of films in outdoor work to effect that considerable saving of weight which has so long been his aspiration.

Hitherto the use of cut films for out-door photography has not prevailed to anything like the extent that had been predicted or expected of them on their first introduction. The causes of this comparative neglect are perhaps threefold. In the first place, few, if any, efficient means of holding the films in the ordinary dark slide in a perfectly plane position were, until recently, available; secondly, such commercial brands of films as were on the market were only too frequently open to the imputation of being defective, both as regards the flatness of the films themselves and the irregularity and inferiority of the emulsion with which they were coated; and, thirdly, their development and general manipulation were erroneously, if, perhaps, not quite unnaturally, assumed, and sometimes found to be more uncertain and troublesome than glass plates. The first of these drawbacks no longer exists; the second, owing to improved methods of manufacture and greater knowledge on the part of the manufacturers as to the conditions of successful preparation and coating of the films, has also, we believe, in great measure disappeared, and the third is also equally non-existent.

It is a condition inseparable from all new methods and processes that in the earlier stages of their employment, failures and irregularities should be experienced, and to the manufacture of cut films coated with gelatine emulsion, and consequently to their use and manipulation, this reservation applies with peculiar force. It was hardly to be expected that the makers would at once be able to determine the best kind of celluloid for coating purposes, the particular preparation or cleaning that the uncoated film should undergo, and the best system of applying the emulsion to the support. Experience alone could give the necessary knowledge, which is the key to success in these regards. That this knowledge has been attained by the various manufacturers, native and foreign, we are inclined to believe, inasmuch as for some time past the complaints of badly coated films and "spotty" emulsions, which we at one time constantly received, have almost entirely ceased.

These remarks are suggested by the brief paper on celluloid films read by Mr. J. D. England at a recent meeting of the West London Photographic Society, and which our readers will find reproduced at p. 87 of the present number of the Journal. Mr. England, we believe, has for some time past been engaged in the commercial preparation and coating of celluloid films, a fact which lends additional interest to his remarks. We cannot reasonably expect the modern manufacturer to admit us to the secrets of his business, and therefore we do not complain that in his excellent little paper—the brevity of which is not its least merit—Mr. England does not tell us the preparation which he gives the uncoated sheets of celluloid before applying the emulsion, and neglects to describe the "special appliances" used in coating to which he refers. All the same, this information would have been interesting, we are sure, both to his hearers and readers.

The advantages of celluloid films over glass plates are obvious. Their lightness, portability, and immunity from breakage are of the highest economical value. They reduce, if they do not prevent, halation when photographing many subjects, such as those where the tops of trees cut the sky-line; although, for interiors, a backing of some kind cannot by any means be neglected. By using carriers specially made for cut films their exposure in the ordinary dark slide becomes a matter of ease. We are inclined to hope, however, that in course of time the dark slide itself may be so adapted as to receive either glass plates or cut films at will, without the necessity of having to use special carriers. This may be a suggestion worthy the attention of the makers.

We may pass by the exposure and development of celluloid films, since these operations differ in no material respect from glass plates. The films keep flat in the solutions, and there are varnishes procurable which, when applied to the film, do not disintegrate the support, upon which, as is well known, solutions containing alcohol have a solvent action. The applications to which celluloid films may be put are, as Mr. England points out, both diverse and numerous. For stereoscopic purposes, the fact that a stereoscopic film negative can be cut with a pair of scissors, and the halves transposed and mounted upon glass, thus obviating the necessity of reversing the prints, it is obvious that the employment of celluloid films is of great value at a time which is witnessing a marked revival in this branch of photographic work.

Film negatives are useful in obtaining reversed results for photo-mechanical work; and this fact, to our thinking, is one which will not improbably lead to a considerable use of cut celluloid films among professional photographers, who, up to the present time, have, we believe, neglected them almost entirely. That they will ever supplant glass plates for studio work is hardly feasible, but we are surprised that professional landscapists have not adopted them. When, however, a de-

lusion, which we know to be prevalent, that the sensitive emulsion placed on sheets of celluloid necessarily falls short in point of quality from the sensitive compound on a glass plate, is removed, we fully expect that professional outdoor photographers will adopt films instead of glass—at least, where a great number of plates have to be carried about from place to place. Mr. England's warning against packing films under too much pressure, and so avoiding any loss of sensitiveness thereby caused, is a hint which should be borne in mind by amateurs, who may be prone to pack these films too closely together and under too great pressure.

COLOURED PHOTOGRAPHS.

A VERY important part of the business of the professional photographer in many towns is the supplying of coloured photographs, often the only class of work which his clients will accept when, the portrait of some dear one gone to his long home, a portrait is often as not most indifferent in execution. There at once arise two questions, first, the probability of retaining the likeness when the painting is fully done; and, second, the probability of the permanence of the picture when it is done in colours. These two initial difficulties are potent stumbling-blocks, and, more frequently than not, every endeavour is made to induce the client to have a picture in black and white; for here there are processes to choose from whose results may in all human probability be classed as absolutely permanent—platinotype and autotype, and, as considered by some, though there is an element of doubt, bromide prints. These, if worked upon by suitably selected colours, leave no doubt whatever upon the photographer's mind, and he feels certain that, if his is a "family business," there will be no pictures brought to him in the course of a dozen years showing fading effects of a marked and unreliable character. When colour effects are, after all, selected, there can be no doubt that experience points out that a large number do fade, and an anxious point to consider is how to proceed to prevent such disaster.

Now, there are, to begin with, many mediums upon which the picture may be executed—paper, opal, ivory, and paper prepared with gelatine for carbon work.

When opal is selected, there has, in time gone by, been a great predilection in favour of collodion transparencies, and, in view of the non-fading character of the old glass positives, it has been assumed that opal transparencies in collodion should also keep from fading. There is no excuse for a photographer getting a large price for a painted photograph, the base of which he knows to be fugitive; and it must be observed that the parallel mentioned is false. Old glass pictures that have not faded are protected by a thick coat of varnish. Where this has not been done the picture always fades, that is, alters, and darkens, through the action of the sulphur in the atmosphere upon the silver of the image. A strong varnish upon an opal to be painted, as are most, in water colours, is not permissible, from the technical difficulties it would put in the way of the artist-painter. Hence such a base should decidedly not be chosen for the purpose. But a silver in gelatine, *i.e.*, a bromide print, is far more analogous to a glass positive, owing to the silver being imbedded in a film of gelatine practically impermeable to air. Further, the removal of hypo is more readily carried out than when the bromide is on paper, and, so far, is safer. Hence about such a base it can be said there is only a question as to the possibility of fading. Carbon prints upon opal may be looked upon as absolutely permanent the only possibility to the contrary being the liability of the film to slide off when large quantities of medium or of gum are used in the shadows to give effect and richness. To mention this is to point out a remedy.

As to a paper basis, there were the three typical methods we have named—carbon, platinotype, and bromide—each having its advocates. As to the permanency of the latter, our remarks just made about opal are all that need be said. Platinotype is so familiar that it can be carried out on the premises, while, for some reason or other, carbon work cannot be—or, rather, we should say, is not usually—so done, the services of the professional enlarger generally being called in. It is a pity that this should be so, seeing the process is far easier than those who have not tried it can believe. To paint upon the surface of a carbon print requires some little thought at first, for the colours do not "wash" so freely as on drawing-paper, or, indeed, as platinotype, though it must be observed that the latter need some kind of sizing first, to get rid of the porosity of surface induced by the hot fluids they are developed in, if from no other cause. Carbon prints, again—whether on paper or opal, and especially on the latter—have the advantage of allowing any objectionable shadow or unwelcome form to be removed by the scraper or ink-eraser, which is impossible with platinotype, through the image being imbedded in its texture.

So far for the actual photograph itself upon which the artistic colour work is carried out. There remains to consider the colours themselves, a question of great, nay, paramount importance. The *technique* of the artist is no province of this paper to deal with, but the actual colours used are decidedly within its purview, and we purpose shortly to refer to them in a further article from a chemical and technical standpoint.

GRADUATED VIGNETTES.

OUR condemnation of the ordinary "vignette glass" in our article of a fortnight ago has been taken too seriously by more than one correspondent, as applying to every form of graduated vignette, unless used in conjunction with a rotating frame or other means of further softening the gradation. If reference be made back to our remarks, we think it will be clearly seen that they referred solely to the hand-made vignette glasses in which the delicacy of the shading depended entirely upon the judgment and skill of the workmen in removing more or less of the flashed colouring matter from the surface of the plate, and in which, under the circumstances, the result was never, and could scarcely be expected to be, of a satisfactory character.

While in a great measure adhering to the opinion already expressed that the best results are only to be obtained when the printing frame is kept in constant motion, we are ready to admit that, with a properly and carefully graded vignette, the necessity for this constant alteration of position of the frame disappears. But such perfectly prepared masks are rarely, if ever, met with in commerce, and few photographers deem it worth while to give special attention to their manufacture, hence the numerous makeshifts of former years continue to be used.

In point of convenience nothing can possibly excel the graduated screen placed in contact with the negative, as it were, forming part thereof and effecting, without other assistance, the whole task of graduation. With such appliances the printing frames may be left to themselves, instead of being closely and

constantly watched, as when other methods of graduation are adopted, and the process of vignetting becomes as easy as ordinary printing. But to secure this result the vignetter must be not only perfect in itself as regards shading, but must be suited to the character of the negative with which it is to be employed.

. There are numerous methods by which vignetting masks, perfect in their graduation, can be prepared with very little trouble if the photographer will but give his attention to the matter; and, though most of these have been previously described, it may not be out of place to recapitulate them here for the benefit of those who are not familiar with the various methods. The process may be divided into two parts, the mechanical and the photographic, the former having to to do with the graduation of the screen, the latter with the sensitive surface employed.

Taking the mechanical side of the question first, we have choice of methods. The camera may be employed, if desired, to produce a vignetted *cliché* or positive, from which negatives may be reproduced by contact printing, or, if only a single one be required for a special negative, it may be made direct. The *modus operandi* in this case is very similar to that of vignetting an enlargement; an aperture or disc, according to whether a positive or negative is required, is kept in motion between the lens and the source of light, or between lens and plate, and at such a distance as to be completely out of focus, the degree of graduation depending upon the amount of movement imparted to the mask or disc. It is obvious that, when one accurate graduation is obtained, it may be reproduced to any extent either of the same dimensions or larger or smaller. The employment of the camera, of course, necessitates the use of tolerably rapid plates or films.

The simpler plan, however, seems to be to produce the *cliché* in the printing frame by one or other of the methods usually adopted for direct vignetting, but necessarily by one of those of which we have spoken as giving perfect graduation. Some operators may prefer to use their favourite vignetting method, but none, we think, will be found to give results equalling those obtained from the revolving frame. This is, moreover, so easily put into practice that we strongly recommend it in preference to any other, no matter whether artificial light or daylight be used, though the precise methods of working will differ slightly with the light.

A square board of suitable size is suspended by its corners, so as to form a horizontal table, and this is hung from the hook of an ordinary roasting-jack as the source of motion; or, if the jack be not available, a number of strands—the more the better—of worsted twisted together will form a very good substitute, untwisting and re-twisting a number of times under the weight of the printing frame and its platform, and only requiring an extra wind occasionally to prevent its becoming stationary.

Working in ordinary diffused daylight with one of the slower photographic processes, the printing frame is placed upon its revolving platform, and left until the light has sufficiently acted. If a reversed *cliché*, from which negative vignettes can be reproduced, is required, the front of the printing frame is covered with an opaque mask, carrying an aperture of suitable shape, the size of which will depend in a great measure upon the distance at which it is placed from the sensitive surface; the greater the distance, the wider the spread and softer the gradation. If the light be bright, the aperture is better covered with tissue paper or ground glass, though, even in direct sunlight, if the rotary motion be kept up regularly, it is scarcely possible to produce a really bad result without this extra means of diffusing the light.

It is quite unnecessary to resort to any of the usual methods of softening the edge of the aperture by serrating or by gumming cotton-wool to it. The revolution of the frame produces the softening, and the only effect of serrating the aperture is to practically increase its size. Of course, any shape of aperture may be adopted, from a true ellipse to any of the forms more closely assimilating to the outlines of the head and shoulders, one of the best, perhaps, for general purposes being an egg shape, with the smaller end uppermost. In most vignetted busts it will be found that the shading of the lower portion of the body is more gradual than that about the head, which should be clearly cut against a nearly white background. To secure this effect in the vignetter, it is only necessary to incline the mask at an angle with the sensitive surface, the upper portion being the nearest.

If it is desired to produce a negative vignetter direct without the trouble of a second operation, instead of the mask with an aperture, it will be necessary to use a glass plate with a piece of opaque paper or card of suitable shape fixed to the centre. For instance, if it be necessary to form a screen to vignette closely to the shape of a particular figure, we should cut out a piece of opaque paper the shape of the figure, but an eighth or a quarter of an inch larger each way, according to the degree of softness required and the distance at which the mask was to be placed from the sensitive surface. This would be arranged so that the clear aperture left in the centre of the vignetter after exposure would be the size of, or a trifle less than, the actual size of the figure to be operated on.

In daylight, and with slow photographic methods, the exposure will, of course, be a comparatively long one, and the progress of the operation can be watched as in ordinary printing, and slight modifications of the adjustment of the mask made if deemed necessary; but, where artificial light is concerned and rapid plates, some little extra care will be required in order to ensure the proper diffusion of the light, and the size, shape, and distance of the mask will have to be accurately adjusted in the first instance, as there is no opportunity of subsequently altering them. The mechanical arrangement of the revolving table will remain the same as for daylight, and the chief care will have to be in the arrangement of the position of the light. This will vary with the source and character of the light and its strength, the more powerful it is the greater the distance at which it should be placed in order to avoid too sudden contrast. The softness of gradation can be greatly modified, too, by changing the angular position of the light; if vertical, or nearly so, in relation to the exposed surface, the gradation will be comparatively abrupt, and, in proportion as it is brought down to an angle of about forty-five degrees, the softening will be correspondingly increased. It should also be remembered that a large area of illuminating surface will give a softer result than a small flame or point of light, and that therefore means should be adopted to increase the illuminating area by means of reflectors, or by multiplication of the number of lights. A large plane reflector in close proximity to the light will produce the desired effect.

Of the sources of light available we should select for gelatine or rapid plates gas or lamplight suitably diffused. For slower plates, such as collodion emulsion, the more powerful form of lamplight, with comparatively long exposure, will prove suitable, or magnesium wire, burnt at a distance from the sensitive

surface, and close to a light-coloured wall or reflector. Whatever the source of light and other conditions, it will be advisable to ascertain by actual experiment beforehand the most suitable positions for the light and sensitive surface.

The photographic methods of producing the vignetters will be discussed in a succeeding article.

The New Methylated Spirit.—The question we asked some time ago, as to what the photographic societies were going to do in the matter of attempting to obtain some modification of the obnoxious regulation necessitating the addition of mineral naphtha to methylated spirit, has, we are pleased to observe, been answered in two quarters. The Great Britain Society had the matter under discussion at its last technical meeting, and the London and Provincial immediately afterwards followed suit. We hope to hear that concerted action will soon be taken to approach the Somerset House authorities, with the view of obtaining a remission of their Draconic rule.

The Camera Club.—The list of members of the Camera Club now totals up 684, the town members numbering 322, 18 being life members. There are 269 country members, of whom 43 are life members. The foreign members number 39, and 54 members joined from the late Amateur Mechanical Society, of which 12 are life members. We are glad to learn that with the present membership and the prospective normal increase for the current year the Club is on a sound footing. Certainly a roll of 684 is one of which the Club may well be proud, and the best possible justification of its foundation and existence.

Professor Meldola's Lecture.—Although the attendance at Professor Meldola's lecture on *Photography as a Branch of Technology*, at the Photographic Society of Great Britain, on Tuesday night, was not large, the reception of the lecture was as favourable as could be wished for, and the discussion that ensued eminently appreciative and practical. Both as a review of the important part photography plays in modern science, as well as suggestive of the possibilities which underlie such an institute as the Professor pleads for, the lecture was a valuable utterance, and we are confident that the Society and the affiliation scheme will profit by the thoughtful manner in which the Professor performed his task. Unhappily, he was unable to be present to hear the cordial manner in which his ideas were echoed.

Papers at Societies.—Any one who turns up the reports of photographic societies, say, of twenty years ago, must necessarily be struck with the marked difference between the proceedings at them then and now. Then the papers read were almost exclusively of a technical character—new processes, or modifications of old ones; now they partake largely of an entertaining nature, a prominent feature being the lantern; indeed, in some instances just now, lantern society would be a more correct title than photographic society. Much of this change is due to gelatine quite superseding all the other dry-plate processes.

Patents.—The number of patents taken in connexion with photography increases annually, and some will, no doubt, lead to litigation. There is no question that the litigation of patents is usually made more costly than need be. Recently, Mr. Justice Romer, in giving judgment in an action for infringement—with regard to screws—that had occupied the Court for fourteen days, and in which most of the leading counsel in patent matters were engaged, took occasion to severely censure the method of conducting patent cases generally. He complained loudly of the time occupied and the expenses incurred in these actions, and said the fault lay with the professional gentlemen engaged—over-zeal, want of compression in examination, cross-examination, &c. It is to be hoped that his Lordship's remarks will have weight in any case in which photography is involved.

Stage Moons.—Professor Hubert Herkomer is a man of many parts. He has just been telling theatrical managers how to light their stages—both with gas and moon. Mr. A. W. Pinero thinks the Professor may certainly claim to have discovered a new moon, of which, however, no particulars are vouchsafed. Mr. Pinero has known many stage moons, of which the most inoffensive is that for which we are indebted to the ordinary magic-lantern. At Bushey this illuminates the fleeting clouds. The lantern is an old servant of the stage.

Instantaneous Photographs.—On several previous occasions, we have directed attention to the fact that "instantaneous" pictures frequently do not convey the impression intended. Instead of giving an idea of moving objects, they often give one rather of sudden suspended motion. Thus a photograph of a railway train, however fast it might be travelling, if it showed the spokes of the wheels sharply defined, would represent it as standing perfectly still. The late Mr. O. G. Rejlander, many years ago, well exemplified this in a couple of photographs of a girl at a spinning-wheel. In one, the foot and spokes of the wheel were sharply rendered; in the other, where several seconds of exposure had been given, they were, of course, considerably blurred. Yet it was the latter that gave the best impression of an instantaneous picture. This subject was ably treated by Mr. Maskell, at the Camera Club last week.

Jena Glass.—Is not Mr. Thomas S. Taylor, of the firm of Taylor, Taylor, & Hobson, who the other day gave a discourse on lenses before the members of the Liverpool Amateur Photographic Society (see p. 92), incorrectly reported in being made to say that he could see no advantage in employing the new Jena glass in photographic objectives, except "variety"—whatever that may mean? Surely Mr. Taylor must be aware that the properties of high refraction and low dispersion, which certain of the new glasses possess in an eminent degree, conduce, among other things, to obtain a degree of flatness of field which, as was said by Mr. Debenham at the London and Provincial meeting the other night, constitutes the greatest advance in photographic optics since the introduction of the Steinheil aplanat twenty-four years ago. Will Mr. Taylor kindly inform us with what other kind of glass than that of Jena it would be possible to construct, for example, a lens having concentric external curves—that is, curves struck from a common centre—by which a corrected image would be formed? We incline to the opinion, however, that Mr. Taylor has not been rightly reported.

Fetid Albumen Paper.—A case of considerable interest to photographers who sensitise their own paper was decided in the Court of Chancery one day last week, a brief report of which appears in our previous issue. It was an action to restrain Mr. Elliott, of Barnet, from carrying on his business in such a way as to cause a nuisance to the plaintiff, a neighbour. The suit, it may be mentioned, by reason of the conflicting evidence adduced, occupied the Court for several days last year, when the learned Judge appointed an expert to visit the premises and report. The report was to the effect that, although there was no nuisance in regard to the chimney complained of, there was from the albumenised paper employed. Hence an injunction was granted in respect to that. If the effluvium—"albumenous vapours," as one of the papers has it—given off in sensitising some papers is a legal nuisance to neighbouring houses, what must it be in the same building? Many photographers who do their printing on the same premises as they have their studio do not occupy the whole of the house. Now, after the decision just referred to, any of the other occupants could easily, if they choose, put the photographer to serious inconvenience. We were forcibly reminded of this the other day on entering premises, the lower portion of which was let as offices, and the upper occupied by a photographer. The effluvium from sensitising paper pervaded the whole building at the time of our visit, and was most sickening.

Important Copyright Decision.—An action, under the Copyright Act, was decided in the Court of Queen's Bench on Friday

last week, which is of considerable importance, inasmuch as some novel points were raised. Messrs. Lucas, Mendoza, and the Berlin Photographic Company brought an action against Messrs. Williams & Sons, of Wimbledon, for selling photographic reproductions of their copyright in pictures such as *The Peacemaker*, *Quiet to Ride and Drive*, &c. The plaintiffs, instead of taking summary proceedings, elected to sue, in a superior Court, for damages, and an injunction to restrain—penalties under Section 6, and damages under Section 11. One of the pleadings of the defendants was that, in the case of Mr. Lucas, the plaintiff sent his agent, who gave an address at Belfast, to sell him copies, and after the sale a writ was issued. One of the defendants in his evidence said that, when he purchased the photographs, he thought he was justified in doing so, and afterwards, when he met the man who sold them, he chastised him, "giving him black eyes and a cut head." One of the points raised by the defendants' counsel was, that the Act complained of being a criminal one, in order to recover, the plaintiffs must prove that the defendants committed the acts knowingly, and there was no evidence of any such acts. Mr. Justice Collins also pointed out that under Section 11 the damages must be special, and of this the plaintiffs had given no evidence at all. In the result, the jury found that the defendants had sold the pictures without guilty knowledge, and for the plaintiffs with a farthing damages in each case for exhibiting, and no damages at all for the sale, as that was to the plaintiffs' own agent, and at their own instigation. An injunction was granted to restrain further sale, and all copies in hand to be forfeited, and the defendants to pay the costs. On the application of the defendants' counsel execution was stayed, so that we have possibly not yet heard the last of the case.

Compromising Copyright Cases.—In the foregoing case the defendant in his evidence said that after receiving a letter from the solicitor, he went to his office and saw him, and was very indignant at the proposal made to him as to a settlement, and left the office abruptly. In prosecutions for infringement of copyright, the owner of it has two courses of procedure open to him. One summarily before a magistrate, the other by action in a superior Court. The latter is the more costly mode of proceeding, and not infrequently induces the defendant to pay a certain sum to compromise the matter. It was mentioned that the photographs complained of were made in Germany, and we have seen similar ones hawked about the streets of London. This being the case, how is it they are allowed to pass the Customs? Section 10 of the Act expressly forbids the importation of pirated works. One would almost have thought that the owners of valuable copyrights would prefer to prevent the importation of piracies rather than organize costly prosecutions against persons who might be innocent of knowingly transgressing the law.

PHOTOGRAPHING "THUNDERBOLTS."

"What is a thunderbolt?" is a reasonable question to ask, now that photographing wild fowl of that ilk has begun. Along some parts of the south coast of England nodular lumps of a heavy substance are to be found, which some of the peasantry gravely point out to the visitor as thunderbolts. Somewhat crystalline masses of the same substance are found in the chalk and clay dug out in the Channel Tunnel works, and so bright as to strongly resemble gold; in time the exterior oxidises, and each lump assumes the ordinary appearance of iron pyrites. These fetishes, like the nodules of hematite iron pointed out as thunderbolts near Tenby, were never launched from heaven by Jove; indeed, Jupiter, from his ivory throne with his screaming eagle at his feet, would have been ashamed to hurl such sorry specimens of his power, as any one would say did he see the Channel Tunnel specimens lying before me as I write. They came from the works on the English side of the Channel. When examining the works on the French side, I heard nothing about the finding of pyrites.

It was at the meeting of the Camera Club recently that Mr. A. Maskell projected on the screen a lantern picture of a "thunderbolt," taken, he said, by an amateur at Newcastle (Mr. Dunn) during a storm of thunder and lightning. When the flash took place it differed in appearance from no other flash; but, upon developing the plate, a remarkable object was revealed—a kind of luminous globe, with flame-like projections here and there from its outer edge. On the background were spots and markings, some of which may, or may not, have been defects in the plate. In the discussion, I asked Mr. Maskell if this photograph were well authenticated, because, if genuine, it was unique in the histories of photography and meteorology; he then gave as his authority a number of a periodical, which he laid upon the table.

This photograph will soon draw criticism in wider fields than that in which it first became known, because there is none to compare therewith. The scientific world must guard itself against hoaxes performed, say, by "larky" young men—such as those who find pleasure in tying together the tails of farmers' cows—and, at the same time, ought, by experience, now to have wisdom enough not to howl down novelties brought before it in all candour by truthful persons. Scientific men at first scouted the first news of the existence of flying fish; the Royal Society itself rejected Franklin's first paper on lightning conductors; mesmerism was tabooed by orthodox science for a generation, and now is accepted by it in a cowardly way by forging for it the new name of hypnotism. A broader spirit of toleration is now abroad, for, the wiser men are, the more are they aware of their own ignorance: the ignorant and the brutal, on the contrary, are conscious that they know everything. On these grounds, probably, in scientific circles judgment will be suspended about Mr. Dunn's photograph, and time claimed for the reception of abundant corroboration from other sources, even should Mr. Dunn's acquaintances testify that he is not a notorious practical joker. In London one is at a disadvantage in knowing nothing of the source of information, for Mr. Dunn may perhaps be noted for the gravity of his demeanour and the trustworthiness of his utterances.

One thing, until explained away, appears to tell strongly against the picture being a photograph of globular lightning. The lens was uncapped, as usual when taking photographs of forked lightning by night, and after the flash Mr. Dunn put on the cap; thus no shutter was used, for shutters are useless in photographing forked lightning. Under these circumstances how is it the fire-ball comes out sharp all over and near the middle of the plate, instead of making a band across the plate by its travelling motion? Information has reached me that a copy of the photograph has reached the Royal Meteorological Society, and that additional specific particulars have been asked, but not yet received.

Until recently, it was an unpleasant thing to be a witness to an abnormal phenomenon which cannot be seen or repeated at will. When they asked the captain to come on deck and to look, with all the rest of the living souls on board, at the sea-serpent wriggling after the ship, that captain groaned, buried his head in the sofa cushions, and replied that he would die first. Did they not know that Captains Smith, Brown, and Robinson had testified to having seen the sea-serpent, and been thenceforth regarded by their employers and by their passengers as scarcely worth their salt?

Come we now to what is really known in relation to what the proletariat call thunderbolts. "Globe-lightning" or "fire-balls" present perplexing phenomena to electricians; but that globular lightning is a fact is not denied. The fire-ball is much less brilliant than forked lightning; indeed, it is rarely brighter than red-hot iron. Sometimes the ball is visible for several seconds; it is always spherical, and seldom more than a foot in diameter; it appears to fall from a thunder-cloud by its own gravity, sometimes rebounding after touching the ground. The fire-ball usually bursts with a bright flash and loud explosion, occasionally discharging flashes of lightning. No experimenter has yet succeeded in producing artificially anything resembling these natural and intensely charged Leyden jars. The term "thunderbolt" is nowadays rarely used except by poets and penny-a-liners. Such are the statements of Professor P. G. Tait about globular lightning.

W. H. Harrison.

AMERICAN NOTES AND NEWS.

Flowers by Gaslight.—The Cuban cactus is a species of the night blooming plant which, we are informed, only blooms at midnight. The *St. Louis and Canadian Photographer* has a photo-engraving of a group of these flowers, the negative of which was taken by a photographer in his gallery at midnight, with an exposure of about four and a half minutes to gaslight.

The "Dominion Illustrated."—We are sorry to hear of the stoppage of the *Dominion Illustrated*, a Canadian weekly of a high-class character, which depended very largely upon photography for its illustrations. The paper, it is said, will in future appear as a monthly. It is to be regretted that the measure of support accorded

to our contemporary should have led to this step. Can it be that the fidelity of the illustrations was not appreciated?

Aluminium Flashlight.—Dr. Piffard writes to *Anthony's Bulletin* in reference to the proposed substitution of aluminium for magnesium in flashlight photography, stating that he exhibited pictures made by aluminium flashlight at a meeting of the Society of Amateur Photographers of New York three or four years ago. He says that properly prepared aluminium is, for certain purposes, to be preferred to magnesium. It gives a quicker flash, but is very costly.

Photographing a Furnace.—Messrs. Meachim & Sabine, of Youngstown, Ohio, recently accomplished an interesting piece of work in photographing the bottom and interior of a Gerard furnace, the stack of which was seventy-five feet high, and the interior, of course, perfectly dark. An exposure of half an hour was given, with the camera upside down, and a successful negative resulted. We are not told what luminant supplied the actinism necessary for securing "perfectly dark interiors."

"An Appropriate Response."—The Columbus Camera Club held its annual meeting a little while ago, and, according to the report, it brought out the largest gathering the Club had had for three months. "Many faces of irregular attendants were present," we read. Only the faces? The Bausch and Lombe Lens and Shutter, won in a competition, was presented to the victor. This gentleman, Mr. H. Irvine, "responded appropriately, and *passed round the cigars.*" The appropriateness of the response was so highly appreciated by the members present that they subsequently elected Mr. Irvine a vice-president of the Club.

Death of Willard H. Fuller.—We are sorry to hear of the death of Mr. Willard H. Fuller, of the Scovill & Adams Co., New York, after a brief illness, at the age of thirty-seven. Mr. Fuller was long connected with the Scovill Manufacturing Co., and was much respected. The funeral was attended by, among others, Messrs. W. Irving Adams, and H. Littlejohn (Scovill & Co.), W. I. Lincoln Adams (*Photographic Times*), H. C. Price, H. Flammeng, Dr. Charles Ehrmann, and representatives of Messrs. E. and H. T. Anthony & Co., the Eagle Plate Company, and the Board of Trade and Transportation of New York. He leaves a widow and two young daughters.

"St. Blaise" Photographed.—The *Photographic Times* recently presented its readers with a capital photogravure of St. Blaise, the $100,000 stallion. The colour of the picture is said to suggest the colour of the horse, so that it is as satisfactory a representation as could possibly be obtained by photographic means. The breeder of the horse is said to have been "Lord Arlington." It was Lord Alington—without inverted commas. To say, as our contemporary does, that the animal won the English Derby as a three-year-old is in the nature of a redundancy, since, as everybody knows, only three-year-olds are allowed to compete in that classic contest. Then—but stay, this is not a sporting journal.

Rare Earths.—Mr. Waldron Shapleigh recently exhibited at the chemical section of the Franklin Institute a number of specimens of the salts of the rare earths, many of which, it is safe to say, are only known to the majority of chemists on paper, that is, in the text-books of chemistry. Of a few of these, however, such as zirconium, lanthanum, and cerium, it is claimed that they should no longer be classed as rare earths, as hundreds of tons of ores from which they are obtained are found in North Carolina; they also exist in Brazil. These, and similar bodies—of which, we believe, incandescent mantles are made—can, it is said, be supplied from the localities named in proportion to the demand created by the arts and manufactures.

Judging Lantern Slides.—A little while ago the Executive Committee of the American Lantern-slide Interchange met, and examined and tested the slides of fifteen clubs, aggregating very nearly 1400 slides! Fourteen hundred slides at a sitting! Phew! The self-doomed martyrs—we mean Committee—consisted of Messrs. F. C. Beach and W. H. Rau and Dr. G. H. Bartlett. It seems that on a previous occasion some of the clubs wished to know in detail why their slides were rejected. A code of reasons has, therefore, been adopted, by which the quality of a slide may be readily determined. Each rejected slide will be marked with a letter, which will indicate the following defects: (A) Too weak, flat, or over-exposed; (B) too dense, chalky, or under-exposed; (C) out of focus; (D) badly matted, aperture too large, or incorrectly labelled; (E) uninteresting subject. It would be a charity if this example were copied as far as possible in this country.

"The Beacon" on the New Methylated Spirits.—"Watchman," in the *Beacon*, has something to say on the New Methylated Spirit Regulations which strikes us as eminently sensible. After explaining that the addition of mineral naphtha makes the spirit altogether unsuitable for emulsion-making and other photographic purposes, he doubts whether the addition will deter the more degraded class of whisky-drinkers. He does not believe in depriving a whole people of its cakes and ale for the sins of the few, and says he would add to the spirit such poisonous matter as, while it would be fatal to the drunkard, would not interfere with its employment in science and the arts. The regulation has been adversely criticised all round. Who, we wonder, is the meddlesome ornament of the Laboratory at Somerset House that has doubled the unpopularity of the Inland Revenue among such a large section of Her Majesty's subjects?

GAS-REGULATOR CHECKS.

The following experiments, made to attain greater safety in the use of compressed oxygen, will probably be of interest to many readers of The British Journal of Photography.

When recently investigating, with Mr. Budenberg, of this city, some causes of explosions alleged to be due to, or assisted by, the use of gauges, we proved that, under the ordinary conditions of the use of compressed gas by lanternists, the presence of either gauge or regulator is not required to obtain ignition of combustible matter, for the ordinary connecting arrangements and stem of a regulator or gauge (without a check) are long enough to allow of the compression of sufficient heat to ignite tinder with compressed air only, and we infer that, with compressed pure oxygen, even a shorter tube would suffice. The experiments show that, with ordinary couplings attached to oily cylinder valves, there has been a source of danger which, although very real, happily has not made itself frequently apparent, and, no doubt, some explosions caused thereby have led to the gauges being condemned.

Therefore I have made a few experiments as to the practical value of inserting an efficient check in the entrance to a Clarkson's Duplex Regulator, and I find that, when it is arranged to pass gas under a high pressure at a slow speed, it permits enough to enter the regulator for three blow-through jets; but, with mixed jets of fairly large bore, $\frac{1}{17}$" (=No. 53 Lanc. steel-wire gauge) diameter, there was not enough for two jets to work at their best, although they had to pass their proportion of coal gas with the oxygen. I therefore opened the check (the Jackson Check being used, as the best I am acquainted with), so as to pass the oxygen more readily, but, at the same time, prevent such an inrush as would produce the ignition of oil in its liquid form, and found that abundance of oxygen was then obtained for two jets; but, when all three were acting together, there was a slight falling off in the light, although it is probable an ordinary non-critical assembly would not have perceived it. It is, however, seldom that all three jets are required to work at their full capacity at the same time, and, as those used are much larger than ordinary commercial jets, with the latter a full supply would be obtained, for they rarely exceed $\frac{1}{20}$" in the bore; a full supply would also be obtained for larger jets by opening the check a little more, and it would still maintain the necessary conditions for safety.

I am therefore led to the conclusion that users of single and biunial lanterns with blow-through jets, who probably form the majority of amateur lanternists, would be quite protected from the risk by adopting the Jackson Check in their regulators, and in fact in any tube stopped at the outer end intended to draw off high-pressure oxygen: the check should be placed in the nozzle close to the part in contact with the cylinder valve. Users of mixed jets, on screens up to eighteen feet square, can have a better light than is generally seen at lantern

entertainments with all three jets of a triple lantern in use together for effect slides, while with only two jets more gas is supplied than can be used.

The pressure in the oxygen cylinder during the earlier trials was about 90 atmos., and during the later trials about 30 atmos.; but no difference was perceptible on that account, in consequence of the regulator, for the check does not diminish the quantity of gas more than has been pointed out, and does not affect the pressure which is maintained even by the regulator. The recommendation to employ checks in regulators is not intended for exhibitors on twenty-five or thirty-feet screens, who have special jets and appliances, and use special care with everything. H. M. WHITEFIELD.

CELLULOID FILMS.

[A Communication to the West London Photographic Society.]

For many years past it has been a great aim in photography to substitute a lighter material than glass as a support for the sensitive film for negatives, and until the introduction of celluloid no substance was found to be capable of supplanting glass for the purpose.

Celluloid, as a new material in the arts, dates back to about the year 1869. It is a hard, durable substance, almost entirely unaffected by acids or alkalies, unchangeable under ordinary atmospheric conditions, and is very tough. It is rendered plastic by heat, and can be moulded into any desired form. Alcohol and acetic acid act upon it, partially dissolving it. It is soluble in acetate of amyl, forming a hard, transparent varnish. The manufacture of the celluloid sheets used in the preparation of negative films is somewhat as follows:—

A pile of pure white paper is acted upon by nitric and sulphuric acids, converting it into nitro-cellulose. It is washed to free it from the acids, and then treated with wood spirit and camphor, producing a jelly-like block, which is then subjected to great pressure, which is sustained for a period of several weeks. The block, from which most of the spirit is now evaporated, is put into a machine something like a planing machine, and is cut into shavings or sheets of the thickness of the film required; each shaving or sheet, which measures 60 × 20 inches, is now hung up to dry for a period of about three months, in order to thoroughly season it and prevent any after-change. Each sheet is then taken and rolled under heavy pressure between heated metal plates, to obliterate the marks of the cutting knife. The metal plates are either polished or grained, according to the surface required, the polished giving the smooth film and the grained the matt surface. Both kinds are used, but I much prefer the smooth, as those films which have the matt surface at the back take a little longer to print, and are also very liable to become scratched. They are, however, good for retouching. The gelatine emulsion is spread over the sheets by means of special appliances, and which produces a film of gelatino-bromide of silver of great uniformity. The emulsion is the same as that used in the preparation of dry plates, and the film, when dry, is precisely the same as a glass plate, with the exception that the support is celluloid instead of glass.

The great advantage of celluloid films is, of course, their lightness and portability. A dozen half-plate films, with their packing, weigh about four ounces, while the same number of glass plates will average three pounds, whilst, in thickness, one gross of films in packets will occupy four inches, and one gross of plates fourteen inches. There is, too, no fear of breakage, and halation, so common with glass plates, is almost entirely obviated by the use of films. The films can be kept flat for exposure in the dark slide by several means. I myself use carriers, which are light and inexpensive, consisting of cards with metal grooves at the ends. The films can be easily slipped into the grooves, and are then ready to place in the slide like glass plates. I have found them very effective. For very large sizes the plan adopted —first, I believe, by Mr. Warnerke—consists of sticking the films down upon a surface, which always remains tacky. This method is a very good one, but care must be taken to keep dust from the surface. I have used, with very great advantage, carriers which are slightly curved, as this form very materially aids even definition when using large stops in the lens.

The exposure required is the same as that for glass plates. I have found there is no difference whatever, whether the emulsion is coated upon glass or celluloid.

For development any of the usual developers are suitable, and the films will lie flat provided the bottom of the dish is first wetted. It is not necessary to wet the films previous to development, except for large sizes. They are fixed in the usual fixing bath, taking care that the edges do not curl up out of the solution and thereby escape fixing. The films when fixed are well washed, and then hung by small clip on a line to dry. Intensification or reduction can be effected without difficulty by means of any of the usual formulæ. The films can be easily varnished with a varnish that does not require heat in drying, such as amber in chloroform, or gold size thinned with benzole. The varnish is applied by means of a soft brush. A simple plan, however, which I have lately tried and which seems to be very simple and effective, is to dip the films after washing and before drying into a water varnish consisting of pale shellac dissolved in an aqueous solution of borax. This dries with a very hard impervious coating.

There are many useful applications to which celluloid films may be applied. In Moessard's cylindrograph, which takes panoramic pictures two or three feet in length, the films are inserted in a slide which is bent to form the segment of a circle. Another useful application is in making stereoscopic pictures. The stereoscopic negative can be cut with a pair of scissors, and the halves transposed and mounted upon glass, when the prints taken will not then require reversing. Very good cloud negatives can be made with the films which may be printed from either side. In cases where reversed negatives are required, as for carbon printing or collotype, a celluloid negative will be useful, and, although one does not get absolute sharpness by printing in the ordinary manner, it can be improved by placing the frame containing the negative at the bottom of a box, so as to cut off all oblique rays. By this means one can get sharp pictures. For focussing screens, too, the matt celluloid forms an excellent substitute for the ground glass.

I should like to say a word as to storage of negative films. They should be kept like plates in a dry place and away from gas fumes, but, above all, the films should not be subjected to too much pressure. On account of their being unbreakable, one is very apt in travelling to pile a great many things upon them, and this is often the cause of peculiar insensitive markings upon the negative. Captain Abney has pointed out that the effect of pressure upon a gelatino-bromide film is to destroy the sensitiveness of the parts pressed. And now, in conclusion, I hope the few hints I have given will prove of service during the coming season, when, no doubt, celluloid films will be very extensively used. J. D. ENGLAND.

THE PHOTOGRAPHIC SOCIETY'S LECTURES.—III.

PHOTOGRAPHY AS A BRANCH OF TECHNOLOGY.

THE invitation conveyed to me by your Council, to assist in promoting a scheme of photographic technical education of a more complete character than that provided by the elementary schools is in such complete accord with the principles which I have always held, and which I have occasionally promulgated through other channels, that I felt it an almost imperative duty to respond to the invitation, in spite of the numerous other claims upon my time, for I believe that, if the Photographic Society will throw itself with zeal into some well-organized scheme in this direction, a great benefit will be conferred upon the cause of technical education in this country. I will even go so far as to express the belief that a work of national importance may be accomplished.

THE DAWN OF PHOTOGRAPHY.

It may, perhaps, appear as preposterous to dwell upon the importance of photography before the members of this Society as it would be for a merchant to address the Chamber of Commerce on the importance of trade, or for a financier to lecture to an institute of bankers on the importance of banking. Nevertheless, it is a common experience that those who are actively engaged in the prosecution of some special kind of work often take a narrow view of their own labours; they have no time to take a bird's-eye view of the whole subject, and an independent outsider may sometimes do good service by gathering up the odds and ends of scattered observations, and fitting them into their right positions in the general plan. If any justification is required from me for addressing a Society composed so largely of photographic experts, I need only plead that, as a teacher of technical chemistry, I have felt it necessary to give full recognition to the claims of photography as an important branch of technology. It can no longer be ignored that photography has penetrated the arts and sciences to an extent that has raised it to an exalted position among technical subjects, and as such it has not yet received its proper recognition in this country. From the very dawn of its discovery, the importance of its applications was foreseen, although it is only in our own time that the realisation of this importance is being witnessed. We need not commit ourselves to the extravagance of Paul Delaroche, the artist, who, during the excitement caused by the revelation of the Daguerreotype process, is said to have declared, "Painting is dead from this day!" The art of the painter has not been killed, but it may fairly be claimed that it has been aided by photography; the art of the engraver has been revolutionised by its means. The prophetic utterance of a writer in the *Edinburgh Review* for January, 1843, has been fulfilled: "The art of photography, or photogeny, as it has been called, is indeed as great a step to the fine arts as the steam-engine was in the mechanical arts; and we

have no doubt that when its materials have become more sensitive, and its processes more certain, it will take the highest rank among the inventions of the present age."

All who are familiar with modern photographic methods will admit the truth of this prediction; the materials have been rendered more sensitive, and the processes more certain. The sensitiveness has been increased to a degree that would probably astonish the writer of the passage quoted, and the certainty of the processes is such that the amateur photographer exists by thousands. It is, perhaps, this last circumstance which is responsible for the identification of photography in the public mind with the taking of portraits and landscapes. These are, no doubt, very important applications of the subject, but photography is not synonymous with portraiture and the taking of scenery; if we allow this view of the subject to prevail, it cannot but have the effect of narrowing down the general estimate of its importance, and of thus injuring its claim to take high rank among technical subjects. We are here, I imagine, to proclaim the far-reaching importance of our subject. Every one knows with what beautiful effect the photographer can reproduce a portrait or a piece of scenery, but what is not so generally known to the public at large is the enormous service that photography has rendered to other branches of science. If I dwell, therefore, upon this application of the subject, it is not for the purpose of depreciating its application to art, but rather for the purpose of exalting both aspects.

Photography in Astronomy, Physics, and Chemistry.

The modern dry plate has insinuated itself into every branch of practical science; whenever a phenomenon of a temporary character has to be registered with absolute accuracy, where the human eye fails, owing to the faintness of the object or the rapidity with which the phenomenon occurs, there the aid of the dry plate is invoked. The application of photography to astronomy has, as is well known, relieved the eye of the astromoner and curtailed the work of the observatory to an extent bordering on the marvellous. A faint nebula, which by eye observation may take many years of wearying labour to represent in the form of a drawing, in the course of a few hours impresses its image in all its fineness of detail on the photographic plate—a memorial for future ages of the true form of the nebula at the time of its being photographed. Stars which appear as points of light in the telescope are shown by the photographic plate to be small nebulæ, and stars and nebulæ which have altogether eluded the most powerful telescopic search impress themselves on the sensitive film. All this and much more in the same direction is such familiar knowledge now, that it is only necessary to mention the facts, nor need I remind you how the photographic plate is being utilised for the photo-astrographic survey of the heavens, and in astronomical spectroscopy for the permanent registration of the solar spectrum and the spectra of the stars. The "Draper Memorial" is one of the latest examples of the utility of photography in the observatory; it is no exaggeration to say that one of the grandest problems of modern science —the question of stellar evolution—will be rendered capable of scientific discussion by this application of the gelatino-bromide film. The modern astronomical observatory is in fact equipped for photographic work quite as much as for observational work, and the photographer has become as necessary as the observer.

In physics and in chemistry also the photographic plate has been added to the weapons of research. Here it has been used to record phenomena which occur with such rapidity as to elude visual perception. What would the Edinburgh Reviewer of 1843 have thought of the possibility of photographing a soap film in the act of breaking, or a liquid drop in the act of falling? Yet, as you all know, Lord Rayleigh and Mr. Boys have succeeded in doing this. Or take, again, the application of the sensitive plate to the elucidation of the phenomena of gaseous explosions by Professor Oettingen, who, by using a rapidly rotating dry plate, was enabled to show the intermittent character of the flash produced by the explosion of hydrogen and oxygen. Professors Liveing and Dewar have also succeeded in photographing the spectrum of a mixture of exploding gases. In spectrum analysis, in fact, the services which have been rendered by photography cannot be over-estimated. The astronomer, the physicist, and the chemist must have for reference complete and accurate charts of the spectra of the chemical elements. The early maps of Bunsen and Kirchoff, and the splendid "Spectre Normale" of Angstrom were drawn by eye observation after years of laborious work, and with injury to the eyesight of the observers. These maps are now produced by photography without any tax upon the eyesight, and with an amount of detail that renders the early maps—executed with such painful labour—but mere skeletons as compared with their photographic representatives. The spectra can, moreover, be compared far more readily and with much greater accuracy by the photographic method. The method of eliminating the lines in the spectrum of one element, due to the presence of a trace of some other element as an impurity, which we owe to Professor Norman Lockyer, has only been rendered possible by photography. If the residual lines common to several elements, and which cannot be traced by this means to any known element, should lead to the discovery of new elements or to the resolution of known elements into simpler forms of matter, the credit must be given to the photographic method.

In Spectroscopy, Meteorology, and Geology.

But it will be safer to confine ourselves to what photography has actually done for science than to attempt to enter the regions of speculation. The case to be made out is such a good one that there is no need to draw upon the imagination. Thus, again, in the region of spectroscopy, the relationship between the constitutions of chemical compounds and their power of absorbing certain definite light waves, as investigated by Professor W. N. Hartley, may be said to have been discovered by means of photography, because the absorption is, in the case of colourless liquids, exerted beyond the limits of the visible spectrum. In meteorology the photographic plate has also been of the greatest service, and a British Association Committee has been formed for the purpose of stimulating work in this direction. Most of those present are, no doubt, familiar with the more striking results achieved by meteorological photographers. The fleeting forms of clouds can be registered with absolute fidelity, and, by an ingenious arrangement of electrically connected cameras, the height and rate of motion of clouds has recently been determined by the aid of photography. The character of the electric discharge in the laboratory has been studied photographically by Mr. Shelford Bidwell and by Professors Oliver Lodge and C. V. Boys, and the large-scale discharge of the lightning flash has been made to impress itself on the photographic plate. The results are known to all; the conventional zigzag "fork" appears to have no existence in nature. The destructive effects of wind storms on buildings can also be studied in photographs with an amount of accurate detail that it would be impossible to represent by any other method; and I am informed by Mr. G. J. Symons that important conclusions concerning the nature of the atmospheric movement have been arrived at by the examination of such photographs.

Passing on to other applications of photography, it is obvious that, in geographical and ethnological exploration, the camera has become an essential part of the traveller's equipment. In geology, again, the aid of the photographer has been called in, and with such good results that a British Association Committee has been called into existence, and has been doing excellent work in collecting and registering geological photographs during the last two or three years. In these photographs, sections are recorded with a fidelity which it would be impossible to equal except by laborious sketching. Where time is an object, as in the case of sections only temporarily exposed, the camera is invaluable. Moreover, the value of such photographs will increase with time, in the same way and for the same reason as the photographs of the starry heavens; for, while the latter, taken at the time of the present celestial survey, will, by comparison with photographs taken in the far distant future, reveal relative movements among the stars, the geological photographs of the present period will, by future comparison with the localities registered, furnish incontestable evidence of the slow course of geological change.

In Biology, Chronophotography, and Anthology.

In Biology photography has been utilised with great advantage, and will, no doubt, become of still greater service in the future. There is no reason why the dry plate, which has already largely superseded the eye in astronomy, should not also relieve the eye of the microscopist. Many biological works have been illustrated with great success by means of photo-micrography, and, even in purely systematic works, such, *e.g.*, as Marshall and De Nicéville's *Butterflies of India*, photographic illustration has been adopted with success. In studying microscopic forms of life, where an evanescent phase of life-history may be full of profound significance, the photographic plate might well replace the eye in those cases where prolonged and fatiguing observation has hitherto been found necessary. The fleeting phases of expression, of such importance in comparative psychology, have been caught and fixed on the photographic plate with a natural fidelity that it would have been impossible to attain without such aid. Mr. Darwin's work on *The Expression of the Emotions* was, as you are aware, illustrated by photography even before the dry plate had been worked up to its present exalted degree of sensitiveness.

The application of photography to the analysis of the movements of animals has been made familiar through the remarkable photographs which Mr. Muybridge has on many occasions brought under our notice in this country. Among other results recently achieved, I need only refer to those wonderful pictures of animals in motion, taken by Messrs. Marey

and Anschütz. Such results as these are not only interesting illustrations of the high state of perfection to which modern photography has been developed, but they are of the highest value in elucidating the mechanism of animal movement, and of the flight of birds. The introduction of photography into this branch of animal mechanics has led to a complete revision of pre-existing conventional notions, and the indirect effect of such photographic analysis of the phases of motion on the work of the artist is of an importance that cannot be over-estimated.*

In the department of Anthropology photography has served for the faithful registration of race types, and Mr. Francis Galton's method of composite portraiture is familiar to all. In his recent studies of "finger marks" in connexion with heredity, Mr. Galton has also found it indispensable to work from photographic enlargements.

This imperfect sketch of the scientific applications of photography might well be followed by a much more extended list of its achievements in the domain of art. But I do not feel myself justified in taking up more time in telling you what you already know, and there are no doubt many present who are far more competent to deal with this aspect of the subject than I am. I cannot help thinking, however, that it would materially help the cause of technical instruction in the desired direction if some competent authority among you were to draw up a complete statement of the benefits which have accrued to art, both abstract and applied, by the introduction of photographic and photo-mechanical methods.† RAPHAEL MELDOLA, F.R.S.

(*To be continued.*)

THE PHOTOGRAPHIC SURVEY OF WARWICKSHIRE.

A MEETING of the Photographic Survey Council of Warwickshire was held on Feb. 1st at the Colonnade Hotel, Mr. J. B. Stone (President) in the chair.

The President said that it had been something like a year and a half since the scheme of a photographic survey of the county was floated. It might appear to the outside world that nothing had been done and no progress had been made during the interval; but, on the contrary, in all directions most satisfactory labours had been bestowed on the work, which was so excellent that it would be impossible for him to find words to describe its character. It had been gratuitous and disinterested work, and was of such a high standard of excellence in itself, from the technical manner of production, that he ventured to say that the series of pictures that had been sent in were unequalled in any similar collection throughout the world. He did not speak without a very large experience of photographic work, and he believed they might safely challenge the whole world for local work such as had been sent in for the survey. The character of the objects portrayed was as varied as one could desire. They had archæological features in the form of hundreds of churches they valued and wished to preserve recollections of; they had old mansions, not only single views, but some of them taken from a dozen different positions, that preserved all their beauty; and, in addition, they had photographs of Warwickshire lanes, cottages, and peasantry, all so much associated with the works of Shakespeare and other writers who had made Warwickshire famous. The fact that these views were associated with the literature of the county would make them of enormous value to posterity. So far, the appeal to the voluntary efforts of distinguished amateur photographers in the county had been responded to so liberally, that they had received from he did not know how many contributors as many as 700 pictures for the collection. They would fill something like 500 frames, and it was proposed that they should all be mounted similarly, and placed in frames of one size, so that the collection would be a uniform one. He had already waited upon the Mayor, and he, with the greatest possible courtesy and willingness, at once adopted the suggestion that the photographs should be publicly accepted, and that there should be a formal public handing over of the views, which should be kept for reference. The Mayor, following out the idea, had consulted with the Free Libraries Committee, the Art Gallery Committee, and Mr. Whitworth Wallis, and it was now settled that there should be a public exhibition of the photographs in the Art Gallery during the spring and summer months.

Mr. J. H. Pickard announced that he had received letters from several amateurs and professional photographers offering to assist the council. He also stated that, although at the outset photographic societies in other towns in the county had promised assistance, no photographs whatever had been received from them, and the whole of the work had been done by the members of the Birmingham Photographic Society. It was further announced that an application had been made on behalf of the Birmingham Old Library, asking for a duplicate set of views, and offering to place at the disposal of the council, for the purposes of copying, a number of old local illustrations, &c., in the possession of the library.

Mr. Simkins, the curator, undertook the work of producing a catalogue descriptive of the photographs to be exhibited.

* Prof. Du Bois-Reymond deals with this in the address referred to. Some of Prof. Marey's recent results are described in *Nature*, vol. xlv. p. 228.

† Since the above was written, Professor E. du Bois-Reymond's address to the Royal Academy of Sciences of Berlin on "The Relation of Natural Science to Art" has appeared in *Nature*, vol. xlv. pp. 209 and 234.

Our Editorial Table.

THE PHOTOGRAPHER'S INDISPENSABLE MONTHLY (Adams & Co.) reappears after two months of suspended animation. The new Editor tells us that he has orders to avoid personalities. There is much wisdom in the order. As he elects to correct the printers' errors of his contemporaries, perhaps he will tell us what he means by giving the Harvard lens a "twenty-fourth aperture" (*sic*), and whether Mr. *Ram*, of Pennsylvania, should not read Mr. *Rau*. We are happy to recognise so many quotations from these columns in the *Indispensable*, but we should like to see them correctly printed, if even they are not acknowledged. Otherwise its pages are entertaining, and its advertisements a source of grievous temptation to buyers of apparatus, &c.

INSTRUCTION IN PHOTOGRAPHY.

By CAPTAIN W. DE W. ABNEY, C.B., F.R.S., &c.

WE are pleased to find that Messrs. Piper & Carter, 5, Furnival-street, E.C., have brought out a ninth edition of this standard work, in which everything has been brought up to date. Among the new matter introduced are "The Measurements of Densities of Negatives and Depth of Prints;" "On Lenses, Stops, and Pinholes;" "Artificial Lighting by Magnesium and Electricity." This differs from the previous editions in that the first place, as regards instruction, has been accorded to gelatine, collodion, which has hitherto occupied that position, being given a second place. We are glad to observe that the French system of weights and measures, which was given in the last edition, has been discarded, and "parts" substituted. The low price of the work places it within the reach of every one.

THE YEAR BOOK OF PHOTOGRAPHY.

Edited by T. C. HEPWORTH, F.C.S. London: Piper & Carter.

WITH the reins of our contemporary, the *Photographic News*, Mr. Hepworth also takes hold of those of its annual, the *Year Book*, which becomes more plethoric year by year. The one for 1892 before us contains many excellent articles by good writers, and a compendium by the Editor of the leading novelties of the past year. It is embellished by a collotype, printed by Thevoz & Co., from a negative by the Editor. It also contains a large number of advertisements.

TRADE CATALOGUES.

MCGHIE & CO., GLASGOW.—As the best got-up of those now before us, we select that of Messrs. McGhie & Co. for the first place. It contains 160 pages of well-selected, copiously illustrated, and nicely printed matter, in the form of descriptions of lenses, cameras, shutters, lamps, chemicals, and apparatus in general. All the requisites for fitting up the studio are here to be found.

D. NOAKES & SON, GREENWICH.—This is a lantern catalogue, and contains descriptions of the various lanterns and appliances made by this firm, together with a list of the slides kept in stock. This is prefaced by practical hints on the management of the lantern, written by members of the firm, which are replete with good common sense. We, however, question the prudence or good taste which leads them to reproduce a letter, which appeared in this JOURNAL about four years ago, criticising the award of the prize which had been given to a rival maker for his Docwra lantern. It looks as though they were seriously chagrined, and were taking the matter too much to heart.

LOEBER BROTHERS, NASSAU-STREET, NEW YORK.—Nothing shows more forcibly the operation of the high Customs tariff on European-made photographic goods than a comparison of the prices of identical productions in a good American and English price list. On the more important of the photographic imports this represents forty-five per cent., which, with other dues, brings the added price up to fifty per cent., and this, of course, must come eventually out of the pocket of the photographer. Much of the American apparatus is *sui generis*, and hence we never examine a well-illustrated catalogue emanating from the United States without acquiring new ideas as to design and construction. In cameras we find several designs with which we in this country are not familiar. The Book contains particulars of most of the better known lenses of European make, together with chemicals, plates, and accessories.

No. 1730.—"An Improved Photographic Camera." Complete specification. A. A. DEHORS.—*Dated January* 28, 1892.

PATENTS COMPLETED.

IMPROVEMENTS IN MOUNTS FOR PHOTOGRAPHIC PICTURES.

No. 20,770. JOHN REYNOLDS, 31, Fort-street, Brushfield-street, Spitalfields, Middlesex.—*January* 2, 1892.

THE object of this invention is to provide amateurs with a facile means of mounting their photographs, whether those having a glazed surface, or a "matt" surface, and, at the same time, to ensure that the glossy surface of the one, or the smooth, dead surface of the other, shall not be injured, as is now frequently the case when applying damp thereto in the act of mounting them.

To this end I construct mounts somewhat after the manner of photo-album leaves—that is, I prepare a piece of pasteboard, which is to form the frame, embossing, or otherwise ornamenting, the opening or openings which are to receive the pictures and present them to view. This frame I attach by gum, or other adhesive material, to a backing of pasteboard in such a manner that the inside edges of the opening or openings will be free of, or unattached to, the backing, and that one side or end of the pasteboard frame will be unattached, as is usual, to provide for the insertion of the picture.

A material difference between this mode of making the mount or album leaf is, that I omit the spacing-board which has hitherto been necessary to provide a space for the reception of the mounted picture.

The injury to the photograph above indicated is avoided by rendering it unnecessary to mount it upon a backing card prior to inserting it in place, and the omission of the spacing layer of cardboard ensures a proper grip of the inserted picture between the backing-board and the frame or mount.

IMPROVED PHOTOGRAPHIC PLATE WASHER.

No. 20,951. SAMUEL HENRY SMITH, 102, The Parade, Leamington Spa, Warwickshire.—*January* 2, 1892.

MY invention consists in improved apparatus for washing photographic negatives, my object being to secure in one apparatus, amongst others, the following principal advantages:—

1st. The washing of photographic negatives of one or various sizes in an inclined tank fitted with racks, in which the plates are placed with the sensitised films downwards.

2nd. In so arranging the water-supply pipe as that the incoming water shall splay upon the bottom of the inclined tank, and prevent the stripping of the film.

3rd. So mounting the syphon that the whole of the hyposulphite solution, which gravitates to the lowest corner of the tank, shall be discharged.

IMPROVEMENTS IN MAGIC LANTERN SLIDES.

No. 2165. GEORGE FREDERICK LUTTICKE, 23, Lansdowne-place, Brighton.—*January* 9, 1892.

MY invention refers to the construction and arrangement of jointed figures, or objects, for use in magic lanterns. The said figures, which, made of any suitable material, may be jointed in any suitable way, part, or parts, are, where necessary, provided with pins, or other suitable stops, regulating the extent of movement of the limbs or parts of the body. Part or parts may be pivoted to a platform, whilst other parts may be arranged to move by means of a fork at the end of a lever bar, or the like, moving a pin travelling in a slot, or by an equivalent contrivance. In order to cause one limb or part to impart motion to another, I may employ a connecting rod conveniently arranged, or I may form two parts or limbs in one piece, suitably pivoted to a convenient part of the body. When two or more figures are shown, I may connect one with another in any plausible way, for example, by a string, wire, or the like, and by that means effect a controlling action on the movements of the limbs, parts, or the figures themselves.

A weight or spring may be conveniently arranged to act on a jointed part or parts to cause or control motion.

I reserve to myself to use any suitable means for actuating the said figures.

The claims are:—1. In a magic-lantern slide, the combination of a figure or figures, or object or objects formed with articulated limbs or parts, and means for imparting differential or other movements to such limbs or parts substantially as herein shown and described. 2. In a magic-lantern slide, the combination of a figure or figures formed with articulated limbs or parts, and means for imparting differential or other movements to the body or bodies, and to such limbs or parts substantially as herein shown and described. 3. In a magic-lantern slide, the combination of a moving figure or figures formed with articulated limbs, or bodies, or other parts, means for connecting one moving part with another, or other means for imparting differential movements to a part or parts of the figure or figures, and means for connecting, and thus imparting, differential movements to other parts thereof substantially as herein shown and described. 4. In a magic-lantern slide, the combination of a moving figure or figures formed with articulated limbs or other parts, forked or other levers controlled by counterbalance weights or springs, for imparting differential movements to such limbs or parts, stops for limiting the movement of the levers, and means for giving motion to the figures substantially as herein shown and described. 5. In a magic-lantern slide, the combination of a moving figure or figures formed with articulated limbs or parts, springs, and stops for controlling the movements of the limbs upon the movement of the figure or figures, and means for giving motion to the figure or figures substantially as herein shown and described. 6. In a magic-lantern slide, a moving or other figure or object formed with articulated limbs or parts, forming two of such limbs or parts in one, so as to move upon one centre substantially as herein shown and described. 7. In a magic-lantern slide, the employment of springs or weights to act upon a jointed part or parts, to cause or control motion substantially as herein shown and described. 8. In a magic-lantern slide, the combination of a figure or other object formed with articulated limbs or parts, and stops for limiting the movements of such limbs or parts substantially as herein shown and described. 9. In a magic-lantern slide, the combination of a figure or other object formed with articulated limbs or parts, a pin or the like upon one part, a guide slot in a fixed object to receive the pin, and a forked lever or the like to give motion to such part substantially as herein shown and described. 10. In a magic-lantern slide, the peculiar arrangement of parts substantially as herein shown and described.

PHOTOGRAPH EXHIBITORS.

No. 19,911. CARL GUSTAF SODERSTROM, Sixteenth and Lawrence-streets, Denver, Arapahoe, Colorado, United States of America.—*January* 9, 1892.

MY invention relates to a novel form and construction of photograph exhibitors, and the object of my invention is to provide a device to take the place of photographic albums, or, at least, to answer every purpose of the album, while possessing many novel and interesting features entirely foreign to albums and picture receptacles heretofore used, so far as known to me.

The invention consists of a rotating frame located within a suitable chamber, and provided with pivoted radial arms adapted to grasp photographs, cards, or pictures, these arms being capable of such manipulation by depressing a key fitting over the axis of the frame that any picture, card, or photograph may be thrown upward and exposed to view, and retained in sight until the key is raised, when the arm returns automatically to the concealed position, when another picture may be seen by actuating another arm.

The device is designed to be located in a recess of suitable depth formed in the table, the foot of the frame being rigidly secured to the base plate or bottom of the recess, while the top of the table conceals the mechanism. In the centre of the top, however, is formed an opening for the insertion of the key, which, when first depressed, releases a spring-actuated arm, which rises to the vertical position, said arm carrying a contents card, upon which may be written the names of all the persons whose pictures are held by the device, and the corresponding numbers of each picture, since each arm is numbered, and after the pictures are arranged, the contents card is formed to correspond.

The arm carrying this card forms a portion of the top of the table when in a horizontal position, but when upraised leaves a slot therein; it is through this slot that the picture subsequently rises as the actuating key is used.

CAMERA CLUB.—The Retouching Classes meet on Wednesdays and Fridays at eight p.m.; Teacher, Mr. Redmond Barrett. February 1, Smoking Concert. 4, Mr. S. Herbert Fry will demonstrate *A New Enlarging Lantern* (*without Condensers*), and the Incandescent Gas Light Company's light will be shown. 8, Elementary Lecture No. 7, *Intensification and Reduction*, by Mr. Lyonel Clark. 11, Commander C. E. Gladstone, R.N., *Architecture in Normandy and Brittany*, with lantern illustrations. 15, evening for testing slides. 18, Mr. S. B. Webber, *Some Experiments in Orthochromatic Photography*. 22, Elementary Lecture No. 8, *Platinum Printing Methods*, with demonstration of developing and of printing platinotype by artificial light, by Messrs. G. Davison and E. J. Humphery. 25, Annual Meeting; Lantern Exhibition (pictures taken in Norway), by Mr. J. B. B. Wellington.

DUNEDIN PHOTOGRAPHIC SOCIETY, AND NELSON CAMERA CLUB, N.Z.—An exhibition of work by the above two Societies was held at Dunedin in November, and was open three weeks. This was the occasion of the Dunedin Photographic Society's second annual exhibition, and it was thought that, if the two Societies combined in exhibiting, a healthy emulation would be created, and the cause of art prospered. These expectations have been realised, and it is intended that in future the two Societies will give material assistance at each other's exhibitions, and other Societies will be invited to join. The total number of exhibits was 191, of which Dunedin contributed 142, and Nelson the balance. Silver printing seems to be the favourite method of the Dunedin Society, nearly all of the exhibits being silver prints. Nelson, on the other hand, affects platinum and bromide printing. Every description of subject was represented on the walls, from scenery, pure and simple, to portraiture.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
February 8	Darlington	Trevelyan Hotel, Darlington.
" 8	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
" 8	Lantern Society	20, Hanover-square.
" 8	Norfolk and Norwich	Bell Hotel, Norwich.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

FEBRUARY 2,—Mr. J. Spiller, F.C.S., in the chair.

Professor Meldola's lecture, *Photography as a Branch of Technology* [see page 87], was read by Mr. A. MACKIE, in the unavoidable absence of Professor Meldola through illness and a domestic bereavement.

The CHAIRMAN regretted the absence of Professor Meldola, who was one of the leading technical professors. The paper was one of national importance. Referring to Mr Warnerke's recent lecture on *Photo-Technical Education on the Continent*, he said that there were no such institutions to be compared to those in Vienna and Berlin in this country. He instanced the difficulty of gaining instruction in collotype work, facilities for which did not exist. In preparing the paper, Professor Meldola had conferred a high compliment on the Society, and he moved that the best thanks of the Society be awarded to him, coupled with regret and sympathy with him in the sad circumstances that prevented his attendance.

Mr. W. REDFORD seconded the motion, which was carried unanimously. The lecture was in accord with the principles laid down by Mr. Bolas, on which technological instruction should be given. The difficulty was to find competent teachers, as many experts did not understand the underlying scientific principles. Even if lecturers could not themselves produce good work, yet, by pointing to better examples, they might in time raise men who would become capable teachers. The affiliation scheme promised to do something in this direction, and Professor Meldola's advice would be of great assistance to the delegates in their deliberations. He hoped the affiliation would lead to some such result as Professor Meldola desired.

Mr. W. England, Mr. A. M. Levy, Mr. W. H. Harrison, and Mr. J. R. Gotz agreed with many of the points raised in the lecture, the latter emphasising the necessity of a knowledge of photography in surgery and pathology.

Mr. H. M. ELDER had the advantage of Professor Meldola's personal assistance, and had assisted him in preparing the lecture. He supported the suggestion for the foundation of an Institute, and instanced the work carried on by the City and Guilds of London Institute as going on well, thanks to Professor Meldola and others. For the Institute they wanted good men as teachers, and their object should be to turn out, not elementary prize-winners, but thoroughly capable men, qualified to undertake the scientific departments of manufacturing businesses. If the Photographic Society of Great Britain set itself to the labour, in five or ten years they might establish a good teaching Institute.

Mr. S. T. CHANG said that fifteen years ago, in China, he commenced work in the collodion process. No facilities for instruction existed there, as people seemed to be afraid of photography; but it was now becoming widely introduced, on account of dry plates.

Mr. A. MACKIE said that, if the attendances at the lectures had not been what were anticipated, the one they had just heard repaid the Committee for the labour expended. He thought many members under rated the importance of the affiliation movement. He considered its main object should be to create a central institution, where members of Societies could meet and exchange ideas.

The meeting then closed.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 28,—Mr. A. Cowan in the chair.

Messrs. G. Austin and E. Milner were unanimously elected members of the Association.

The HON. SECRETARY having referred to a suggestion made that the Photographic Societies should move in the matter of the new methylated spirit, the CHAIRMAN mentioned that the subject had been brought before the Photographic Society of Great Britain at its last meeting.

Mr. G. W. ATKINS then moved, and Mr. L. MEDLAND seconded, "That this Association has heard with satisfaction that the Photographic Society of Great Britain has it in contemplation to represent to the authorities that the present regulations with regard to the sale and use of methylated spirits unfavourably affect photographers, and the members hope that the matter will be brought forward as speedily as possible."

The resolution was carried unanimously.

Mr. J. R. GOTZ exhibited his new film carriers, for use in the ordinary dark slide. He also showed several of the new Zeiss lenses constructed by Suter, of Basle, under special licence from Zeiss. Up to the present there were only three licensees, Voigtlander being one, and Suter the only non-German house, so far as he (Mr. Gotz) was aware. He thought that the lenses were a step in advance of the aplanatic system of Steinheil. Having reviewed the constructions of various doublets since that time, he remarked that Suter was the first exponent of the new Jena glass. He figured the curves of one of the Series III. lenses, and also gave the radii, mentioning that baryta crown, silicate crown, and light flint were used in the elements. The Jena people made at least a hundred different kinds of glass, and also exactly the same kinds as those made by Chance. The new glasses were of entirely new metal. In reference to the construction of these lenses, he said that the licensees bound themselves not to depart from the forms covered by Zeiss's patent.

Mr. W. E. DEBENHAM said he had examined one of the Zeiss anastigmats, and found it really a wide-angle lens, as wide as many lenses professing to be wide angle. With a focus of eight and a half inches, it covered a circle of fifteen inches, which was as much as people could expect from a wide-angle lens. It was a trifle more rapid than most rapid symmetrical or rapid rectilinears. It also had a most remarkable flatness of field. He had tested it for flatness of field against a rapid doublet lens of double the length of focus by a well-known maker. The field of the latter should have been flatter than that of the anastigmat; but, on tracing the respective images on a twelve-inch plate, the anastigmat gave sharpness up to within an eighth of an inch from the margin, and the rapid doublet to within a greater distance from the edges. He had formed his opinion from actual measurements made while another person focussed. These lenses were the greatest advance in photographic optics since the introduction of Steinheil's aplanats twenty-four years ago.

Mr. GOTZ explained the flatness of field by the fact that two components of the lenses were of silicate crown and light flint, which gave exceedingly small dispersion.

After a brief discussion on the well-worn subject of the best "backing" for plates,

Mr. J. S. TRAPP said he had tried the addition of acetic acid to the gallic acid developer for weakly printed gelatino-chloride prints, as suggested by Mr. Debenham. The solution produced much inferior results.

Mr. F. A. BRIDGE remarked that acetic and gallic acids were awkward to mix together. Acetic acid was one of the most treacherous things that could be used. He thought it unsafe to trust to one sample.

Mr. DEBENHAM advised the use of citric acid instead of acetic.

The meeting shortly afterwards closed.

Camera Club.—January 28, Sir George Prescott in the chair.—Mr. Haes showed a manuscript believed to be in Daguerre's handwriting, which had been discovered amongst Dr. Loewe's papers. The manuscript is a brief set of directions for Daguerreotype photography, and is marked and signed in Dr. Loewe's handwriting, "Received from Mr. Daguerre in the year 1840." The document, mounted between glass, will be exhibited in the club-rooms for about a fortnight. The Hon. Secretary exhibited a photo-electrotype, lent by Mr. Henry Sutton, showing the perfection to which the process had been brought. Mr. Gale then commenced showing his pictures, dividing the series into sets, illustrating various classes of landscape and country life. The slides were produced both on gelatine and on wet-collodion plates. Mr. Henry Stevens showed pictures of flowers, home groups, and some new studies of packs of hounds in the field, which were very fine. Other pictures were exhibited by Messrs. Cunningham, Noel-Cox, Elder, Sworder, H. E. Davis, Hess, Spencer, and Mills, and the evening concluded with some slides by Mr. Bingley, lent by Mr. W. England. On Thursday, February 11, Commander C. E. Gladstone, R.N., will lecture on *Architecture in Normandy and Brittany*, and the subject will be illustrated with lantern slides.

Hackney Photographic Society.—January 29.—The Autocopyist Company, London-wall, gave a demonstration of the Photo-autocopyist. The principle on which the process was worked was of the lithographic kind, but much simplified. After getting one print (about the depth of platinotype), a number could easily be obtained without daylight—a great consideration this weather. Mr. Clarke, of the Incandescent Light Company, Westminster, demonstrated the working of their light for lantern work. A very brilliant light was obtained, and a number of the members' slides were put through the lantern by the Hon. Secretary. The safety of the light was amply demonstrated by the bursting of a bag, the most serious thing which, it was stated, could happen. A slight explosion was, however, all that took place. The Hon. Secretary announced that the next meeting was on February 11, when Mr. T. C. Hepworth would give a lecture.

West London Photographic Society.—January 29, the President in the chair.—The meeting was called for the purpose of considering the report of a Committee appointed to examine the Chiswick School of Art, with respect to its suitability as headquarters for the Society in place of the Hall at Hammersmith. The Committee's report was adopted. A resolution to change the place of meeting forthwith was proposed by Mr. WHITCAR. An amendment to defer any change till the end of the present session was moved by Mr. LESLIE SELBY. The amendment was lost by 16 to 8. Mr. Whitcar's resolution was carried by 16 to 5. The Society will, therefore, in future, hold its meetings at Chiswick. The next meeting, however, on February 12, will be

held at Hammersmith. A resolution to hold social meetings was carried, details to be settled by the Council.

Putney Photographic Society.—January 30, Rev. L. Macdona in the chair.—Demonstration of the new film enlarging method—*Cresco Fylma*—of Messrs. Hill Brothers & Freeman, who, besides having on view numerous prints and opal enlargements, demonstrated practically the few manipulations necessary to produce the enlargement. The process, while working more readily with transparencies, is also most satisfactory in the case of negatives, the gradual growth of the film being very remarkable. Contrary to expectation, no particular care is necessary either in the transfer of the film, or in any of the subsequent operations. Mr. A. R. Dresser, being unfortunately invalided, had sent a written paper on *Hand Cameras* (second lecture of the series on "Photography"), which, having been read by the Chairman, a large number of enlargements from quarter-plate hand-camera negatives were handed round. These were mostly on Fry's "Roughest" (late "Naturalistic") bromide paper, and toned with uranium. Following these, some eighty slides were exhibited. A set of American slides, brought by Mr. A. Ovey, concluded the evening.

Richmond Camera Club.—January 29.—Mr. CEMBRANO (the President) gave some practical instruction in the *Manipulation of the Optical Lantern*. He spoke of the different illuminants—oil, gas, and electricity—describing the various lamps in general use, and the principles and details of the oxyhydrogen light with the blow-through and mixed jets. The various parts of the lantern were clearly explained, and the differences in detail to be found in the principal makes commented upon. Finally Mr. Cembrano, with the Club lantern, illustrated practically the process of centering and regulating the light and all other details of manipulation.

Bath Photographic Society.—January 27, Mr. W. Pumphrey, President, in the chair.—Messrs. E. J. Appleby and H. A. Wilkins were appointed auditors of the Treasurer's accounts. Mr. E. J. APPLEBY then spoke on the subject of rodinal, which he believed was a derivative of coal tar, a strongly alkaline solution of para-amidophenol. He had made a number of comparative tests, varying the percentage of dilution, as against pyrogallol methods. These were handed round for inspection, and showed rodinal to give less plucky negatives than pyrogallol. Mr. Appleby also drew attention to a number of transparent positives developed with the new agent; here excellence of quality was manifest. The members were invited to test rodinal and report their experience at the next meeting, samples being handed them for that purpose by Mr. Appleby. The HON. SECRETARY (Mr. Middleton Ashman) said his first trial of rodinal showed over-exposure, and subsequent tests pointed to the necessity of a restraining agent being present; then plucky negatives could be obtained. Its behaviour in the case of transparent positives left little to be desired—indeed, in the near future gelatine plates and rodinal developer would be the best method of making lantern slides. The CHAIRMAN spoke of some wonderful cloud effects he had recently seen in photographs produced by a new form of shutter, details of which were promised for the following meeting. Mr. JOHN DUGDALE exhibited a selection of lantern slides he had produced by the wet-collodion process, from negatives comprising views of the fleet and racing yachts, of Gibraltar, Malta, Siam, Switzerland, &c. These were shown by means of a Keevil prismatic lantern and self-registering carrier operated by Mr. Davis.

Liverpool Amateur Photographic Association.—January 28, Mr. Paul Lange in the chair.—Mr. LANGE thanked the members for the loyal support they had given him during the two years he had presided over the Society, and vacated the chair in favour of the new President (Mr. William Tomkinson), who had a very flattering reception. In the course of a short address, Mr. TOMKINSON expressed the hope that the Society would very soon be possessed of more commodious club-rooms, when it was his wish to give an "At home" to the members and their friends. He also expressed his intention of endeavouring to extend the work of the Association, particularly in the way of instruction for beginners, and of using every effort to make the Society as successful under his presidency as it had been under that of Mr. Lange, to whom he proposed a very hearty vote of thanks, which was carried with acclamation. The Chairman then introduced Mr. T. S. TAYLOR (Taylor, Taylor, & Hobson), of Leicester, who gave a lecture on *The Design and Use of Photographic Lenses*, illustrated by experiments and diagrams with the optical lantern. The lecturer afterwards gave full and lucid replies to questions asked by various members. In reply to Mr. Lange, he stated that no advantage beyond that of variety was secured by the employment of Jena glass in the manufacture of photographic lenses, although it was of some advantage in telescopic work.

Sheffield Camera Club.—January 27, Annual Meeting.—After the report, which was a satisfactory one, and showed an increase in membership, was read, the following officers were elected for the ensuing year:—*President:* Mr. G. E. Maleham.—*Vice-Presidents:* Messrs. Morton and Rawson; *Council:* Professor Arnold, Dr. E. Skinner, Messrs. Newsholme, Strangways, Copley, and Ellinor.—*Treasurer:* Mr. B. W. Winder.—*Secretary:* Mr. W. Gilley, jun.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

THE TELESCOPIC-PHOTOGRAPHIC LENS.

To the EDITOR.

SIR,—I, too, am content to leave the matter where it stands. I may, however, mention that the chief part of Dr. Schroeder's *résumé* refers to the "positive method" incorporated in the "photo-heliograph." Instruments of this form have been supplied by my firm many years ago to the Greenwich, Kew, and South Kensington Observatories, as well as to many other colonial and foreign-government observatories. Dr. Schroeder makes, with regard to the "negative method," reference to the employment of a negative lens, which I concur in believing to have been invented by Barlow. This, too, is in connexion with observatory work.

As the matter now savours too much of the nature of a "trade" discussion between myself and another firm of opticians, and Dr. Schroeder, the optician to that firm, I think with you, sir, that the matter had better be left "where it stands," as you say, in that this course will save both your space and my time, so that any further controversy, if necessary, can be settled in another place.

It remains only to state that the most recent works on the optics of photography have come from the pens of such men as Dr. Charles Fabre, M. Wallon, Dr. Eder, and Dr. Schroeder himself, and in none of these works is reference made to a photographic lens such as I have constructed.—I am, yours, &c., THOMAS R. DALLMEYER.

25, *Newman-street, London, W., February* 2, 1892.

FORENSIC IDENTIFICATION.

To the EDITOR.

SIR,—The other day I was looking through the back volumes of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC in search of Mr. Byrne's beautiful portrait of the Princess Victoria of Teck when I came across an article on "Forensic Identification," which, professing to treat the subject from a purely photographic standpoint, is obviously a thinly veiled endeavour to rehabilitate the exploded criminal imposture which, nearly a quarter of a century ago, sought to palm off a vulgar Wagga-Wagga butcher as an English baronet. Photography has rarely been prostituted to a baser use. On the "visual proof" of a couple of dodged "exemplars," in which the portrait of the real Sir Roger, who disappeared nearly forty years ago, is conjoined with that of the Claimant, taken at the time of the trial, with a result about as trustworthy as the photographic "Choice Blends" given in the first number of Mr. Jerome's new serial, the *Idler*, the man in the street, the final Court of Appeal nowadays, is left to find a verdict that the unhappy "nobleman" who languished on Dartmoor is the victim of "an absolute miscarriage of justice." The judicial decision in the case, we are told, was based on contradictory evidence. Most decisions in criminal cases are. If the evidence of rogues and detectives were always in agreement the administration of the law would be greatly simplified. The fact that the Claimant was ignorant of the name of his own mother is as naught against "anthropological admeasurements." You have only to get portraits of Smith and Jones, cut them in two, and "conjoin" half of Smith to half of Jones, and the jury's course is clear. If the anthropological admeasurements (whatever they may be) yield absolute identity, there you are. If not, you can easily solve the discrepancy by explaining that the nose of one of them had at some time been broken, and "the whole integument had shrunk." In a word, the "geometric" method of measuring compound noses is infallible. Smith may assert that he is Jones, or deny that he is Brown, but take a snap shot at Jones or Brown, conjoin half of the counterfeit presentment with a moiety of Smith's, take anthropological admeasurements, by placing the resulting print behind the wires of a birdcage, and you have evidence which outweighs any unfavourable conclusions depending on the accused's inability to remember the very last things a human being would be likely to forget. Thus, an impostor, claiming to have been educated at Stonyhurst College, when asked to look at a Greek grammar, may hold it, in sheer ignorance, upside down; he may live in sordid poverty in Australia, oblivious of his balance of thousands at Glyn's; being an English aristocrat he may have, on his return from the Antipodes, a burning curiosity to investigate the family affairs of the Ortons at Wapping; he may have lived a long time in Paris, quite familiar with the French language, and yet remember not a word of it some years later; and he may have been indelibly tattooed by two of his fellow-students at college, and yet be unable to show any trace of the operation when unexpectedly called upon to show the decorated arm. All these, and a host of other circumstances, all pointing to one conclusion, go for nothing with people who saw in the Claimant just the man fitted to become Member for Stoke; who were eager to believe in the innocence of Mr. Stead's hero, Lipski, and who were clear, two months ago, that the Hargreave jewels were certainly not stolen by Mrs. Osborne.

In this year's issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC we have "More about Identification by Photography," and from the same source. The writer, who, with comical unconsciousness, associates himself with that arch-impostor, Dr. Pangloss, A.S.S., gushes in gratitude to Fortune and to a country journalist, who seems to have taken him seriously. And he proceeds to strengthen and establish his position by further "disclosures." With the aid of a "recently devised identiscope" he has noted some peculiar markings on the Tichborne portraits. These markings, "artistic in type," are only "very dimly visible to unassisted

sight;" and, when pointed out to sympathetic personal friends, some saw, and others thought they saw, what was pointed out to them, while some, less discerning, saw nothing but the ordinary characteristics of a photograph. Even that "foremost friend" of the Claimant, Dr. Kenealy, could see nothing; Miss Kenealy "certainly saw what was pointed out to her;" Mr. G. Onslow, another devoted friend of the "incarcerated person," intervened with "Don't move any more in the mark on the nose." Again, "he who should best be cognisant of the matter knew nothing about it;" and then, we learn, "the whole question was consigned to the tomb of the Capulets." But the apologist of fraud, though "nearly reduced to a minority of one," is by no means content to leave it in that sepulchre. The monument of the Capulets, to him as to Romeo, is "Gorged with the dearest morsel of the earth," and, like Romeo, he applies the crowbar. He disinters the "diapered convolutes of needle-punctures," which Sir Roger knows nothing about, and which nobody else can see. In no wise discouraged, the modern Pangloss considers himself in "a position to sustain his primary allegation that there exists on the face of the Claimant the vestiges of a wrought-out design of some elegance." By next year we may hope that the identiscope will have identified fresh elegancies in a personage who, when I saw him in Westminster Hall, a score of years since, hardly appeared rich in personal fascination. Possibly, in the Almanac for 1893, a sly sense of humour may again offer the apologist "an open door," through which, dimly visible to unassisted sight, amused readers may discern that the Claimant, like Katisha in the *Mikado*, combines with a plain face "a left shoulder-blade that is a miracle of loveliness."—I am, yours, &c., T. H. W.

February 1, 1892.

RATIO OF GRADATION.

To the Editor.

Sir,—Under the above title, Mr. James R. Hopwood brings forward, in an article appearing in The British Journal of Photography of January 22, the contention of Messrs. Hurter & Driffield, that no developer, nor any alterations in the constituent parts of any developer, will effect an alteration in the ratio of gradation which can be developed in a plate which has had a certain exposure. Mr. Hopwood states, and no doubt states correctly, that this conclusion of Messrs. Hurter & Driffield "has so far remained a dead letter to the ordinary photographer, who consequently believes, and maintains, the exact contrary."

It is certainly strange that some of the many competent experimentalists in photography, who hold an opinion contrary to that of Messrs. Hurter & Driffield, should not have made and published the results of experiments to justify their view; but, beyond the expression of opinion at a meeting of one of the London societies last year, there appears to be very little to which an appeal can be made by the "ordinary photographer" as a reason for believing and maintaining the exact contrary to the statement that development cannot effect any variation in the "ratio of gradation."

Of that little, however, an example may be cited which, unless contradicted or explained away, would seem to be sufficiently good ground for holding to what has always been the accepted view of photographers in general, and one might add the usual experience of most people during development of a series of plates, especially if those plates have been exposed on landscape subjects. The example in question is a paper by Captain Abney, in the *Year-book of Photography* for 1880, page 127. Captain Abney there describes a method for developing plates which have been exposed on subjects having great contrasts, such, for instance, as a snow-mountain in sunshine, together with dark pine trees in the shade, and for the present purpose the important statement contained in that paper is that the author exposed two plates under practically identical conditions, for equal times, upon the same subject, and by applying different methods of development to each, obtained such a wide difference in the ratio of gradation that in the one case the mountain was almost lost in the sky, and the pine trees showed practically no detail; whereas in the other, not only did the mountain stand out from the sky, but even a fleecy cloud hanging to its side showed in the print, and also there was detail in the pine trees. Such being the facts, which are hardly likely to be disputed, and if they are, can very easily be verified, it is difficult to see how any explanation can make them square with Messrs. Hurter & Driffield's contention, for it is obviously futile to say that really the gradations are the same in both negatives, and that longer printing, or some other means, would make this apparent; and if, for the sake of argument (and for that only) it be admitted that in both negatives a scale of gradations, from, perhaps, clear glass to opacity, may be found, yet it is clear that the same objects in each will occupy very different relative positions in that scale.

Mutatis mutandis, this is the experience of most photographers, and as this striking dissimilarity in results has, for the most part, been made apparent to them by experience in out-of-door photography, though it may be unscientific, yet it may be useful to suggest that Messrs. Hurter & Driffield should, by experiment with negatives not exposed beneath a sensitometer, but to an ordinary landscape, see if, under those conditions, an alteration of the developer will not alter the ratio of gradation, or perhaps they may thus arrive at an explanation which may reconcile the two contentions.

Until lately it seemed possible that an explanation might be found in the phenomenon of reversal. For instance, it might be contended that in landscape photography the high lights were sometimes so much over-exposed that partial reversal had begun, and that such plates were alone susceptible of being altered in ratio of gradation by alterations of the developer; but recently it has been asserted by workers on the Continent that even with plates exposed beneath a sensitometer, under all the precautions to ensure equality of exposure which can be taken in a laboratory, a totally different scale of gradation may be obtained by applying to one plate an ordinary developer, and to a similarly exposed one a *very* dilute developer, and allowing it a longer time (more than an hour) to act. In the first case, the early numbers of a Warnerke's sensitometer were of almost equal blackness, that is to say, the steps in the scale of gradation at that end were abrupt, whereas, in the latter case, the scale of gradation was much more regular, this being especially apparent in the squares of the early numbers.

Of course this experiment with plates exposed beneath a sensitometer gives results directly contrary to those arrived at by Messrs. Hurter & Driffield; but, on the other hand, the result is exactly analagous to that which Captain Abney has put on record in the paper cited above, and it is only what one would have expected, for the methods of development were also analogous.—I am, yours, &c., M. J. Michael.

Davos Platz, St. Moritz, January 25, 1892.

URANIUM TONING, ETC.

To the Editor.

Sir,—For several years past I have used uranium for intensifying negatives, and also toning lantern slides. Some negatives done in this way eleven years ago are as good as ever, which, I think, is a fair proof of permanency. I have recently tried the newer formula, using acid; in the old method no acid was used. I find that, using acid, the plates become a green colour, which renders them useless for lantern slides. This, I find, disappears if a hypo bath is used after toning, but then the slides become a red of a most objectionable tint; this is the same whether the hypo be acid or not. Soda or potash removes it, but not until the proper red tone is gone as well.

Now, the acid, however, has one great advantage, and that is, that the slides tone more evenly than without it, and there is better control of the colour. Is this green colour inseparable from the acid solution when used for plates? It does not seem to come with bromide paper. One word more on another subject. Some of the few slides I have, on gelatino-chloride plates, have nearly faded away; others, made at the same time and treated in exactly the same way, are all right. I do not think this looks promising for chloride paper, which is coming so much into use.—I am, yours, &c., H. G. M. Contbeark.

The Hut, Ingatestone, January 28, 1892.

MIDLAND COUNTIES POSTAL PHOTOGRAPHIC SOCIETY.

To the Editor.

Sir,—I write to strongly support Mr. Bankart's scheme for the formation of a *Midland Counties Postal Photographic Society*. I have long been privileged to see and to admire the magnificent work done by Mr. Bankart, and I have profited not less from his criticisms upon my own work and that of others, than from his own photographs and descriptions of his own methods. With Mr. Bankart as the moving spirit the success of the proposed Society is assured.

I write now mainly to urge every earnest amateur in the Midlands to send his name and address to Mr. Bankart (West Walk, Leicester), in order that the Society may at once be established.—I am, yours, &c.,

W. Jerome Harrison.

Science Laboratory, Icknield-street, Birmingham, January 29, 1892.

A PLEA FOR FAIR PRICES.

To the Editor.

Sir,—Will you permit me to inform your very able correspondent, C. Ernest Barnes (January 8, page 2), that this Association of professional photographers has been specially formed for the purpose (among others) of dealing in a practical and business fashion with the evils and abuses of which he complains (price-cutting, enlarging for private persons at trade prices, &c., and other existing anomalies)?

I respectfully doubt if any "*syndicate of photographers*" could, as he suggests, deal so effectually with the malpractices of the trade as an Association like ours, provided it receives what is absolutely necessary for its efficient working, viz., a large measure of support in names and subscriptions from the profession which is to be benefited thereby. I shall be glad to receive the names of new members as soon as possible.

The annual meeting will be held at Anderton's Hotel, Fleet-street, London, Thursday, February 11, 1892, at half-past seven p.m., when *all*

professional photographers, whether members or not, will be heartily welcomed by the Council.—I am, yours, &c., D. J. O'NEILL,
Secretary, National Association of Professional Photographers of Great Britain and Ireland.
47, *Charlotte-road, Birmingham.*

"HAS PHOTOGRAPHY BENEFITED ARTISTS?"

To the EDITOR.

SIR,—There has been some rather lame argument upon the subject of art and its application to photography, but your correspondent of January 8, in the latter half of his letter, actually cuts off the sound supports of his argument, and substitutes crutches—very wooden one. It cannot be urged that photographers forget the credit due to the makers of plates, lenses, &c. Let any trade catalogue be examined, and in the majority of instances it will be found that Mr. So-and-So acknowledges lenses, cameras, plates, paper, or some other manufacture in the production of an exhibition picture. But, supposing this to be insufficient, let us give the argument another application. Let us ask to see something after the following attached to pictures in the Academy:—"Mr. Pallette wishes to acknowledge the great assistance rendered by the following gentlemen in the production of his picture. He has to thank Messrs. Wedg & Fraam for the canvas, the texture of this beautiful fabric giving an appearance of detail so much admired. To Mr. Pigments he is indebted for excellent colours, medium, varnish, &c.; and to Messrs. Hogsare & Cammile for their splendid brushes and pencils. He is furthermore *partly* indebted to Nature for his ideas." This, however, cannot be the end, for we shall want to see an acknowledgment to a modern master in conjunction with several old masters for the education and cultivation of style, and shall probably finish by insisting upon an acknowledgment of the intelligence, and right to exist, that allows an artist to be educated, or allows him to *be*.

Most art writers of any account emphasise the desirability of humility in the study of nature and art. Your correspondent evidently recognises the principle, without its personal application, for, while quarrelling with photographers for calling themselves artists, he calmly signs himself, "Artist with Brush, Pencil, and *Camera*." "What's in a name?" Does your correspondent know of none who base their claim to be called artists upon an ability to daub? And does he, like the majority of artists, wish us to accompany him down into the slums, that he may point with the finger at our lowest representative, and say, with withering scorn, "And you call this art?"

If *sight* can come under the heading of brain power, there must be a little exerted in producing an instantaneous study (unless "study" means an accidental result); and, if practical men may be believed, there is even a little credit due to the successful posing of actors and actresses.

Truly there is little or nothing to prevent a painter making use of photography. A few mechanical difficulties, perhaps—mere nothings. Photography is already supposed to yield the best results in the hands of an artist (be he painter or photographer), so there was really no necessity for the question upon this point; but, surely, if there be any question as to the monopoly of the credit of photography, it must fall to the photographer. Who else? Who but the photographer has brought photography to its present stage, and who but he shall carry it beyond? As far as the *art* side is concerned, we *may* have something to thank the painter for (especially if he be sufficiently muddled to claim the ownership of first principles), but we thank him only for what he himself has borrowed.—I am, yours, &c., H. COLEBROOK.
Plumstead, S.E.

To the EDITOR.

SIR,—In your correspondence column recently, "An Artist with Brush, Pencil, and Camera," reverts to the much-vexed question, "Has Photography benefited Artists?" I have written two or three times to your journal with the intention of showing that it has; others have done the same, and one might think the matter settled by this time; but it will never be allowed to rest as long as people allow themselves to be swayed by prejudice and envy instead of reason. Though myself an artist, I must confess that most of the bigotry and uncharitableness comes from our side; my experience of photographers is not that they are humptious and claim too much for their profession, but rather the reverse. Your correspondent thinks the time is not far distant when photographers will have to qualify themselves as artists, or "take a back seat." I tell him that the time has arrived; for the front seats are occupied by men who are fully competent, not only in taste, but also in technical art education, and even ability with the brush and pencil. Why do "artists" display such snobbism as to pretend to ignore this fact? These men are more than fully qualified to practise art—photography they know as much about the school of art subjects as many artists themselves, although such knowledge is less indispensable to them. The humorous touch in the hypothetical advertisement for a clever operator, where, among other duties, he is supposed to "nurse the baby and wash the pots," &c., may be laughable, but it is extremely far-fetched; in fact, I felt sure anything of the sort never was demanded of any operator. It seems to me a piece of high-handed superciliousness to suggest it. Artists are not cheap, but photography has done much to bring a great deal of artistic enjoyment within the reach of the multitude. Certainly artists are at liberty to practise photography, in fact they do so, both openly and surreptitiously, though with less concealment than formerly. I knew an artist some twenty years ago, who found it "did not pay" to be associated in business with a photographer; so the partnership was dissolved, and this was because his paintings were regarded with the suspicion that they owed something to photography, which they did not, for he was positively afraid of employing it. Nowadays one sees many pictures in exhibitions which are unmistakably copied from photographs, and why not? Art is long, and a short cut is a desideratum: no fear of getting too soon to the end of the road.

The difference between the two paths is this: In painting, a man can call himself an artist as soon as he can make a passable image of something; but in photography his hardihood would be a theme for mockery if he pretended to be an artist on such simple grounds. A ten-and-six-penny camera might enable the most inexperienced boy to produce a picture which, in point of correctness of drawing, would beat the embryo painter's work into a cocked hat; but would the boy therefore seriously claim the title of "artist?" It is unnecessary for me, in this letter, to recommence the definition of the words "art" and "artist;" it has been done most exhaustively in your pages. Artists, in the best and truest sense, are necessarily always rare, but there is a class just below that which is very popular and useful, and quite able to hold its own against the sneers of the envious. Of the first class there are scarcely half-a-dozen in a century; the second comprises all them that are able to produce pictures that please, even though they do not greatly elevate the mind, and there are many photographers that may be included therein. As to the relative difficulty of the work, what does that matter? We admire some works for the cleverness displayed in their execution, and others for their beauty and interest, without thinking much about how they were done; and this is generally the case in respect to the very highest art—our minds are too much occupied with the æsthetic and intellectual emotion afforded to let us even wish to poke our noses behind the scenes; and this pleasure, we feel, is not merely due to the perception of a display of "model, free-hand, geometry, and perspective," nay, nor even of anatomy. These are but the apparel, the "trappings and the suits" of art, which may exist in many mediums, not excepting photography.

Your correspondent asks if there is any credit in getting a good pose of a clever actor or actress, by which he implies that he or she supplies the pose, that is a help; but it requires the artist's eye to select a good view of that pose and to determine what proportion the figure shall bear to the picture, and whereabouts it shall be placed. I am not called upon to speak further about the lighting of it, or composing it together with other figures or accessories. What I deplore is the grudging way in which some artists regard the works of photographers, and their affected superiority. Why, I have known photographers who could draw and paint extremely well, and would have been welcomed in artistic circles, but that the profession of photography disqualified them. It is a pity that painters, who could afford to be magnanimous, should show such littleness and spite. I never heard a photographer speak of painting without admiration and respect, and the hostility I have observed comes from the other side; but I suspect it is from neither the first nor the second class of which I have spoken, but from the mere camp followers, the skirts and rabble of the army—persons who can only make crude images of things and fail altogether to breathe into them the fire of expression, whose best performances are inferior to the most mechanically evolved photograph, and infinitely inferior to one that contains sentiment, thought, or story.—I am, yours, &c., F. WILCOCKSON.
London, January, 1892.

IMPRESSIONISTIC PHOTOGRAPHY.

To the EDITOR.

SIR,—Will you allow me, as a working painter (painter-artist, I ought perhaps to say), occasional photographer, and constant reader of your valuable paper, to thank you for the pleasure and amusement the article signed "A. R. S." in your last issue has given me.

I take up your paper, as a rule, for the purpose of studying serious and scientific articles, never expecting to find anything of a humorous nature in your columns. I have been, however, agreeably disappointed. I allude to "A. R. S.'s" letter. It is unnecessary to take this letter *seriatim*.

Is every other line meant to be a joke, or is it, do you think, only by accident that there is that appearance? Why is the writer so hard on the poor photographer? and why is the poor student required to watch a "suitable landscape" for a "few months?" why should the photographer leave off his business to learn that of the etcher and the water-colour painter? and why should the poor student, after studying his "six months" efforts, be required to kick his camera—his "lying camera," forsooth, to the zenith, wherever that may be—and then go a-stone breaking, or learn golf? Why all these things? and are they appropriate to a paper exclusively devoted to photography?

The writer of this article, Mr. A. R. S., somehow reminds me of a certain other writer who, once upon a time, being desirous of learning something of a certain subject, wrote a book thereon, and afterwards, having learnt something about his subject somewhat publicly, withdrew his work; but, then, though the principles of that work were, to say the least, quaint, the grammar was passable. Thus your correspondent, being also possibly anxious to learn and to know, endeavours to attain his ends by abusing everything that he knows little of, and laying down the law about what he knows less of, so that the information given to him in the form of correction may be useful at other times as the basis of more humorous letters; but why; oh, why, does "A. R. S." use the expression, "thus showing how the fool is ever discovering himself for the benefit of the multitude?"—I am, yours, &c.,

London, February 1, 1892. ONE OF THE MULTITUDE.

ARTISTS AND PHOTOGRAPHY.

To the EDITOR.

SIR,—I was glad to read your all too brief "Art Notes" of January 29, as it seemed to me, as a very humble student of photography in relation to art, that those notes contained one or two home truths, the contemplation of which cannot but have the most salutary effects upon photographers and artists alike.

You instance some of the frames in the late Pall Mall Exhibition as eliciting universal condemnation. True, sir, they did; and such condemnation I hope as will prevent the admission of such monstrosities in future. The only gleam of comfort in that miserable business is that (*vide* the Civic frame to the portrait of Kaiser Wilhelm) photographers are not the only sinners in this respect.

Mr. C. P. Sainton, if he reads the JOURNAL (which I believe he does), will find it difficult to answer your question. This gentleman is a friend and pupil of Mr. Mortimer Menpes, whom your contributor, "A. R. S.," tells us uses photography as a basis for art. True for you, "A. R. S." "Charlatan and impostor" are the only words which correctly apply to such practices.

Go on, Mr. Editor; "picture-frame making," "charlatanry," and "imposture" are rife in the world of photography as well as in that of "art," and I hope you will continue your "Notes," and let in a little light upon these dark places.—I am, yours, &c., CHARLES BROWN, JUN.

Theydon Bois, Essex, February 1, 1892.

P.S.—I think I can guess who "A. R. S." really is; "the voice is the voice of Jacob," &c.

CAMERA CLUB CONFERENCE.

To the EDITOR.

SIR,—Will you kindly announce that the annual conference organized by the Camera Club will take place at the Society of Arts under the presidency of Captain Abney during the last week of March next? The arrangements of former years will be slightly extended so as to secure an evening meeting in addition to the day meetings for the reading of papers.

The exact dates and outline of the arrangements are as follows: Monday, March 21, 8 p.m., Smoking concert, and the opening of the Members' Annual Exhibition of Photographs at the Club. Tuesday, March 23, 3 p.m. Opening of the Conference by the President. Papers will be read and discussed until 6 p.m. At 8 p.m. the Conference will again assemble and sit till 10 p.m. Wednesday, March 23, Conference from 3 to 6 p.m. Annual dinner at 7.30 p.m., Thursday, March 24, 8 p.m. Special lantern exhibition at the Society of Arts for members and friends.—I am, yours, &c., G. DAVISON, *Hon. Sec.*

Camera Club, Charing Cross-road, W.C.

DINNER OF THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

To the EDITOR.

SIR,—Permit me to remind the members of the above Society and their friends who wish to be present at the dinner (on Monday, February 8), that immediate application should be made for tickets to myself, or the Assistant Secretary, 50, Great Russell-street, W.C.—I am, yours, &c.,

W. ENGLAND.

7, St. James's-square, Notting Hill, W., February 3, 1892.

WATER AND FILTERS.

To the EDITOR.

SIR,—Since penning the few lines to you about "Tylar's Filters," I have had a very interesting experience about the purity of filtered water. I have been residing for the last fortnight at a Hampshire watering-place, famed for its mild climate and pure water. I noticed that the water supplied at the table savoured of rain. This led me to inquire if the house had a rain-water tank. The reply was no, and that all the water supplied at table was carefully filtered. I was induced to test the filtered and unfiltered samples; the result was very much in favour of the *unfiltered*. Another proof of the theory I have long held that to filter the water as supplied by the various companies is a "snare and a delusion" to do so, means that one filters good water through a mass of impurities.

I am pleased for Mr. Tylar's compliment; I cannot have "carped" at the price, for the simple reason that I do not know Mr. Tylar's price; but I would like to know where the novelty or improvement comes in. Mr. Tylar evidently does not know that some months since I exhibited the filter at the London and Provincial Photographic Association, and I then stated its disadvantages.—Yours, &c., A. L. HENDERSON.

"*The Paragon*," *Bournemouth.*

LOSS OF DENSITY IN FIXING.

To the EDITOR.

SIR,—A great many things have been asked lately from the dry-plate manufacturers, such as backing, marking, &c., all of which involve trouble, time, and expense, and it would be cruel to add something more to those more or less just demands. What I would ask from them is much easier to obtain, and would certainly be to their own good as well as to their would-be customers, if not the old ones. It is simply a printed line on the label, and the directions, something like this: "The plates *do not lose much* (or *lose rather much*) during fixing in the hypo."

I have never found a plate being any worse because it loses more in the hypo (of its intensity) than another that loses less, provided I knew it before developing. All I had to do was to develop a little longer, and everything was right. A little over-developing does not matter; the negative is a little harder to print, which is not a defect. But suppose one does not know, and develops a new brand of plates, and finds that in the hypo almost all melts away, and he has a thin negative, no good to print from. Look at the trouble of intensifying, &c., if it brings out anything decent. I am of the opinion that a good many so-called under-exposed pictures are simply not enough developed to suit the extra loss in hypo, and certainly a somewhat under-exposed negative will lose much more in the hypo than a fully exposed one, the same as a print on albumen paper from a hard negative has to be printed much deeper to counterbalance loss of intensity in gold and hypo baths. Now, if we should know that a plate loses more or less in the hypo, we could develop accordingly, and save a great many negatives, and not always blame for it the manufacturer and the exposure.

I have been trying lately some different plates, and found them very very much to loss of strength in hypo, and so much so as to be worthless, however fully developed, as compared with my regular run of plates. When a friend asks me to develop a plate for him, my only question is, "Does your plate lose much in the hypo?" If you do not know of this, try it once upon two different plates (manufacturers), and you will see for yourself, pushing both to the same density first, and from instantaneous exposures, both to make things even and sure.—I am, yours, &c., ALBERT LEVY.

Asnières, France, January 26, 1892.

PREVENTION OF BLISTERS.

To the EDITOR.

SIR,—I notice there are a great many bits of information and experiments given for the prevention of blisters occurring with albumenised papers. At the beginning of the winter I commenced using albumen paper (the first time for many years) and the first batch I did was nearly ruined by the paper blistering. Some years ago the same thing occurred, and I then tried if I could not get rid of what I looked upon as a great nuisance. I succeeded, and am now doing as I did then, and I am not troubled with blisters. If any of your readers will try the following, I do not think they will be troubled again. Printing, washing, and toning is carried on as usual up to the fixing, and then I make a bath-hypo, one to eight, and for one gallon of this I add two ounces methylated spirits and two drachms ammonia, ·880.—I am, yours, &c.,

Redcar, January 25, 1892. R. J. BURNS.

Exchange Column.

**** No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR,' 2, *York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

**** Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," 2, *York-street, Covent Garden, London.*

LLIAN.—Apply to the Autotype Company.

CYMRY.—Acetic acid is a solvent of gelatine.

A. H. B.—Presumably after the prints are washed.

LENS.—It is a single landscape lens of the ordinary type.

A. H. S. B.—The method you propose is the best for the purpose.

A. C. T.—You will find the formulæ of all the plate-makers collated in the current ALMANAC.

RIPON.—We had a series of articles on photographic enamels in our last volume, to which we refer you.

RUDOLPH LEONHARDT.—1. We fear there is no remedy. 2. Thin sheets of gelatine would answer the purpose.

R. M. C.—1. *The History of Photography*, by W. Jerome Harrison. 2. We cannot trace the article under that title.

NOVICE (Henley).—Messrs. Thevoz' pictures are, we believe, done by the collotype process, on specially chosen papers.

H. HERBERT.—If the plates give too much density with the developer recommended by the makers, reduce the proportion of pyrogallic acid.

R. C. T.—If the picture is copyright, it is illegal to copy it, even if the copies are not sold. You seem to be labouring under a misapprehension.

W. R. KENNAN.—If you refer to Suiter's gauges, we do not know the address of the manufacturers, but the gauge may be obtained of any dealer in lantern requisites.

C. H.—The photographs would have been better if they were more plucky; but we have seen many by professional photographers which were inferior to those sent.

WILLIAM CHAPMAN.—The patent is, we believe, still in force, but you had better consult a patent agent as to the possible risks of infringement involved in your improvements.

AG_2 BR.—The reason for your developer working slowly of late is undoubtedly due to the fact that the solutions were at too low a temperature. All chemical action is retarded by cold.

B. J. BARCLAY.—If the ready-sensitised paper shows minute spots before it is printed, and they become larger and metallic when toned, there is no way of avoiding them in the finished pictures, except by using a different paper.

C. J. KIRK and F. C. BEACHAM.—There is no directory of photographers published, but the *Chemical Directory* (published by Kelly & Co., Great Queen-street, W.C.) gives a list of all the photographers in the United Kingdom.

CAMBS.—1. Swan's patent for carbon printing was taken early in the year 1864. 2. The patent has long since expired. 3. No licence whatever required. 4. We are not aware if a fresh edition is likely to be published shortly.

C. W.—We are unable to inform you if the saying, "Something has gone wrong with the works," originated with the automatic photograph machines. Is your query intended, as the late Artemus Ward would say, to be "sarkistic?"

THOMAS A. ROGERS.—Pinhole photography forms the subject of several short articles in the JOURNAL during the last few years, which may be found on reference to the various indices. We are not aware of any separate publication devoted to it.

R. WOOD.—Your friend was partly right and partly wrong. The platinic salts are, undoubtedly, sensitive to—that is, decomposed by—light, but the change is not visible in the cold-bath process, or any other platinum process. It is the persalt of iron which is acted on.

A. VOSS.—In working the wet-collodion process, a ruby light is not at all necessary. A couple of thicknesses of orange "tammy," over a window facing north, will be all that is requisite. Two thicknesses of canary medium, or possibly one, might suffice under similar conditions.

EXPERIMENTALIST.—There is no difficulty in coating plates with gelatine emulsion without a "proper machine." All the early plates were coated by hand. Indeed, some makers, we believe, do so still. A little practice is all that is required to obtain an even coating, and that is soon acquired.

CAPTAIN HEMMING, R.E.—The aniline process of Willis will answer your purpose. Full details will be found in our JOURNAL of 1865, or in the volumes about that date. J. R. Gotz supplies paper which will serve the same purpose. "Ink photos" are printed from a grained lithographic stone.

BOSTO.—If an image the same size as the original cannot be obtained sharp in the camera, it is clear that it does not expand sufficiently. Are you aware that, to obtain a picture of the same dimensions as the original, the camera must be distended to twice the focal length of the lens, whatever that may be?

S. A. W.—1. A lens of the "rapid" type will be the most useful for your work. 2. If a wide-angle lens of the same focus as a "rapid" be used on the same-size plate, the angle included will be the same. 3. The wide-angle will cover the plate best when used with a medium stop. 4. We have not heard the rumour.

X. X.—We have had no experience with vessels coated with Aspinal'a Enamel for gold toning solutions; we much prefer to use glass or earthenware dishes in our own practice, and recommend you to do the same. A few days' use will, however, prove if the enamel has any injurious action on the solution. You might give it a trial.

W. ABBOTT.—The maker of the lens, whoever he may be, has attempted more than he could accomplish—that is, if he did attempt it. A lens of four inches in diameter, and five and a half inches focus, to take a full-length cabinet portrait with the open aperture, is more than an English optician would attempt. Such a lens, if it would do that, would be necessarily very rapid.

A. FRASER.—A great deal of success in Woodburytype printing depends upon the paper used. After preparation, it requires very heavy rolling between highly polished plates, and this necessitates expensive appliances. We are not aware that the paper, ready for use, is an article of commerce in this country, though, we believe, it is in Germany. You might, however, communicate with the firms who work Woodburytype; they may supply it, for aught we know.

A. W.—You are quite right in your surmise. The dryer carbon tissue is made after sensitising, the longer it will keep. Indeed, if it be thoroughly desiccated, and kept so, it will remain soluble for months. But its moisture must be restored before it can be printed upon, and the difficulty in the way is to introduce the proper proportion—neither more nor less. Upon the right hygroscopic conditions of the tissue depends, in great measure, success, or otherwise, in carbon printing.

D. ASHBEY says he recently applied to three prominent photographers to take negatives of his sisters, and hand them to him, he being an amateur, and could make the prints himself. He asks if this is the custom with first-class photographers, and adds "that, if it is so, it is very unfair, as no one wishes to pay a large price for what they can do quite as well themselves, at a trifling cost."—Of course, every one can arrange his own terms for business, photographers amongst others, and we believe the custom is as our correspondent suggests. It is hardly to be expected that an artist will expend his time and skill to secure first-class negatives, and then hand them over to the sitter to get printed elsewhere, perhaps very indifferently. It is to the prints that the artist looks for remuneration, not from taking the negative.

H. B. A. says he has a plot of ground large enough for building a studio twenty-two feet by twelve and a half feet, facing north, and asks how to build to, without using stone, so as to obtain first-class portraits therein? As a north aspect can be obtained, we should advise the roof to be on the "lean-to" principle, and glazed about two-thirds its height, or up to about thirteen feet. Each end sides and roof, for about feet six inches, should be made of opaque material. The structure may be of wood, and such as a horticultural builder would construct. Twelve or fifteen inches will be wide enough for the panes of glass. Twenty-two feet is rather short for a studio where "first-class" results are desired, as it will necessitate the use of short-focus lenses when full-length figures or groups are required. In such cases short-focus lenses are not consistent with first-class pictures.

PHOTOGRAPHIC CLUB.—February 10, *Glass Blowing for the Laboratory*, Mr. A. Haddon. 17, *Public Exhibitions*, F. P. Cembrano, jun.

LOW PRICE OF SILVER.—On Tuesday last bar silver fell to 41⅞, at which figure it was bought for India. It is stated that this is the lowest price on record. On the same day Mexican dollars fell to 40¼.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—February 8, Annual Dinner, at Café Royal, Regent-street, at half-past six p.m. February 9, Annual General Meeting, at eight p.m. February 23, Technical Meeting, *The Relative Merits of Different Processes for the Production of Lantern Slides.*

THE ANTIPHOTON.—From Messrs. A. R. Wormald & Co., of Sutton, Surrey, we have received the Antiphoton, which, when fixed in the wall of the dark room, permits a free passage of air from outside, while it excludes daylight. It is of thin metal, and its uses will indicate its construction. For the purposes assigned it should prove efficient.

NORTH LONDON SOCIETY'S FIXTURES.—February 16 (Technical), *Uranium Toning*, Mr. J. Weir Brown. March 1, *Platinotype Printing*, Mr. J. Martin. March 15, Lantern slide competition. April 5, Technical Meeting (Apparatus, &c.). April 19, Exhibition of Lantern Slides. May 3, *Light Measurement*, Mr. W. Bishop. May 17, Mr. J. Traill Taylor. June 7, *Retouching*, Mr. Redmond Barrett.

ROCHDALE AND DISTRICT PHOTOGRAPHIC SOCIETY.—The Exhibition of the above was brought to a close on Saturday, January 30, after a very successful run. The Lantern Evenings from members' slides were a great attraction. On Tuesday evening a *Conversazione* and Musical Entertainment was given, consisting of lantern exhibitions, songs, and recitals. Mr. Harry Fletcher had the sole charge of the lantern.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1658. Vol. XXXIX.—FEBRUARY 12, 1892.

A PHOTOGRAPHIC INSTITUTE.

During the session of the Photographic Society of Great Britain that has just closed, three papers were read which have a close bearing upon a matter which so many members of the Society, and others, have at heart, namely, the establishment of a central institution affording instruction by qualified professors in the higher technology of photography. No definitive scheme has to our knowledge yet been put forth; but, so far as we can assimilate all that has been written and said on the subject, the general aim is to provide facilities for the prosecution of experimental work and the study of particular branches of applied photography, the theory and the practice being placed equally at command of the student, so that both intending professors and practical experts might have the advantage of deriving their knowledge from a properly constituted and efficiently equipped teaching centre.

Taken in the order in which they were read the three papers we have referred to constitute an admirable introduction to a study of the whole question. Mr. Warnerke's description of the photo-technical schools in Belgium, Germany, Austria, and Russia lays before us in a succinct form the facilities which exist in the capitals of those countries for the acquirement of a theoretical and practical knowledge of photographic technology. The establishments are under Government control, and are presided over by such men as Vogel and Eder. The fees are moderate, and, especially in the Berlin and Vienna Institutes, the courses of studies are arranged upon a scale of completeness which it would be difficult to excel. We have no doubt that in any scheme for a photographic institute which may afterwards take shape in this country, the particulars which Mr. Warnerke has gathered together will be of the greatest utility in forming a guide to the needs of such an establishment. The second paper to which we are alluding was contributed by Mr. Bolas. In it he pleaded for facilities for experimental work, to such as might wish to do it, in the view of establishing general principles, and the establishment of regular courses of instruction by competent teachers. The third paper, by Professor Meldola, after pointing out the value which photography has been found to have in modern scientific work, concerns itself with the claims of photography to be placed on the same basis as other branches of technology, and goes on to argue in favour of an institute dispensing technological instruction.

We are happy to see that the Professor ignores the trite advice which is usually given at the outset of any educational scheme, namely, to apply to the public treasury for help. The hope that Parliament would vouchsafe assistance in the matter would not be worth entertaining. His suggestions are of a far more practical nature. He points out that the staff of the institute need not be numerous at first; a chemist, an optician, a physicist, an expert in photo-mechanical processes, and an artist would represent the chief departments, and he proposes a conference of all photographic societies, with the object of forming a joint committee, under whose authority a further appeal might be made for public and private support. He furthermore points out that, as elementary photography is being taught all over the country, a few first-class specialists might be enlisted to give short courses or demonstrations to those affiliated societies or centres which desired such instruction.

This, as we have said, is practical advice, the soundness of which we hasten to recognise. Professor Meldola's lecture, as our readers will see, is a very long one, and its interest is in proportion to its length. It contains matter for serious and careful reflection, to which on the present occasion we can do no more than make but brief reference. We join with him in the hope that any action taken by the Society will be of the highest possible character. The institute will need to take a somewhat lofty aim. The higher specialisation to which such a body should devote itself must be supplementary to the elementary instruction which is now being so extensively disseminated. It is this higher specialisation which, as the Professor effectively maintains, is in some danger of neglect just now. A photographic institute, therefore, should do more than impart a mere elementary knowledge of principles and practice to the student; it should take the latter in hand when he has mastered the groundwork of his subject, and give him the opportunity of acquiring that deep and intimate knowledge of it—in short, make a well-trained specialist of him—which alone can fit him to hold his own against his foreign competitors in modern photographic progress.

To the idea of a technological institute, so ably outlined and pleaded for by Messrs. Warnerke, Bolas, and Professor Meldola, we give our heartiest support, in the hope of seeing it realised, and the desire to assist in its accomplishment. It needs no very intimate acquaintance with the internal economy of English manufactures at this time to be aware that the demand for thoroughly competent technologists—men skilled in the theoretical and practical principles of optical and chemical preparations—are just now far from being at a discount, while the possibilities open to them in the larger worlds of science, the arts, and the manufactures are very great. In course of time, when competition becomes keener, as it inevitably must, and the power of knowledge will be the one power above all others that will make itself felt, the success or failure of photographic manufactures will be determined by the skill or incompetency of those by whom they will be conducted; and a technological institute that provides facilities for the acquirement of such knowledge will be a valuable factor in assisting this country to maintain its pride of place in the world of photography.

In the Continental institutes, of which we have spoken above, the study of photo-mechanical printing processes is an object of special attention. It is a matter of common notoriety that in this department of photography we, in this country, are, in far too many respects, not equal to our neighbours. Instruction in this field, as was pointed out in the course of the short discussion which followed Professor Meldola's lecture, is difficult, if not impossible, to obtain, except, of course, under payment of very high sums of money, so that here the institute may at once step in and supply a long-felt want with incalculable advantage. If, in addition to purely technological matters, such as the study and application of chemical principles, optics, and process work, conjoined to the innumerable subdivisions into which the production of photographs is split up, studio work generally, embracing lighting and posing, were included, the ordinary run of portrait photographers, as a body, would not improbably derive considerable benefits from the scheme.

We do not, however, gather that this forms part of the aspirations of those who have the foundation of such an institute at heart, although, if example be taken from the Continent, work in the studio could not be neglected. As to the "artist" whom Professor Meldola would give charge of a department, we fear that here the only debatable part of the scheme is touched. It would be wise, for the present at any rate, to eliminate this section from any plan, inchoate or experimental, until there was a more common agreement among the photographic public as to the meaning and application of "art" in relation to photography. Just now, every one has his own pet idea on the subject. We could easily select professors or teachers of photographic chemistry, of photographic printing, and the like; but, of recognised teachers of "art" in this connexion, there is no plethora, and therefore we hope the scheme will fight shy of including art teaching in its curriculum.

For the rest, we congratulate photographers that, at a moment when the cry for technical education is rising up from every branch of the community, their own special needs are enlisting attention, and in after-years we hope to have the pleasure of feeling that the three papers of which we have made mention constituted the starting-point of a successful scheme of photo-technological instruction.

ANALOGY OF GELATINO-BROMIDE OF SILVER TO BICHROMATED GELATINE.

Every one is now pretty familiar with the fact that bichromatised gelatine becomes insoluble in warm water when it is exposed to light. It is not our purpose in the present article to treat upon the action of hot water on bichromated gelatine, but to point out other characteristics of the material—more particularly its expansion or "swelling" properties when treated with cold water; also to call attention to the circumstance that the properties of a bichromated gelatine film are largely possessed by a gelatino-bromide one, under certain conditions.

When a gelatine film sensitised with bichromate of potash is exposed to light under a negative, and is afterwards soaked in cold water, the water is absorbed in proportion as the negative has more or less protected it from the light's action. On this property is based photo-lithography, collotype, and other analogous processes. At the same time that the water is absorbed the gelatine swells up. This may be well exemplified by placing an undeveloped print on carbon tissue in cold water for a quarter of an hour or so, and then blotting it off. The image will then be found in strong relief, and with those portions that would have been dissolved away had the picture been developed with hot water in the highest relief, while those upon which the hot water would have the least effect in the lowest. On this principle are based those methods of making photo-mechanical printing matrices known as the swelled gelatine processes.

By the latter processes a much higher relief—or *intaglio*—can be obtained than that resulting from dissolving away the unaltered portions with warm water. We have now before us a porcelain *plaque*, moulded from a cast taken from a swelled gelatine relief, in which some portions are raised fully the twenty-fourth of an inch. Although by this method a very high relief is obtained while the gelatine is moist, a cast taken from it will not be so sharp and crisp as one taken from a washed-out relief, such as those made for the Woodburytype process.

The property of gelatine being modified by the action of light is not confined to its being treated with the bichromates, because analogous effects, both as regards swelling and insolubility, can be obtained, under certain conditions, with gelatino-bromide films, though the fact does not appear to be very generally known.

About a dozen years ago Mr. J. W. Swan devised and patented a method of producing printing plates by taking advantage of the above property. The process is this:—An ordinary gelatino-bromide plate is exposed in the camera, and, if a half-tone typographic block is desired, the exposure is made through lined screens in the usual manner. The image is then developed in the ordinary way with pyrogallic acid. After development the plate is subjected to heat, which causes those portions upon which the light has not acted, or only partially acted, to swell up the same as in the case of a bichromated film. Two methods of applying the heat are described. One is to place the plate in water at about ninety degrees; the other to heat the plate while the film is in a more or less moist condition. In his specification Mr. Swan refers to the effect that the alums, tannin, &c., have on the film in modifying the degree and character of the relief.

From the gelatine relief, obtained as above, the printing plates are made, either by taking a wax or other cast and from that an electrotype, or an electrotype is made direct from the gelatine film. By this method printing blocks can be produced in a very short time. The process has, not until recently, so far as we are aware, been made use of commercially. It may have been, however, without our knowledge, inasmuch as those who produce photo-mechanical plates do not publish the methods they employ.

About ten years back, Mr. Leon Warnerke published, and patented, a process based upon the principle that a gelatino-bromide film, developed with pyrogallic acid, becomes insoluble by the action of light in the same manner as does a bichromated one. Mr. Warnerke spread the emulsion on paper, and, after exposure, the image was brought out with the ordinary pyro developer. The picture was then treated precisely as if it were a piece of exposed carbon tissue. It was squeegeed upon a support—rigid or flexible, temporary or permanent. After resting a short time, the picture was immersed in warm water, and in a few minutes the paper upon which the emulsion was spread could be stripped off, and the gelatine, in proportion as it had not been influenced by light, dissolved away exactly as in the case of carbon printing. By this process a silver picture

is obtained, in which the image is free from gelatine in the deepest shadows, just as it is in the highest lights of a carbon picture.

Pictures by Mr. Warnerke's process can, of course, be intensified by methods not applicable to ordinary gelatine negatives. For example, any of the ways of toning or intensifying carbon lantern slides referred to a short time ago, or the old method of intensifying wet-collodion negatives with acid pyro and silver, will answer. As there is no gelatine in the shadows, it necessarily follows there is nothing to stain.

The analogy in the behaviour of a pyro-developed gelatino-bromide film to a bichromated one has been much overlooked by, if known at all to, modern workers, although it may have many useful applications.

GRADUATED VIGNETTES.

The beauty of a properly graduated vignette is, or should be, that it may be used in contact with the negative, and is not dependent upon a rotary motion or any other expedient for producing or improving its gradation. This being the case it is obviously worth the operator's while to devote especial care to the various mechanical details described in the previous article, more especially as, when a properly graduated *cliché* is once obtained, it may be reproduced photographically with comparatively little trouble.

That is, of course, assuming that the shape is one that is suitable for general use, because it goes without saying that there are shapes which can be adapted only to particular pictures. These, of course, will only be produced as specially required, the "stock" shapes of aperture being those—such as the ellipse or oval, the egg shape or irregular oval, and others assimilating more or less closely to the outline of the head and shoulders—that are found to be of pretty general utility. The shape alluded to refers simply to the aperture in the mask employed in vignetting, because, if the graduation be well performed, it ought to be difficult to recognise any shape at all, so imperceptibly does the shading fall away.

There is one other point to which attention may be drawn, namely, that the density of the vignetting screen should bear a proper relation to that of the negative, in order to produce the best results. For instance, a screen that produces a beautifully soft graduation when used with a strong negative would probably give a harsh and crude result when employed in conjunction with a thin and delicate one, and, conversely, the graduation that suited best a weak negative would be altogether unsuitable under opposite circumstances.

When so much care is required in securing, so far as mechanical means are concerned, evenness and uniformity of gradation, it follows naturally that equal, if not greater, care should be devoted to the preparation of the photographic surfaces concerned. Every one knows how painfully evident minute defects become in the plain background of a portrait or in the sky of a landscape negative, and it may be, therefore, easily conceived that the best vignetting screen will have its beauty and uniformity destroyed by minute faults that might pass unchallenged in an ordinary negative. Whatever the means employed may be, the material should be of the very best.

Perhaps the simplest and easiest process, and certainly the one we should recommend for a commencement of experiments, is the ordinary albumenised printing process. Albumen paper, whether ready sensitised or specially prepared, provides, with a minimum of trouble, a beautifully uniform printing surface, which, if slow in its action, is none the worse for that, since it enables the beginner to carefully watch and study the progress of his work. It is cheap, moreover, and easy of manipulation, and almost the only fault that can be found with the process, as applied to vignetting screens, is the additional length of time required in printing, owing to the want of transparency of the paper. This, however, can be greatly reduced by careful oiling or waxing, and need not form a very serious objection; indeed, many operators would prefer the slow printing, as giving a superior result.

Ready-sensitised paper answers perfectly well for the purpose—that is, of course, presuming it to be of good quality; but we prefer for such uses to sensitise the paper specially, floating the reverse or non-albumenised surface on the silver bath. By this means the image is formed more in the body of the paper, and shows greater density and gradation than when it is confined to the layer of surface albumen. In printing, the floated or non-albumenised surface should receive the exposure. It is purely a matter of taste whether such images are toned or not, so long as care is taken to carry the printing to a sufficiently deep stage to allow for the reduction that will occur where toning is not resorted to. Personally, we have a preference for non-toning.

Albumenised paper being available for the purpose, it might be supposed that gelatino-chloride would be equally so, but such is not the case. Neither the density by transmitted light, nor the uniformity of the layer of sensitive material is satisfactory, so we are reluctantly compelled to reject this material.

Where the opacity of albumenised printing paper is an objection, an admirable substitute is to be found in carbon tissue, and, as this can be obtained sensitised and ready for use, it forms one of the most convenient materials available. Besides this, the quality and character of the image it gives are eminently suited to the reproduction of delicate gradations, and the facilities afforded for the production of images of any grade of density are such as to specially recommend this process. It is true that the inability to watch the progress of the printing forms somewhat of an objection to its use, and the process has also been said to be unsuited to the production of vignettes, owing to the washing away of the finer gradations on development; but, if the latter operation be conducted on a proper surface, there is not the least difficulty in retaining the very finest gradations, and at the same time, if the printing be carried to a sufficient depth, a considerable amount of latitude exists in development, by which the strength of the image may be regulated.

In order to retain the more delicate gradations of the vignette, it is scarcely sufficient to develop on a plain collodion film, however carefully the operation may be performed. A very thin layer of gelatine, rendered insoluble by means of chrome alum, becomes necessary; a strength of five grains of gelatine and a quarter of a grain of chrome alum to each ounce will prove a satisfactory one, and should be applied *after* a collodion film if the vignette is to be stripped from the glass, or directly on to the glass if the latter is to constitute the final support.

Numerous methods of intensification, where such is required, are known to carbon printers, but these are mainly based on the principle of either staining the carbon image or forming a coloured or opaque precipitate within its pores. The bichromated gelatine image, it should be borne in mind, differs from

that of a gelatino-bromide plate in that it is formed of varying thicknesses of gelatine, the very highest lights being represented by clear glass or a total absence of gelatine. Now, it is evident that, if such an image be stained with a transparent pigment, it gains in intensity in proportion to its original gradations; this forms one method of intensification. But two solutions are often applied in succession to form an insoluble deposit in the layer of gelatine, as, for instance, nitrate of silver, followed by pyrogallic acid; but in this case there is no guarantee that the intensification is proportionate to the gradation, or even uniform in its character, since a perfectly opaque deposit may be formed on what ought to be the half-tones. Where, therefore, such methods are adopted, we recommend the staining method, and a very weak solution of potassium permanganate forms a suitable medium.

By either of the methods we have described the vignettes are produced in the form of films, which will be found generally more convenient than glass plates in adapting them to the negative. But other processes are available for the production of vignetting plates or glasses, which may be preferred by some. Simplest amongst these is collodio-chloride emulsion, a description of the method of using which appeared in these pages not long ago. Next to this may be named gelatino-chloride emulsion, both these processes being, like those already described, "slow printers."

Turning to the more rapid methods, which will be found useful, if not absolutely necessary, in many cases where the work has to be performed by artificial light, we have the choice of collodion emulsion and ordinary gelatine plates, the latter, of course, being much the more rapid. The particular methods of working these, so far as the chemical side of the question is concerned, scarcely need any description, the principal difference in procedure lying in the mechanical arrangements for the adjustment of the lighting.

Where film vignettes are required, the collodion emulsion plates will be found the more convenient, as, after development, they only require to be placed on a levelling stand, and a thick layer of plain gelatine poured over the surface and allowed to set. After drying, which will require two or three days, the compound film may be stripped from the glass with the greatest ease.

Of other processes that might be mentioned, there is the almost forgotten method of Mr. Warnerke, in which a gelatine film, on paper, is, after development, and without fixing, squeegeed on to glass, and treated as a carbon print, the undeveloped portions being washed away with hot water. For our present purpose glass plates instead of paper films may be used, the exposure being made *through* the glass; but it should be ascertained beforehand that the film is *soluble*, as the majority of modern plates are rendered more or less insoluble by the use of alum at some stage of their preparation.

Solar Prominences.—In the first number of *Astronomy and Astro-physics* some interesting recent results of photographing solar prominences are given by Professor G. E. Hale. An interesting coincidence is also noted of the same eruption having been photographed and also drawn by hand. It was one that took place on July 9 last year, the photograph being taken at Kenwood Observatory, and the drawing by Herr Fèuyi at Kalosca, Hungary. The general agreement in the form of the prominence is said to be very striking between the work of the hand and the camera.

Ruled Gratings.—Our readers have on previous occasions had brought under their notice the gratings ruled on a concave surface, by means of which Professor Rowlands has been able to secure such marvellous photographs of the spectrum exceeding in size anything before attempted in direct photography. Practical mechanics know the great difficulties attending the construction of gratings of such delicate character as is needed to produce a high-class spectrum. The machines hitherto employed by the Professor enable him to rule lines 50,000 to the inch, but he has just completed the making of a perfect screw which will enable him to make lines of the extraordinary closeness of one million lines to the inch. Lines so fine cannot be seen with the microscope, about 100,000 to the inch being the limit of vision when so aided. The new automatic machine is of marvellous construction, and has many devices to compensate errors; it requires six days' continuous working, day and night, to one grating of the size needed to study the constitution of the solar radiations.

Measurement of Liquids.—The upholders of the "pinch and drop" system of measuring allege, as one advantage of their plan, that time is saved in the operation. Practical men will deny the legitimacy of any such claim, and we should be inclined to side with them. There has lately been described in the *Chemical News* a method for the quick measuring of liquids which, if as advantageous in practice as it appears to be on paper, will sweep away even this excuse. A piece of glass tube is taken, and a cork is inserted at each end. Through the top cork a small hole is bored; this is closed on the under side by a valve of indiarubber cloth, with a piece of cork attached to it. Through the bottom cloth are bored two holes of about equal size, through which are passed two glass tubes, one of which may be curved till the legs are at a right angle. Two clips are attached to two pieces of indiarubber tube at the end of each of these glass tubes. The liquid to be measured is run from a reservoir into the apparatus through the curved tube by opening the clip. The liquid rises and lifts up the piece of cork, thereby closing the valve. There is now the desired quantity of liquid in the apparatus, which can be run out by opening the other clip, the valve meanwhile falling down, ready to let the air escape when filling again. It is obvious that a paper scale might be pasted upon this tube for measuring definite quantities less than the whole tubeful.

Carrier Pigeons and Photography.—Mr. W. B. Tegetmier devotes an article in last week's *Nature* to recommendations in favour of utilising carrier pigeons for carrying messages in times of war, and gives a map or plan of Europe, with the stations for pigeon service, which is there very general, indicated. Should such a service be initiated in this country, it would be to the benefit of photography, as our science is utilised to such an extent as to enable a single pigeon to convey a complete budget of news. During the Franco-Prussian War an immense number of micro-photographs were so made use of.

"The Pigeon Post."—Balloons were continually dispatched from Paris, carrying not only passengers, but bundles of letters, and the homing pigeons belonging to a few private individuals resident in Paris. After a time a distinct pigeon post was organized from Tours, outside the German lines. This pigeon post was recognised by the English authorities, and letters, at the cost of half a franc a word, were sent from Tours into Paris with as great a degree of rapidity as the pigeons could be sent out by balloon and conveyed from the place where they descended to Tours, for the purpose of being reflown into Paris. The letters, which were limited to twenty words, were set up in type, photo-micrographed by the wet-collodion process, the film removed from the glass and enclosed in small quills, which were then attached to one of the tail feathers of the bird. So complete is it stated that this organization was, that one pigeon could have carried into Paris the whole of the many thousand letters that were sent during the siege. There is no special skill required for this kind of work—indeed, any amateur conversant with the wet-collodion process could, with an ordinary camera and lens, reduce a whole page of newspaper to such dimensions as would enable it to be dispatched in the manner described. And not only could printed matter be so reduced, important views and plans could be taken by

an ordinary hand camera, reduced in size, and dispatched within a very brief period of time. There is a limit of definition with an ordinary photographic lens below which it would not be practicable to reduce the size. When the utmost minuteness is required, a microscopic objective is employed to produce the requisite amount of smallness of image combined with perfection in definition.

Animal Photography.—Tuesday's *Globe* has an article devoted to a description of Mr. Gambier Bolton's methods of working, his adventures, and the animal pictures he has obtained in the Zoological Society's Gardens and elsewhere. We gather that Mr. Bolton has secured the honour of Royal patronage, he having recently been commissioned by Her Majesty to photograph a number of inhabitants of the Royal kennels. Lions and tigers, it appears, are good sitters, while the elephant is not. Modern animal photography is conducted under infinitely easier conditions than, say, twenty or thirty years ago, when such men as Mr. Frank Haes did most excellent animal work. And yet the pictures of the present time, to our thinking, exhibit little, if any, advance upon those of Mr. Haes's, a number of which were shown at the Camera Club a few weeks ago.

"Automatic Photography" in Court.—A sitting for the public examination of the officers of the Automatic Photograph (Foreign and Colonial) Company was held before Mr. Registrar Brougham on Tuesday last. But the Earl of Kilmorey, the principal witness, and Captain Charles Wilson, the next important witness, were not present, the first being "detained" at Mentone, the second "failing to attend." The inquiry, which was not completed, elicited some curious and instructive information as to the disposal of the capital that was subscribed, and the amount of it that was not. No doubt the Earl of Kilmorey will be present at the adjourned inquiry, and will enlighten the world as to the details of his connexion with the affair. He is a very old amateur photographer—"instead of which" he became chairman of this ill-fated concern.

"Oil on the Waters" in Photography.—In our correspondence columns Mr. W. Vick, of Ipswich, informs us that having to photograph a house situated on a hill, at the base of which was a pond, the surface of which was covered with ripples, in taking a view looking up to the house, the ripples became a serious matter. Having three ounces of olive oil with him, Mr. Vick threw it upon the water, with the result that there was a subsidence of the ripples, and in the resulting photograph the reflections in the water were discernible, which was not the case before. Mr. Vick sends us a print from which we can confirm the presence of the reflections in the water. He asks if other photographers have tried the plan, and advises the use of more oil than he employed, as well as throwing it upon the water from the side from which the wind is blowing.

"Where Credit is Due."—One ought not, perhaps, to lay too great stress upon after-dinner speeches; but did not Mr. T. Sebastian Davis, in his speech at the dinner on Monday, credit the Society of Great Britain with rather more than its share when he attributed the introduction, or first publication, of almost all the important advances in photography to this Society? At one time this might have been said; but for a long term of years other channels than that of the Society have been selected through which to convey first intimation of discoveries, or even improvements. Many instances might be adduced in which the Society's aid was not evoked for their promulgation, such as the collodio-bromide and gelatino-bromide processes, or any of their cognates. The current processes of the period, such as platinum, kallitype, and bromide printing, or even the toning of bromide prints, have not reached the public through the medium of the Society: the valuable researches of Hurter & Driffield were ushered in through another channel; nay, even a feature of advance, cited as an instance by Mr. Davis—Chas. Bennett's discovery of a means by which the acme of sensitiveness was imparted to gelatine plates—was not given to or through this Society, but another, now non-existent, the original South London Society. Innumerable other instances could be adduced, such as orthochromatic photography, Waterhouse's reversal by thio-carbamides. While saying this, however, we fully recognise the great value of the contributions to the Society by such men as Captain Abney, T. R. Dallmeyer, and others.

GRINDING THE EDGES OF PLATES.

I.

Nothing adds more to the comfort of handling glass plates, either in development or in the form of finished negatives, than the removal of the sharp edges left in cutting; but very little, if any, attention is given to this point by plate makers or consumers. In former days, when the preparation of dry plates was conducted almost entirely by the user himself, grinding the edges of the glass before use formed one of the duties of the careful operator, and, though not absolutely essential, was very commonly resorted to in consequence of the comfort it added to the after-operations. Roughing the edges, too, was looked upon as a useful aid to preventing the collodion film slipping, and I remember buying as a regular commercial article many years ago a lot of plates that had not only had the sharp edges and inequalities of cutting removed, but which were also neatly surface-ground to the depth of an eighth of an inch on each side. I mention this to show the care that was devoted to little matters in those days.

It is, perhaps, too much to ask at the present day, and at present turn-out prices, that plate-makers should grind the edges of their glass before coating it with emulsion; but I am, perhaps, not alone in thinking that they might often do a great deal more than is done in that direction without over-burdening themselves with trouble, or getting their customers into too luxurious habits. The dark room, of all places, is the last to be chosen for the purpose of handling badly cut glass plates; yet who has not had to complain of lacerated fingers, and even blood-stained films, due to hurriedly changing a packet of plates that would make a glazier's apprentice in his first year blush?

The trouble is not so rife with the larger sizes, because, for one reason, these are actually cut before coating, and by competent workmen; but when we come to the smaller sizes, which are too often cut down after coating, the evil reaches its full height. In such cases everything is against the production of clean edges. The work is done by *feel* rather than by *sight*, and the heavy pressure necessary to penetrate the gelatine film is far from conducive to clean cutting, especially when the operator never served an apprenticeship to the use of the diamond, but simply "picked it up" as one of the adjuncts of plate-making. Under such circumstances, the wonder is not perhaps so much that plates are not better cut, but that they are cut as well as they are.

But, if we dare, not look for any considerable reform on the part of the manufacturer, it is at least possible to study our own personal comfort in using commercial plates, more especially as these run so generally now in the small sizes. The vision of erecting a grindstone as an addition to the furniture of the dark room is scarcely an engaging one from any point of view, and readers will perhaps scout the idea of interfering with matters as they are on that account alone. But a grindstone is by no means a necessity, at any rate in the form usually understood by that term, and represented by a heavy revolving disc of material requiring an extra hand to turn it. The preliminary steps, at least, to comfort may be taken in the dark room with very simple appliances.

Even in broad daylight a circular revolving stone is perhaps the very worst tool an inexperienced hand could apply to the purpose, as the principal end attained, failing the necessary experience, would be the opposite of that desired. A better result would be gained by turning the stone on its side, and using it as a grinding slab, though the comparative softness of the material scarcely fits it for the purpose. A piece of fine, hard flag-stone, worked to a smooth surface by a stonemason, would answer admirably, either in or out the dark room, though it forms a rather cumbersome piece of apparatus to move about when necessary.

I have for many years employed for the purpose an emery slab, which is at once harder and finer, and, if properly made, cuts as freely and keenly as the roughest grindstone. I at one time employed a square scythe "rubbing stone;" but this, while serving the purpose

fairly well, is too soft, gives off a lot of dust and grit, and is constantly requiring surfacing. The emery slab, on the other hand, costs little, gives the minimum of trouble as regards dust, and is sufficiently hard to last a long time without having its surface renewed.

In speaking of an emery slab, I do not, of course, mean a solid slab of pure emery or corundum, or even of the mixture of which small emery wheels are made; such a slab, if of sufficient size to be of practical use, would be a somewhat costly affair, whereas my substitute, while equally efficient, need cost but a few pence. It consists of wood faced with emery, but upon the method of "facing" depends entirely the character and value of the tool. I have tried a variety of plans, simplest and most primitive of which consisted in glueing a sheet of emery cloth on to a plane board, and this answered very well while it lasted, which, however, was not long. Then I was led to try a mixture of emery and shellac melted together, which was intended to be spread upon a flat surface; but I never properly succeeded in getting it out of the pipkin in which it was mixed. Next I tried a mixture of emery and Stourbridge clay made into a paste; but, as this had to be dried and *baked*, it was not only troublesome, but the wood would not stand the operation, and without that support it was no use.

After trying powdered emery dusted over a coating of shellac varnish, as used by jewellers and dentists, I had the "tip" given me by a working cutler to try *glue*, and this, the simplest and easiest, proved by far the best of all; indeed, it is surprising what a hard, durable, and, at the same time, free-cutting surface it gives. I have for five or six years used for all grinding purposes, for lathe and other tools, discs of wood faced in this manner with powdered emery, and find them superior to the ordinary emery wheels at one-twentieth the cost.

CONTINENTAL NOTES AND NEWS.

Jena Non-actinic Glass.—A new glass for laboratory purposes that will pass none but the red rays of the spectrum is said to be in course of preparation at the Jena Glass Works.

Lantern Exhibitions in Vienna.—Apparently the Viennese public take very kindly to lantern displays, over three thousand persons having, on one night, attended an exhibition organized by the Amateur Club of Vienna. Two hundred and fifty slides were shown, of which a portrait of the Emperor, His Majesty's study, the statue of Marshal Radetsky, and studies of Viennese life were the most popular.

Ceramic Paper Process.—In Guerot's vitrifying process, according to M. Pector, the photo-ceramic paper is sensitised with a solution consisting of bichromate of potash added to some unrevealed substance, and a print with a safe edge taken from a negative in the usual way. The picture is washed, is squeegeed in contact with the vitrifiable *plaque*, and the paper stripped. The image is then treated with a weak solution of permanganate of potash, is washed and dried, and finally fired.

Portrait of Stas.—The *Bulletin* of the Association Belge de Photographie, of which he was a member, gives a phototype portrait of Stas, the eminent Belgian chemist, whose death we recently announced. He was engaged for six years in studying the properties of bromide and chloride of silver. Some of his experiments were of such a delicate nature that he frequently had to sit up all night and watch the substance upon which he was working. It was from him that the late Dr. Van Monckhoven took many of his ideas in emulsion-making.

English Photographic Societies.—Dr. Phipson, the London correspondent of the *Moniteur*, informs the French public that there are now 114 photographic societies in this country. He says that the names, addresses, and objects of all these different societies are given alphabetically in—no, *not* in The British Journal Photographic Almanac for 1892; for, if he had drawn his statistics from *that* volume, he would have avoided the serious error into which he has fallen. There are now nearly 250 photographic societies in this country, Dr. Phipson.

Transferring Albumen Prints to Wood, Metal, Glass, or Porcelain.—If the surface is polished, says a contemporary, it should be well dried. A thin substratum of copal varnish is then applied to it, and the albumen print, toned and fixed, but still wet, is placed in contact with the varnished support, and well squeegeed down, print side to the varnish, of course. It is allowed to dry for about four hours, and then the back of the paper is moistened with a damp sponge, when it can be peeled off, the albumen image adhering to the varnish. This should then receive a protecting coat of varnish.

The "Association Belge."—Perhaps the Photographic Society of Great Britain might take a hint from the constitution of the large and flourishing Belgian Society we have named. Its headquarters are at Brussels, but sections are also established at Antwerp, Ghent, and Liège. Each section enjoys autonomy of administration, and the proceedings of all four are periodically published in the *Bulletin*. The central *Comité d'Administration* consists of members drawn from the various sections, and thus ranks, as it were, as a kind of grand council, to which the various sectional Committees are affiliated. May we hope one day to see sections or branches of the Photographic Society of Great Britain established in Liverpool, Manchester, Birmingham, and other large centres.

Idoine.—This is the name of a new toning agent, said to be suitable alike for prints in aristotype and albumen papers. It is in the form of a powder, and the proportions of a suitable bath are given as follows:—

Idoine powder	10 grammes.
Hypo	129 „
Water (filtered or, better, distilled)	1 litre.

The solution is ready for use at once, and the print is placed, without washing, in a quantity of it, sufficient to cover them. The tone of the image is at first sepia, and it then passes through various stages. When the desired tone is reached, the print is withdrawn and washed in several changes of water; slightly over-printed pictures are recommended for obtaining good tones.

RATIO OF GRADATION.

As Mr. Michael's letter, in your issue of the 5th inst., shows evidence of an imperfect acquaintance with our investigations, we shall be glad if you will kindly allow us to make the following reply; and, as we at once looked up the particular modification in development to which Mr. Michael refers, and put it to the test in our usual way, we thought the result might be of interest to your readers.

Mr. Michael is, apparently, under the impression that we hold that the ratio of gradation is unalterable, not only by modifications in the constituent parts of a developer, but that it is invariably the same whatever the developing agent employed. The former we do hold, the latter we do not. In our original paper we distinctly say: "There is a theoretical possibility that a plate may be rapid to one developer and slow to another, so as to require different exposures, according to the developer used."

Mr. Michael will also find from this paper that the primary object of our investigations was not to determine the precise function of development; this was a purely incidental, though necessary, inquiry in our search for a method of determining the relative speeds of plates. It is obvious that, before we could study the action of light upon the sensitive plate, it was necessary to ascertain whether modifications in the developer, within, at any rate, wide limits, affected our results, in order to be quite sure that these were due to the action of the light alone.

Another erroneous impression under which Mr. Michael labours is, that we have used the sensitometer in our investigations. This is not the case, as we do not attach any value to this instrument for experimental purposes. Our method of working is to submit the plates under investigation to the direct action of a standard light, and then

to ascertain, by means of our photometer, the relative amounts of metallic silver produced after development.

We also consider this method of experimenting far more likely to lead to the truth, and far more scientific than that of taking landscapes in the camera in the ordinary way. By our method the results can be measured, converted into numbers, and, as such, compared. The unaided eye will detect a difference, but is quite incapable of deciding what the difference amounts to. It is this method of quantitative determination which has been so long wanted in photography in order to decide matters which have hitherto been merely opinions.

As an example of the alteration of the ratio of gradation in development, Mr. Michael refers to a method of developing plates which have been exposed on subjects having great contrasts, which was propounded by Captain Abney in the *Year-book of Photography for* 1889. As we have said, we at once made an experiment to ascertain whether this method of development would produce any abnormal result. Our method of procedure was as follows:—We submitted a sensitive plate to the direct action of a standard candle at a distance of one metre, the seven exposures given varying from ten seconds to 640 seconds. After exposure, the plate was cut into two parts, which we will call A and B, each bearing the seven different light impressions. A was developed in exact accordance with Captain Abney's instructions, and B in an ordinary normal developer.

Development of A (Stock Solutions).

No. 1.

Ammonia	1 part.
Water	9 parts.

No. 2.

Potassium bromide	20 grains.
Water	1 ounce.

(*a*.) Soaked plate for one minute in—

No. 1	20 minims.
No. 2	40 ,,
Water	2 ounces.

(*b*.) Added one-thirtieth of a grain of dry pyro, and allowed to act for eight minutes.

(*c*.) Added another one-thirtieth of a grain of pyro, and again left to act for eight minutes.

(*d*.) Added one-third of a grain of pyro, and 20 minims of No 2. This was also allowed to act for eight minutes, after which the plate was well washed.

(*e*.) Applied new developer made up as follows:—

No. 1	40 minims.
No. 2	120 ,,
Pyro	1½ grains.
Water	2 ounces.

In about four minutes the required density was reached, and development stopped.

Development of B.

Ammonium bromide	1 grain.
Ammonia	2½ grains.
Pyro	1½ grain.
Water	1 ounce.

Development was complete in about six minutes.

The following are the results obtained upon measuring the densities of A and B, from a comparison of the ratios of which it will be seen that, even with such extremely different methods of development, the density ratios are practically unaltered.

Exposure.	A.		B.	
CMS.	Density.	Ratio.	Density.	Ratio.
10	·215	1·00	·240	1·00
20	·430	2·00	·445	1·85
40	·740	3·44	·810	3·37
80	1·190	5·53	1·300	5·41
160	1·580	7·34	1·760	7·33
320	1·890	8·79	2·215	9·22
640	2·195	10·20	2·560	10·66

Should Mr. Michael be disposed to think that the range of gradation we have taken is insufficient to decide the question, we may say that the total range of gradation which the plates we used was capable of rendering truly lies in between exposures of 40 and 320 candle-metre seconds. Beyond these exposures, the gradations fall into the period of under-exposure at one end, and into the period of over-exposure at the other end of this scale.

We are glad to have had our attention called to such a striking departure from ordinary methods of development, and to have had the opportunity of showing that even this does not, in any way, conflict with results we have before obtained.

F. Hurter & V. C. Driffield.

REFLECTIONS COMBINED WITH REFRACTIONS.

[A Communication to the Photographic Society of Great Britain.]

A year or so ago I contributed a paper to this Society on the subject of the effect of re-reflected images from the plate itself, and the effect on the final brilliancy of the image. On that occasion I showed how a bright portion of the image might be re-reflected from the surfaces of the lens itself, forming a secondary real image upon the plate; the lens itself in such cases acts as an image-forming combination corresponding to a reflecting telescope. There is, as I pointed out, a much greater likelihood of a detrimental interference upon the resulting brilliancy of the image, the greater be the number of surfaces, concave towards the plate. In the Petzval portrait lens, for example, there are two concave surfaces so disposed in the front combination, and three surfaces so disposed in the back combination. In the portrait lens introduced by my late father there are only two concave surfaces thus disposed, viz., in the front; again, in double cemented combinations of the rapid rectilinear type, there are the two concave surfaces towards the plate in the front combination only. In the single meniscus there are no concave surfaces towards the plate, and hence it is that there is no possibility of the formation of an image by re-reflection, from the plate back on to the plate.

Another point of interest that has a bearing on this subject is, attention to the diameter of concave surfaces that are thus exposed towards the plate. It was in the construction of the rectilinear landscape lens that I introduced in 1888 that my attention was first called to the importance of the defects that concave surfaces towards the plate might have in lens construction; the exterior element forming the corrector has a concave surface towards the plate, and for extreme brilliancy in the resulting image does not compare favourably with the cemented meniscus, and, in cases of great contrast, the appearance of what I term "ghost," as distinguished from "flare-spot," was very remarkable. By reversing the lens entirely in its place the ghost was no longer visible, the stop then being behind the lens and a different concave surface facing the plate. The effect of reflected light in employing this lens under ordinary circumstances seemed to have an agreeable tendency in slightly softening the image, which has been approved of by several of our leading photographers; but that is a matter outside the subject, and one of opinion.

In the drawings and calculations I made at that time, to prove that real reflected images were thus formed, I conceived the idea that concave meniscus lenses, or even convex lenses, with the posterior surfaces concave towards the incident rays, might be made use of for the formation of real images of considerable brilliancy by having the posterior surfaces silvered. First, speaking of single lenses, it can be easily demonstrated that it is possible to destroy spherical aberration; it is evident that the effect of a pencil of rays entering a lens and being reflected at the second surface, and passing out again, is equivalent to combining the well-known equations:—

(1) For the first refraction;
(2) For reflection;
(3) For the second refraction.

Put as a first approximation—

$$\frac{1}{f} = 2(\mu - 1)\left(\frac{1}{r} + \frac{1}{s}\right) + \frac{2}{s},$$

which shows that the effect on the pencil is that of two passages through the lens and a reflection at the second surface. This equation presumes that both surfaces are convex; if the first be concave, the resulting equation is represented by

$$\frac{1}{f} = 2\left\{\frac{\mu}{s} - \frac{\mu - 1}{r}\right\};$$

thus, to make the focal length positive, the first term in the bracket must be greater than the second, or the second surface s must be less than $\left(\frac{\mu}{\mu - 1}\right)r$.

For ordinary glass, it appears that a real image can be formed pro-

vided the radius of the second surface be less than three times that of the first.

Without troubling you with the details of the well-known formulæ for combining the refractions and reflections referred to in the second approximation, it can be shown that for ordinary glass the aberration is expressed by

$$\frac{1}{9}\left\{\frac{r^3}{1}+\left(\frac{r}{1}+\frac{5}{2f}\right)\left(\frac{1}{r}+\frac{1}{f}\right)^2\right\}+\frac{1}{s}\left(\frac{1}{s}+\frac{1}{3r}\right)^2=0.$$

It is evident that if r and s are both positive, or the lenses convexo-convex, the aberration cannot be destroyed, but if we assume the reciprocal of the first surface to be equal to $= -\frac{n}{s}$, the expression, by substitution in the equation above, will then be found possible to be solved; it becomes a cubic equation, and shows that the aberration may be entirely cured for parallel rays by making the first surface negative and a very little less than the second.

The drawback to such a mirror is the interference that will exist from the faint image formed by reflection from the first glass surface, and will therefore be useless for the formation of photographic images.

This subject has occupied the attention of Sir George Airy, who proposed to silver one side of each of two glass lenses to give the resulting reflector a Gregorian or Cassagranian form; the large mirror is a meniscus or double convex silvered at the back; for the Gregorian a small speculum is concave-convex. To correct the dispersion, leaving, of course, no secondary spectrum, one is positive and the other negative, their powers being inversely as the squares of their distances from the first image between the mirrors.

I have never seen such an instrument, and should be glad for information from any of the members, should they have come across such a construction, to know something of the performance of the instrument, as well as the angular aperture that has been attained. I have constructed one myself, of the concave meniscus form, in which the first surface is much deeper than the second, so that that interference from the faint reflection from it is not noticeable, and does not produce a detrimental effect; the aberration of the first reflecting lens being corrected by a negative lens, both surfaces of which are convex towards this mirror, the second one silvered again, and have thus produced a ratio of aperture to focus of one-half. The work in this respect is not quite completed, but I hope to exhibit it shortly at a technical meeting, when this, and other forms that I am preparing, may be of interest to you.

With regard to the other forms I refer to, I anticipate, from the calculations I have made, that important improvements may be obtained by silvering one side of compound lenses. A simple and interesting application of combining reflection and refraction can be illustrated in a novel form of view finder. I place a convex lens in a tube moderately near to a plain mirror (or it may be convex or concave), and by this means make one lens perform the work of two, and, by a proper selection of focus for the lens and its distance from the mirror, one can adjust its equivalent focal length to be exactly that of the camera lens employed; by making this lens of considerable diameter, and mounting it on the slide-carrier, and having a small screen above, and in the principal plane passing through the optical centre of the lens, adjustments as regards focus can be readily made in most cases of lighting; of course it would be difficult with a very strong light shining on the screen, which, however, may be mounted in a short tube.

Another application, in which I think there may be a considerable future, is the construction of large concave mirrors, silvered at the back, for lantern condensers, when employing the electric light, where too close a proximity to ordinary condensers would be accompanied by great danger of cracking, &c. By such a form of condenser a very large angle can be included, and with properly calculated surfaces to the mirror, and, perhaps, the addition, in front of the slide, of the corrector, may enable better results than have hitherto existed to be obtained. I am at present engaged on two such constructions; one to obtain the best possible result from the silver concave mirror, and the other by an additional lens in front of the lantern slide. The main drawback that suggests itself to its use is the difficulty that may arise from the shadow of the poles; it is possible that this may be overcome by revolving them. I do not think that another drawback that suggests itself, viz., the slight amount of light that reaches the slide from the naked light, will be of much importance, and that the naked light will, of course, be further away from the slide than it is from the mirror.

Another application that has struck me as useful for such class of reflecting mirrors, on account of the large angular aperture attainable, is in regard to use in naval work for scanning the horizon in dull weather; if such a mirror, a foot or more in diameter, were mounted in some manner, such as a ball and socket mounting from its centre, carrying an eyepiece on an arm, a rapid and powerful search might thus be made of the horizon.

T. R. Dallmeyer.

THE PHOTOGRAPHIC SOCIETY'S LECTURES.—III.

PHOTOGRAPHY AS A BRANCH OF TECHNOLOGY.*

A Branch of Technology of the First Order.

To all who are interested in the advancement of art and of science, photography appeals, therefore, as a branch of technology of the first order of importance; in saying that it appeals to art and to science for such recognition, it is evident that it appeals to the nation at large. Even to the "pure scientist," who is supposed to lose interest in a discovery as soon as it becomes practical, *i.e.*, commercial, this subject appeals for support, for, from the study of the photographic processes themselves, many important contributions to physics and chemistry have been made, and still greater results may be expected to follow from the investigations of scientific men in this direction. From its purely practical side, the claim of photography to be considered as a branch of technology will receive additional support when it is remembered how many distinct branches of manufacture it draws upon, or has, indeed, actually called into existence. Consider how it is dependent on the optician for the manufacture of lenses; consider, again, the special branch of cabinet-making and joinery which it has created in order to supply cameras and other instruments; remember, also, the boon which photography has conferred upon the chemical manufacturer by the demand for fine chemicals which it has created. Neither must it be forgotten that a new, and by no means unimportant, development in the manufacture of paper, gelatine, and albumen has arisen through the introduction of photography.

From every point of view, therefore, photography claims to be placed on the same basis as other branches of technology. The Photographic Society, I am happy to see, fully recognises this in the recent action which it has taken, and which is expressed in the report of the Affiliation Committee. I consider this an excellent move in the right direction. But it is easy enough for the Society to recognise the technical importance of its own subject; the difficulty is to move public opinion, and to convince the nation that we are behind other countries in this respect. The first step is to draw up, and circulate widely, an account of what is being done for photographic technical instruction on the Continent. I had intended, when first invited to lecture here, to offer some such statement, but I was glad to read, in a recent number of your *Journal*, that this task had been undertaken by Mr. Warnerke, and I hope that some means will be taken to bring his report under the notice of those interested in technical education. It is clear, from what has already been attempted by this Society, and from the opinions which have been expressed on all sides by those whose voices carry the weight of authority, that nothing short of a Photographic Institute will meet the requirements of the case. This, I most earnestly hope, will be the end and aim of every movement made by the Society. In the Cantor Lectures, which I had the honour of delivering before the Society of Arts in the spring of last year, I alluded to the absence of such an establishment in this country as "remarkable;" before this Society I am tempted to express myself more strongly, and to stigmatise its absence as a national disgrace.

A Photographic Institute.

Of course we all have more or less distinct ideas of what the functions of such an Institute would be. It is premature as yet to speak of the details of an institution which exists only in our aspirations. But, whatever may be the final outcome of the movement which has been started, the whole duty of such an institution might be summarised in the statement that its work would consist in spreading a knowledge of all that is known concerning photography, and in investigating that which is unknown. In other words, its duties would be, as in the case of kindred institutions, teaching and investigating. Without wishing in any way to intrude my opinions into the deliberations of your Council, I thought that I might with advantage avail myself of the present opportunity of submitting my own views with respect to this question of technical education in photography. In giving expression to these views I have in mind the consideration that the remarks which I may apply to our special subject apply to many other related technical subjects, and that the course which may be adopted in the starting of such an institute as that which we all wish to see come into existence may have a wide and important influence on existing notions concerning the whole question of technical education.

* Continued from page 89.

In the first place, then, let me express the hope that any action taken by this Society, in the direction of photographic technology, will be of the highest possible character. This may appear to you quite an unnecessary caution, but in involves a question of principle which it is very important to ventilate. After many years of apathy in this country, and after experiencing the inevitable consequence that we were being beaten in many branches of applied science by our Continental competitors, we underwent a few years ago a kind of revival in technical education. One outcome of this agitation was the foundation by the City and Guilds of London of that Institute in whose service I have had the honour of being employed. It is not for me to dwell upon the results which have flowed from the inauguration of that Institution, but it is no exaggeration to say that the wave of public opinion which raised it into existence is still surging throughout the country. The last decade has witnessed the rapid multiplication of technical classes and colleges, the foundation of technical associations, the growth of polytechnics, and, last of all, the diversion by the Government of the funds derived from the beer and spirit duty in the direction of technical education. The result of all this is that the means of technical education are being spread broadcast throughout the land.

Now it is one of our national characteristics that when we once wake up to the circumstance that we are behind other countries in any matter affecting our industries, or, I might say, when we have this unpleasant truth brought home to us by the superior workmanship or lower prices of our competitors—we are apt to seek remedial measures to recover our lost ground by what might be called indiscriminate and impulsive rushes. I am afraid that the technical education movement has, to some extent, been of this impulsive character. I am not going to be rash enough here to attempt to lay down any precise definition of what is meant by technical education; but a few months ago, the Duke of Devonshire, then Lord Hartington, made a speech at the opening of the Storey Institute, at Lancaster, in the course of which he said that technical education was not the teaching of any particular trade or handicraft, but rather of the scientific principles underlying the trade or handicraft. I think this fairly represents the opinions of those who have considered the subject, and I hope that this definition will be borne in mind in any movement which this Society may inaugurate. Are we adopting the best methods of technical education?

If now we review the situation, it will appear that the general spread of this educational movement may be taken as an indication that we intend to give battle to our competitors, and that we look to technical education to enable us to carry on the industrial campaign. So far so good; but our competitors, be it remembered, have been actively carrying on this branch of education during our long years of apathy. We have taken up our weapons rather tardily, and, as I just said, somewhat impulsively, and if we hope for success it behoves us to examine these weapons critically, in order to make sure that we are fighting on equal terms. In other words, are we adopting the best methods of technical education? This is the question which should be put in the foremost place before any measures can be taken by this Society in the much-needed direction of photographic technology.

So far as concerns those technical subjects in which, as in photography, chemistry is largely, if not entirely, the underlying science, I am bound to confess that the impulsive character of the technical education movement to which I have referred may, if not properly directed, run us altogether off the right track. One of the greatest functions of this Society would be to prevent such a calamity by diverting the tide of public opinion into the proper channel for its own particular subject of photography. The ideal technologist is the man who possesses a good general knowledge of the principles of those sciences underlying his industry, together with an expert special knowledge of his own subject. The first step in the training of a technologist is, therefore, to lay the broad foundation of general principles, and then to erect upon this foundation the superstructure of special knowledge. You must understand that I am attempting only to define an ideal technical training, having more especial reference to those subjects connected with, or based upon, chemical science. In the present state of affairs it cannot be denied that there are large classes to whom this method cannot be applied; there are specialists in every industry who know little or nothing of the scientific principles underlying their occupation, and in such cases the method may have to be reversed, and the instruction may have to proceed from unscientific specialism to scientific generalisation. But this method is, in my belief, only a makeshift which it may be expedient to adopt to meet existing conditions—it is not technical education in the strict sense of the word education, but the tinkering up of a system which has been bad from the beginning. It is only when we can deal with the student just starting on his career as a technologist that the true method can be applied; as things are, we have many years of tinkering work before us, and it is to the rising generation of younger technologists that the future industrial welfare of the country is committed.

(To be continued.)

Our Editorial Table.

A Flash Lamp.

By A. H. Baird, 15, Lothian-street, Edinburgh.

This lamp, designated the "Todd-Forret Magnesium Lamp," is intended for either instantaneous or continuous exposures. There is a reservoir for the powder, from which a jet is propelled up through

the centre of a large spirit flame. The cut shows its construction. It is well made, and sells at a low price, 12*s.* 6*d.*

Guide Pratique pour l'Emploi des Surfaces Orthochromatiques.

Par L. Mathet. Paris: Société Générale d'Éditions, Boulevard Saint-Germain, 24.

In this small work of some eighty-five pages the author deals with his subject in a manner which, to the practical photographer who desires to sensitise his own plates, will be found quite fulfilling the promise implied in the title—that is, of being a guide to orthochromatic photography. After instituting comparisons between ordinary and orthochromatic plates, and detailing the special precautions necessary in the preparation and employment of the latter, the author treats successively of coloured screens, colouring matters, and the sensitising of the plates, for which a number of formulæ are given. Of these we select one, which is said to sensitise for the yellow, red, and orange rays:—

Alcoholic solution of quinoline, 1 : 500	8 c.c.
Alcoholic solution of cyanine, purified by alcohol, 1 : 500	1 ,,
Ammonia, ·880	2 ,,
Water	200

The ammonia to be added last. Plates are left in this solution for from sixty to eighty seconds, and keep for about twenty days.

It is on the whole an excellent *brochure* on orthochromatic photography.

PATENTS COMPLETED.

Improvements in or Appertaining to Photographic Cameras.

No. 3823. Thomas Edward Corney Wilson, 28, Rufford-road, Fairfield, Lancashire.—*January* 16, 1892.

In detective cameras at the present time, where the plates fall out of the field of view, the camera has to be nearly double the depth that would otherwise be necessary in order to supply the box into which the plates fall; and where the plates fall vertically, exactly double the depth is required. Now, my invention is designed to enable the plates to fall vertically, and yet only to require very little additional depth. I place all the plates immediately behind the frame or obstruction, which regulates the distance from the object lens, so that as each in succession comes against this frame, they are in the field, and are ready for a photograph being taken. Behind the plates I place a dummy plate, pressed against them by a spring, and attached to this dummy plate a string, passing through the camera back. At the bottom of the camera proper I arrange the slide, which, being drawn back, leaves a hiatus immediately below the plates just wide enough for one plate to fall through; the plate cannot, however, fall, if pressed tight against the frame by means of the spring. Immediately under the body of the camera I hinge a box; this box is ordinarily held tight up against the camera bottom. Light is prevented from passing through the slot in the bottom, which is just clear of this box, by a curtain of black cloth, which is fastened to the camera bottom beyond the slot and to the box. The catch being withdrawn, this second box hangs vertically, and in this case a slit in this box comes immediately below the slit in the camera. Consequently, the slide having already been withdrawn whenever the string is pulled, the nearest plate falls at once into this box. The box then being pressed back into its original position, the plate falls to the bottom of the box; namely, to the side of the box when vertical farthest away from the slit. The result is that, if the box and the plate-holding box each hold a set of twenty plates, each of these twenty plates in succession can be exposed, and allowed to fall into the receiving box.

Improvements in or Relating to Magnesium Flash Lights.

(A Communication from Friedrich Hermann Felix Engel, 21, Graskeller, Hamburg, Germany.)

No. 7487. Reginald Haddan, 18, Buckingham-street, Strand, W.C., London.—*January* 16, 1892.

This invention relates to lamps and apparatus connected therewith whereby a flashlight may be produced by blowing powdered magnesium into or through the flame of the lamp. The object of the improvements is to provide a simple apparatus or means by which the necessary quantity of magnesium powder may be transferred from a reservoir thereof to the apparatus, by which it is to be blown into or through the flame so that the lamp may be safely and quickly recharged for another flashlight.

What is claimed is:—1. The combination with a blowing tube having recessed cavities for receiving a charge of powder to be blown, of a movable reservoir adapted to be moved over said cavities for filling the same by gravity, and thereafter to be moved from over said cavities whereby the latter are left charged. 2. The combination with a blowing tube having recessed cavities for receiving a charge of powder to be blown, of a movable reservoir adapted to be revolved on the said tube so that it may be moved into an upward position for filling the said cavities, and thereafter moved below the tube substantially as set forth, whereby the cavities are left charged.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

February 9.—Anniversary meeting.—The President (Mr. James Glaisher, F.R.S.) in the chair.

Messrs. H. Snowden Ward and J. W. Marchant were elected members of the Society.

It was announced that the Dundee and East of Scotland Photographic Association and the Leeds Photographic Society had been affiliated to the Society.

The Hon. Secretary stated that the Council had appointed Messrs. John Spiller, William Bedford, T. Sebastian Davis, and H. C. Jones as a Committee to deal with the question of the new methylated spirits.

The following is an extract from the report of the Council:—

During the year 1891-2 the following papers were read at the ordinary meetings:—*Standard Registering Slides and their Mode of Use*, by Sir David Salomons, Bart.; *Platinotype*, by W. Willis; *Photographic Methods of Obtaining Polychromatic Impressions*, by L. Vidal; *On an Undiscussed Point in the Illumination of the Dark Room*, by W. de W. Abney, C.B., R.E., F.R.S.; *Photographic Technical Instruction on the Continent of Europe*, by L. Warnerke; *Photo-micrography*, by A. Pringle; *Reflections combined with Refractions*, by T. R. Dallmeyer.

Special attention has been paid to the Technical Meetings by a Committee appointed for that purpose. Subjects chosen for discussion have been announced beforehand, and arrangements made for the exhibition of apparatus and specimens of work likely to prove interesting.

Among the various subjects selected may be specially mentioned *The Influence of Development on Gradation*. Dr. F. Hurter attended, by invitation, the meeting at which this question was considered. At another meeting Colonel Waterhouse read a paper on *Electro-chemical Reversals with Thio-carbamides*, giving the results of a number of experiments tried by him in the Society's laboratory.

Advantage was taken of Mr. Leon Vidal's paper on *Polychromatic Impressions* to organize an exhibition of chromo work, in which photography plays an essential part. A large number of exhibits were received, and about 280 visitors came to examine the exhibition.

In accordance with the announcement made at the last anniversary meeting, Mr. Leon Warnerke was good enough, on March 4, to deliver a lecture, with practical demonstrations, on *A Simplified Photo-collographic Process* to a crowded audience. It was desirable that this should be the beginning of a series of such lectures, but it was then too late to arrange for others to be delivered during that session.

During the present session the under-named gentlemen have favoured the Society by the delivery of similar lectures:—Mr. T. Bolas, F.I.C., F.C.S., on *The Relations of Photography to the Industrial Arts*; Mr. Chapman Jones, F.I.C., F.C.S., on *Distortion of Outline in Photography*; Professor R. Meldola, F.R.S., on *Photography as a Branch of Technology*.

Efforts will be made to provide courses of similar lectures from time to time. It is anticipated that these lectures will materially assist in the promotion of photographic technical education, and thus help to carry out one of the objects of the Scheme of Affiliation recently adopted by the Society.

In connexion with Mr. Warnerke's lecture, various firms working the collotype process were invited to send specimens of their work. An interesting collection of such prints was arranged, and attracted about 250 visitors.

The exhibition in Pall Mall may, on the whole, be considered as satisfactory.

There were 182 exhibitors, comprising 74 members and 109 non-members. Of these, 19 were foreign exhibitors (3 American, 1 Spanish, 1 Cape, 1 Belgian, 1 Swiss, 5 German, 3 Indian, 2 French, 2 Austrian). Six hundred and twenty-eight frames were hung, containing 1086 photographs, of which 399 were portraits and figure subjects, 508 landscapes, seascapes, and architectural, and 179 miscellaneous, as detailed above.

Two hundred and sixty-two lantern slides were exhibited, and sixty-two pieces of apparatus. The Aerial Graphoscope, designed by Mr. E. S. Bruce, was shown each lantern evening, and attracted considerable attention. The machinery for cutting dry plates, exhibited by the Paget Prize Plate Company, should also be mentioned.

During the exhibition twenty-eight lantern evenings were held, as against six or seven in previous years. These were well attended, and it is believed that this procedure is an improvement on that of preceding years.

It may be mentioned that some of the slides were contributed by our *confrères* in India, New Zealand, and Tasmania.

The number of tickets of admission issued free to members for the lantern evenings was limited, in order to avoid the inconvenient crowding previously experienced, and to make the exhibitions pecuniarily self-supporting. The financial result of this and the other arrangements adopted is fully dealt with in the Treasurer's Report.

The library has now been placed in order, and increased by the addition of about 180 new volumes.

It will be seen that the possession of its own home has enabled the Society to do a good deal of practical work which was formerly impossible. As examples of this may be mentioned the technical lectures, the exhibitions of colour work and collotype work, and the arrangement of the library in such a way as to be of practical advantage to members. The rooms have, on several occasions, been lent for meetings intended to promote the advancement of photography.

The possession of premises has also rendered possible the adoption of the Scheme of Affiliation above referred to, under which a certain number of societies have been affiliated, as already announced. Steps are being taken to carry out, as circumstances permit, the various objects contemplated by the scheme.

Great credit for the work carried out during the past year is due to the Assistant Secretary (Mr. H. A. Lawrance), who has done much more than was asked or expected of him at the time his services were engaged.

The question of lens and other standards, referred to in the last Annual Report, is still under consideration. In consequence of this subject having been brought before the Photographic Congress at Brussels, it has been thought advisable to postpone further action until the decisions of the Congress are published, after which the delegates appointed by the Society will be free to make their report.

The report of the Council was adopted, as was also the Treasurer's report after some discussion, in the course of which Mr. W. S. Bird (the Hon. Treasurer) explained that, but for the Guarantee Fund, the Society would not have had its own home during the past year. That fund was for three years as a set-off for deficiency of income, and with it there would be no loss to the Society for that period. This year they had had to call up each pound that was guaranteed, but next year he hoped it would be less. With ordinary caution there would be no necessity to interfere with the capital fund for the next two years. He suggested the formation of two small committees, one for increasing the number of members, and the other for considering the expenses of the annual exhibition, and the possibility of getting a more successful exhibition at less cost.

The Scrutineers reported that the following had been elected as the Council for the ensuing year:—*President*: Captain W. de W. Abney, C.B., F.R.S.—*Vice-Presidents*: Messrs. T. S. Davis, F.C.S., J. Glaisher, F.R.S., Sir H. T. Wood, J. Spiller, F.C.S.—*Council*: Messrs. W. Ackland, G. L. Addenbrooke, W. Bedford, W. S. Bird, A. Cowan, T. R. Dallmeyer, W. E. Debenham, W. England, J. Gale, F. Hollyer, F. Ince, Dr. G. L. Johnson, H. Chapman Jones, F.I.C., F.C.S., A. Mackie, Captain A. M. Mantell, R.E., A. Pringle, J. W. Swan, J. Traill Taylor, Professor J. M. Thomson, F.I.C., F.C.S., L. Warnerke.—*Treasurer*: G. Scamell.

The President, having declared the Council duly elected, said it remained for him to express his thanks to the Society for the confidence placed in him

for so many years. Many as those years were, from the first moment to the present he had done his best in order that the Society should take up a solid position, one that should increase photography and advance its interests in every way possible, and never in the slightest degree had he deviated from that position. The advance in photography since forty years ago was great indeed, but he believed that there was still a greater future before it. He joined the Society as a working photographer, but for years he had had other exacting duties which had prevented him from following many of the discussions which had taken place. Their President now was a different man, who could so occupy himself that he was quite *au fait* with what was passing. In inviting Captain Abney to take the Presidential chair he assured him that he did so with the greatest pleasure, and in the hope that during his presidency the Society might advance to such a degree that whenever the time came for him (Captain Abney) to part from the chair, he could look back to his occupation of it with the greatest pleasure.

Captain W. DE W. ABNEY said that he had a painful duty to perform. This was, although he had been elected President of the Photographic Society of Great Britain, to at once resign. His refusal of the nomination was, unfortunately, said to have gone in too late. He begged that his name might be obliterated from the balloting list, as in the interval between the time of nomination and his acceptance a great deal of hard work was entailed upon him which he could not possibly give up. New duties had also been forced upon him, and he found he should not be enabled properly to do his duty in the chair. He felt that the interests of the Society would suffer if he did not attend regularly, and devoted as much time to it as he ought to do. The Society was in a critical position, and a great deal of work would be created by the affiliation scheme. Things during the past year had not been so harmonious as they might have been, and he had not the courage to face a want of harmony. He should have been proud to serve, but his want of time compelled him to place his resignation in the hands of the members.

Mr. GLAISHER said he would exercise the influence of an old friend to tell Captain Abney that there were four Vice-Presidents, and he pledged himself that every one of them would do his best to assist him. He appealed to Captain Abney to allow himself to be inducted into the chair, and said that his success in that position would be the success of the Society.

Captain ABNEY, in yielding to the appeal, took the chair amid great applause, and said he would do his best, but they must take him with all his shortcomings.

Votes of thanks to the scrutineers, to the auditors, to the late Hon. Treasurer (Mr. Bird), were carried by acclamation.

The PRESIDENT (Captain Abney) moved a vote of thanks to the retiring President for his services during the past year. He wished him many years of happiness and health, and hoped he would never desert the old ship, but would come to the meetings of Council, and thus continue to exercise the influence of a President without the name.

Mr. GLAISHER briefly and feelingly acknowledged the vote. A change of President and a change of blood were necessary. Perhaps he himself had got fixed in a groove. He was pleased to have received their approbation, and thanked them for it.

In acknowledging a vote of thanks to him, proposed by Mr. Spiller, Captain A. M. Mantell said the work during the year was heavy, but he delighted in it. With regard to the future, if it was intended to ask him to continue as Hon. Secretary he would not be able to stand, as he lived at too great a distance from London.

This concluded the meeting.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

FEBRUARY 4, Mr A. L. Henderson in the chair.

Messrs. S. J. Beckett, Symonds, and B. F. Winks were unanimously elected members.

The Fry Manufacturing Company presented the Association with a copy of *Lantern Slides and How to Make Them*, by Mr. A. R. Dresser, and the Eastman Photographic Materials Company sent two dozen packets of bromide paper for distribution among the members.

Mr. W. COLES said that at a former meeting Mr. Freshwater had read a communication from a friend in India implying that bromide prints lacked permanency in damp climates, and Mr. John Howson had stated positively that bromide or chloride prints were absolutely permanent, and had quoted certain authorities in support of the statement. He (Mr. Coles) called Mr. Howson's attention to the fact that deterioration existed in such prints, but was told that it was not the case with prints prepared by the Ilford Company. He produced two copies of the ALMANAC for 1887, having alpha prints as frontispieces prepared by the Ilford Company. One of them had certainly deteriorated, as they could see, and he would like to know whether it was due to iron in the paper or improper fixation. There was no doubt that gelatine prints were more permanent than albumen prints under certain conditions, but gelatine in contact with paper that was damp was liable to absorb moisture and change in the air. Professor W. K. Burton had been quoted as saying that bromide prints were absolutely permanent, but he (Mr. Coles) thought that Mr. Burton was too careful to make such a statement. What he said was that he saw no reason why such prints should not be permanent. There was no writer more modest or careful in his statements than Professor Burton. The two copies of the ALMANAC had been kept together in a box most of the time in a dry room, where there was no gas.

Mr. W. E. DEBENHAM said he thought that if any one gave out such prints as permanent, after what Mr. Bolas said a few weeks ago on the subject, they would be doing a very great wrong. It was a great mistake to attribute fading to the albumen or the gelatine; the vehicles were rather the accidents than otherwise. The condition in which silver was thrown down by development differed from that obtained by printing out.

A print from the margin of the deteriorated print was handed to Mr. Haddon, who undertook to test it.

The subject for the evening was *Means of Obtaining Clouds in Negatives at the Time of Exposure*, and a few prints having fine cloud effects, produced by means of Micklewood's shutter, were handed round. It was understood that the shutter would be forthcoming at a future meeting.

Mr. DEBENHAM suggested that something might be done by the use of a yellow screen either inside or outside the lens, and slanted in different directions. If outside, and tilted, the lower part of the picture would be a larger thickness of the yellow screen than the upper, and so one could get a great deal more obstructing power with the sky than with the foreground.

Mr. E. MILNER thought that a good many clouds were lost by over-exposure. His method of getting clouds was to expose correctly, and use a small amount of pyro in the developer to commence with.

The CHAIRMAN remarked that he had some clouds in a negative which had been over-developed; there were no clouds until the negative was reduced. Mr. Dunmore had sketched some clouds on ground glass for him, which could be included in a negative by superposition.

Mr. J. S. TEAPE exhibited a number of prints, the clouds in which had been obtained in the negatives. They had been developed with a very small quantity of pyro to start with.

Mr. MILNER said that a thin film sometimes gave good clouds through there not being sufficient silver on the plate to clog up the skies.

It was understood that the subject would come under discussion at a future date; and, the Chairman having announced that Mr. S. Herbert Fry had promised a demonstration of his new enlarging lantern on an early occasion the meeting terminated.

Camera Club.—February 4, Sir G. R. Prescott in the chair.—Mr. ARCHER CLARKE gave, on behalf of the Incandescent Light Company, an account of the Company's lighting, and its applicability to various purposes. A demonstration of its use in the optical lantern was given, lantern-slide pictures being projected on the screen. The bulk of the evening was devoted to an address and demonstration by Mr. S. Herbert Fry, who practically illustrated the working of a newly constructed enlarging lantern, which, without the use of condensers, gave an equal illumination of a large negative.—On February 18, Mr. S. B. Webber will read a paper on *Some Experiments in Orthochromatic Photography*.

North London Photographic Society.—February 2, Mr. G. J. Clarke in the chair. Mr. Gregory, representing the Eastman Company in the absence of Mr. H. M. Smith, introduced the Company's series of Kodak lantern slides, prefacing the exhibition by a brief description of the latest Kodak improvements. The slides, representing scenery in England and other parts of the world, were highly appreciated, many of them being remarkable for their beauty as pictures, as well as for their perfection as photographs, and all showing the capabilities of the Kodak in its various forms, and the power and delicacy of the rollable film. A vote of thanks to Mr. Gregory and the Eastman Company, and also to Mr. Grover, a member of the Society, who most successfully undertook the duty of showing the slides with a new special lantern of Homphries' make, concluded the proceedings. The next meeting will be on February 16, when Mr. J. Weir Brown will read a paper on *Uranium Toning of Bromide Prints*.

North Middlesex Photographic Society.—February 8th, Mr. C. Beadle in the chair.—Thirty-seven members were present. Number of queries were found in the question box, ranging from the elementary to the abstruse, and, as is frequently the case, the simplest of the queries led to animated and interesting discussions. The Chairman produced a very successful example of combination printing. As the foreground, printed from one negative, projected irregularly into the middle distance printed from another, details of working were asked for. The CHAIRMAN said that, after printing the foreground, he had painted it over with burnt sienna, finding it much easier than cutting out a mask. The distance was then printed in from the second negative. Mr. Cox passed round a number of negatives and prints showing marked peculiarities in development and general treatment. He also exhibited a shutter capable of giving exposures from one-tenth of a second to any longer duration the operator might require. Mr. Marchant then showed the fuzee flash-light apparatus, by the aid of which two portraits were taken, an extra-rapid plate lens working at *f*-6. These were developed successfully by Mr. H. Smith with para-amidophenol. Mr. SMITH read a short paper on the developer, giving formulæ and his experiences with it, and showing negatives of great softness and good printing density which he had obtained by its use. Mr. Gandon then presented the Society with a very fine framed enlargement of a portrait of the President, which will in future adorn the walls of the room. Mr. Chipper passed round for inspection some cheap lines in cameras, lenses, &c. A lens of 4½ inch focus, rapid rectilinear, working at *f*-8, which a member had found, by trial, to cover a half-plate when working at *f*-22, and selling at 4*s.* 6*d.*, attracted much attention as being suitable for hand cameras. The annual dinner was announced to take place on March 12th. Votes of thanks to those who had taken part in the work of the evening brought an interesting and enjoyable evening to a close. February 22, Mr. T. Smithies Taylor will address the Society on *The Use and Design of Photographic Lenses*, illustrated by means of the lantern, and will explain how beginners may test lenses for standard qualities.

Polytechnic Photographic Society.—February 5, Mr. W. E. Debenham in the chair.—Mr. H. W. BENNETT read a paper on *Elementary Notes on Photographic Lenses* [this will appear in a future number]. After the paper had been read, and the various diagrams explained, the CHAIRMAN emphasised some of the important points and the almost boundless field of study which the subject of the paper presented. Before the meeting closed, Mr. Debenham drew the attention of the members to the importance of backing their plates, and gave them some sample bottles of a preparation which he considered most useful for the purpose. The preparation consists of burnt sugar, or caramel, with a little gum water and spirit, and this is poured on to burnt sienna to form a thick cream. The mixture is applied to the backs of the plates with a soft camel-hair brush. Mr. Debenham said that he did not trouble to wash off the backing before development, as he had not found it affect the developing solution in the least.

South London Photographic Society.—February 1, the President (Mr. F. W. Edwards) in the chair.—A number of 24×20 uranium-toned enlargements on Naturalistic bromide paper were sent by the Fry Manufacturing Company. Donations of books to form the nucleus of a club library were then announced, after which Mr. MAURICE HOWELL, M.P.S., read a paper on *The Chemistry of Photography*. The lecturer dealt with the subject historically, noting carefully the chemical changes which took place in working the earlier processes of photography, viz., Daguerreotype, calotype, Talbototype, Archer's collodion process, as well as the modern methods of producing negatives and positives. A large number of experiments, made from time to time with the view to improving the art, were also dealt with. It may be mentioned that Mr. Howell's interesting collection of Talbototypes of his own production at the Crystal Palace Exhibition, 1889, were much admired. Mr. Slater brought to the meeting a new pattern half-plate camera of good material and workmanship, which he is about to put on the market to be sold at the low price of 4*l.*, with three double dark slides.—February 15, Meeting at Hanover Hall, Hanover Park, Peckham: *Artistic Photography*.

Brixton and Clapham Camera Club.—February 4, Dr. Reynolds in the chair.—The Chairman briefly introduced Mr. PRINGLE, who gave an address on *Development*. The subject, he remarked, was a broad one, and he would confine his attention to the main features of the several developing agents. He denied the theory that after a plate had been exposed, rightly or wrongly, development could have no material effect on the result. A photographer requires to produce a good negative, *i.e.*, one which will produce a good print. To attain this result one had the option of five developers, viz., pyrogallol, eikonogen, ferrous oxalate, hydroquinone, and para-amidophenol, and he advised their use as follows:—Hydroquinone, for pictures requiring strong contrasts, lantern slides, &c.; Eikonogen, where a minimum of exposure had been given, as in hand camera work; Ferrous oxalate, where extreme clearness was required (Mr. Pringle said he did not consider this was used as much in this country as it should be); Para-amidophenol (rodinal), the same remark applies here as to eikonogen, but its action is even quicker. Mr. Pringle said he considered rodinal a good developer, but recommended that the amount of water to be added should be only two-thirds of that contained in the instructions. In conclusion, the lecturer said that where there was any doubt as to exposure, and for general all-round work, he had found nothing to come up to good old pyro and ammonia.

Lewisham High-road Camera Club.—February 5, Mr. Alfred H. Miles in the chair.—Mr. J. TRAILL TAYLOR gave an address on *Some Bye-paths in Photographic Optics*. His remarks had main reference to the influence of concave lenses when used in conjunction with ordinary photographic objectives. Lenses and pictures were shown in illustration of his remarks, and copious use was made of the black-board by the speaker.

Croydon Camera Club.—February 1, Annual Meeting.—The elections resulted as follows: *President:* H. Maclean, F.C.S.—*Vice-President:* B. Gay-Wilkinson.—*Council:* Messrs. Arthurton, Blow, Burrows, Hirst, Neeves, Oakley, Overton, and Packham.—*Auditor:* W. Daniells.—*Treasurer:* A. J. Sargeant.—*Secretaries:* Messrs. White and Isaacs. The annual dinner will be held next month. On February 15 Mr. Weir Brown will lecture on *Warm Tones on Bromide Paper*.

Richmond Camera Club.—February 5, Mr. Cembrano presiding.—Monthly lantern show. The attendance at this meeting was about the largest on record.

Crewe Scientific Society (Photographic Section).—January 25, Mr. Earl presided.—Mr. PAUL LANGE lectured on *Norway and its Wonders*. Mr. Lange said he was proud to be called upon to deliver a lecture on so interesting a country as Norway, and, after describing this favourite resort, he hoped it would result in inducing many present to pay a visit to that country. Having described the route from Crewe to Hull, thence by steamer to Bergen, he gave a description of the most enjoyable route for tourists and photographers to follow. The views thrown upon the screen were excellent, giving an admirable illustration of life amongst the mountains of Norway. The views were charming in themselves, and the lecturer's comments on the beautiful scenery greatly increased the pleasure of his audience. The cloud studies were magnificent.

FEBRUARY 3.—A *conversazione* in connexion with the above Society was held, when a good display of photographs was on view in the Council room, including a collection by Mr. Paul Lange, Mr. A. H. Hignett (Crewe), Mrs. J. U. Hignett (Chester), photographs and transparencies by members of the Section, and a display belonging to the London and North-Western Railway Company, lent by Mr. F. W. Webb. The Crewe Photographic Company, Limited, had an excellent show, including the Autotype and Alpha processes. On February 24, Mr. A. H. Hignett on *Highland Scenery*, to be illustrated by about 120 limelight views.

Halifax Camera Club.—February 1.—An exhibition of slides was held at the Club rooms. It was decided during the evening to have a portrait competition at the next meeting, confined to the amateur members of the Club, the portraits to be taken in the Club studio; and Mr. M. Manley offered an automatic plate-rocker for the best portrait exhibited.

Leeds Photographic Society.—February 4.—Dr. E. H. JACOB, M.A., lectured on *Practical Photo-micrography*. The lecturer described his apparatus, which was an adaptation of an ordinary microscope, and comparatively simple, yet efficient, as he proved by some excellent lantern slides shown upon the screen. The lecturer read a letter from Mr. William Kingsley, a brother of the late Canon Kingsley, which he had just received, and in which he incidentally referred to his suggestion, in a paper read before the Society of Arts in 1851, of the possibility of photographing the heavens, and by that means discovering new stars. The suggestion was then so little thought of that it was omitted from the paper as published by the Society. The Society has decided to hold an exhibition of members' work during the current year.

Lewes Photographic Society.—February 2. Samples sent by the Eastman Company of their new rapid bromide paper were given round to members, many of whom promised to bring the results of their experiments to the next meeting. The result of the competition for the best print illustrating *Toil* was announced, the award going to Mr. Percy Morris, who takes the exposure-meter presented by Mr. Watkins for competition among members of the Society.—Mr. WIGHTMAN then read an able paper on *Platinum and Bromide Printing: A Comparison and Contrast*. In dealing with the subject, he pointed out that, although in a properly executed platinum print there were certain qualities which could not be excelled or even equalled by bromide, yet for ease and certainty in working, combined with its adaptability more or less for the greater percentage of negatives, the balance lay in favour of the latter.

Midland Camera Club.—February 5, Dr. Hall Edwards in the chair.—The HON. SECRETARY reported that Mr. W. J. Spurrier had been elected Assistant Hon. Secretary and Librarian. A suggestion was made that at the end of the winter session a *conversazione* and exhibition of members' work be held, and the Council are considering the matter. The Hon. Secretary showed Chadwick's lecturer's reading lamp, and Dr. Huxley the "Holiday" developing lamp. Professor ALLEN then gave his paper upon the *Philosophy of Restraint in Development*, which he illustrated profusely by diagrams, &c., upon the blackboard, samples of negatives, and lantern slides. In the course of an interesting paper he said he could only agree with Hurter & Driffield up to a certain point, and showed three slides as a proof. Each had received about fifty times the correct exposure, one developed with normal developer completely solarised, one restrained considerably was about right, the third, with previous soaking in restrainer and large proportion in developer as well, gave the exact appearance of under-exposure. He also expressed a very strong objection to weak developers, and explained his reasons by diagrams of the film and image formed.

Rotherham Photographic Society.—February 4, Mr. E. Isle Hubbard, M.S.A., presided.—The SECRETARY reported with regard to the arrangements for the second annual exhibition, to be held in the St. George's Hall, Rotherham, on Tuesday and Wednesday, February 23 and 24. The venture, he said, promised to be most successful from a photographic point of view, and the loan collection of exhibits would greatly add to the interest. Specimen packets of Eastman bromide paper were distributed for trial purposes. Mr. G. T. M. Rackstraw (a Vice-President) gave a demonstration on lantern-slide making by contact, using ordinary commercial lantern plates and hydroquinone, with hydrate of soda developer. Toning, &c., was also illustrated.

Sheffield Photographic Society.—February 2, Mr. B. J. Taylor in the chair.—The SECRETARY announced that the Eastman Company had sent a few samples of their new bromide paper for trial by the members.—The prizes for the annual competition were presented to the following gentlemen, viz., Messrs. Crowder, Beck, and Bromley. The negatives of the winning pictures were passed round and admired.

Edinburgh Photographic Society.—February 3.—The first business was a demonstration of some of the different methods of carbon printing and development by Mr. James McGlasham. The lecturer stated that his experience had not been a lengthened one with this process, but, so far as he had worked it, and with sedulous care, he felt certain he was right in bringing before the Society the results of his experiments. Mr. McGlasham then proceeded with his demonstrations of practical work, showing everything but the actual exposure under a negative, with much satisfaction to the amateur portion of the audience. Messrs. E. L. Brown, John Ednie, and H. Houstoun Ross were balloted for and admitted members. In the report of the Council upon the proposed club rooms for the Society, it was stated that return postcards had been sent to all the members in full connexion with the body, 370; and that of this number only 111 had interested themselves in the question, and of that number 74 were in favour of the proposed change in the constitution of the Society, and 35 voted against the change. In the circumstances, action was delayed, especially with relation to proposed premises in George-street, but remitted the whole subject back to the Council to endeavour to obtain not only working and recreation rooms, but also a sufficient hall for the general meetings of the Society and the transaction of its ordinary business.

Glasgow Photographic Association.—February 4, Mr. William Lang, jun., F.C.S. (President), in the chair.—Three new members were elected, viz., John Brown, 8, Gordon-street; Alexander Macdonald, Brodick; Charles Sweet, Rothesay. It was unanimously agreed that the Association become affiliated with the Photographic Society of Great Britain. The construction and use of Dallmeyer's new telescopic-photographic lens were explained to members. Views were shown on the screen, the subject being a church half a mile distant, taken from the same position with an ordinary lens and with the new lens, the size of the image produced by the latter being six times larger than that by the former instrument. Uranium toning of bromide prints and of transparencies was discussed and examples shown.

Dundee and East of Scotland Photographic Association.—February 3, Mr. J. D. Cox (President) in the chair.—The PRESIDENT intimated that the Council had voted the sum of 3*l.* 3*s.* to the Maddox Testimonial Fund. He also intimated that the Association had affiliated with the Photographic Society of Great Britain. A demonstration was given of the stripping and enlarging powers of "Cresco-Fylma." Two negatives were treated with the solution, and in a very short time the films were removed from the glass. After soaking for some time in water the films were floated on to a larger-sized glass. This was done successfully, there being no distortion, but very little enlargement, probably owing to too cold water being used for washing and also to the plate not being suitable. "Cresco-Fylma" should prove useful for removing the films from cracked negatives, allowing them to be placed on new glass; and also in carbon printing, where a reversed negative is necessary to save double transfer. Demonstrations in enlarging were then given by Mr. G. G. Maclaren, who exhibited his method of working. His apparatus consisted of a two-wick Sciopticon lantern, to which was attached a quarter-plate camera. The negative was placed in a groove inside the ground-glass screen, thus having the ground glass between the condenser and the negative, this arrangement getting rid of the light mark on the enlargement caused by the dark space between the flames. An enlargement was successfully exposed and developed before the meeting. The prizes in the "Animal Studies" competition were awarded to (1) V. C. Baird and (2) G. G. Maclaren.

Photographic Society of Philadelphia.—January 13, Mr. Joseph H. Burroughs in the chair.—Mr. F. E. Ives exhibited one of his cameras for composite heliochromy. With a lantern objective having only one (large) aperture, this camera produces three sharp images, exactly alike as to size and perspective and on one plane. Mr. Ives stated that such a camera would prove to be a practical necessity for composite heliochromy, and he regarded it as an optical triumph. The subject announced for discussion, viz., *The Permanency of the Undeveloped Image on Dry Plates—What Conditions influence it?* was next taken up. M. Pancoast stated that some time ago he purchased three dozen plates of a well-known make. He used one dozen with excellent results at the time of purchase; the rest he laid aside, and did not use them until May, 1891, when he exposed four, and found them all right. On May 16 he exposed six more on landscapes and interiors, giving rather full exposures. These were kept in the holders until August 12, then transferred to a box containing old-style separators and put away in a dry place, standing on edge. A week ago Mr. Pancoast commenced development. On placing a fully exposed landscape in pyro and potash developer, no trace of image appeared. A second plate, treated to a dilute alkali bath previous to the pyro, then subjected to a prolonged and forced development, produced no better result. A third plate, landscape, hydroquinone developer, still no result. A fourth plate was next tried in a mixed eikonogen and hydroquinone developer, and, strange to say, a very fair negative was the result. He then tried some of the unexposed plates on neighbouring houses, producing good negatives. A plate of another man, purchased in 1889 and packed with the others, subject to the same conditions, on development with hydroquinone, resulted in a good negative. Dr. Mitchell said it was generally recognised that eikonogen would bring out details that pyro would not. He had several times used pyro on much underexposed plates, and, notwithstanding the use of a large quantity of alkali, he got hardly any image. He remembered one or two cases where, noticing fog on the edges of the plate, he had poured the developer off, washed the plate, and put it in eikonogen developer, the result being an almost instantaneous flashing up of the image—so quickly, in fact, as to give one the impression of an over-exposed plate. While he could not explain or give any good reason why Mr. Pancoast's plates did not come up properly, he thought there was no question that eikonogen would often bring out an image that pyro would utterly fail to produce at all. Mr. Earle stated that he had tried similar experiments in this direction. He had purposely carried exposed plates in the holders for six months and more, and, on development with the eikonogen, had obtained as good negatives as he ever did. The developer was eikonogen—not hydroquinone and eikonogen—from which he judged that in the mixed developer it was the eikonogen that was the more active agent. Mr. Carbutt said that his experience had been quite contrary to Mr. Pancoast's. He had made several hundred exposures in Europe in 1890, and they were not yet all developed. He had developed from time to time, and had found no decrease in the image—if anything, rather an increase. Last week he developed two packages that had been exposed in 1889, and they had attained such an extreme rapidity that it took a very acid ferrous oxalate to get any decent image at all. With the ordinary eikonogen and hydroquinone developer they were entirely beyond control. Dr. Mitchell said that eikonogen, under certain aspects, was next to the new para-amidophenol, a very energetic developer. It seemed to go to a certain point, however, and then stop, so that, while one got a great deal of detail in the image, the required density would have to be obtained from hydroquinone. A combination of eikonogen and hydroquinone was very like a partnership between good fellows. There was one fault which he believed existed in all gelatine dry plates, and which increased with the rapidity of the emulsion, and that lay in the boiling of the emulsion. In this boiling the silver reaches a state of strain, so to speak. The particles of silver, being in a state of molecular separation, seem to be hanging at a point where there is a certain amount of tension. Now, some unknown circumstances—it may be the character of the weather, the temperature, or the condition of moisture in the atmosphere at the time the emulsion is made—serves to start a disruption, gradually at first, but increasing, so that after a while the emulsion becomes utterly insensitive. Then, again, it may be influenced by the action of the light in making the exposure. The impression of the light on the sensitive surface may be just enough to start molecular disruption, which increases in a few weeks, utterly changing the character of the plate and preventing any image being brought out. Two or three summers ago a former member of the Society made an excursion to the Adirondacks, taking with him quite a large number of plates. They were a new lot, just from the factory, and he omitted to test them before he went away. However, he made a number of exposure, and when he came back started in to develop. He failed utterly in getting an image; the whole lot were bad. Mr. Bell asked Mr. Carbutt if he knew whether manufacturers to-day used any tanning at all in making the emulsion. Mr. Carbutt could only answer for himself. He did not use any. Mr. Chapman had been troubled with the film negatives darkening from the edge inward when kept several months after exposure, the trouble increasing with the length of time they were kept, until, in some cases, it covered the film entirely. Mr. Wilson suggested soda in the packing or separating paper as the cause. Mr. Carbutt recommended packing in waxed paper as a preventive of fogging from the edges. Mr. Brown favoured the old-time method of packing plates tightly together with a piece of orange post-office paper between each pair. Plates packed in that way, very tightly wrapped together, he had kept for four or five years, and they were as good at the end of that time as when he bought them. The present method of separating plates permits the circulation of air between them, carrying with it gases and impurities which would tend to injure the plates, and bring about the blackened edges spoken of by Mr. Chapman, extending finally to the centre of the plate. Some time ago he placed some plates, that were working admirably, into his plate-holders, where they remained over two months. When exposed and developed, he found this blackening upon the edges. Curiosity prompted the trial of some of the plates he had kept in a tin box in the same paper packages in which they had been received. Result: no blackening. In the former case the plates in the holders were exposed to the air, whereas those in the paper box, enclosed in a tin box, were kept from contact with the air; none could get in. He would suggest that the makers pack their plates closely together, rather than separate them, as was now done. In his experience, those packed tightly did not rub or scratch.

Madras Amateur Photographic Society.—January 11, Annual General Meeting, Mr. Dunsterville (President) in the chair.—The Committee's annual report was read, showing excellent results so far as the numbers and financial position were concerned, there being more members on the rolls, and a cash balance in the Treasurer's hands of nearly 600 rupees; but the work done during the year was not satisfactory, the number of competitors at the half-yearly competitions being smaller, and the pictures exhibited not being up to the former high standard. It was also pointed out that the number of members attending the monthly meetings was getting smaller and smaller. The President, who originally had had most to do with the formation of the Society, had consequently given notice of a resolution that it would be advisable to close the Society. In bringing forward this proposition he stated that he would be exceedingly sorry if it were carried; he had given the notice in order to try and bring matters to a climax, and to get the members to do something to prove their interest in the Society—if they had any! The Secretary seconded the resolution, stating that he agreed with all the President had said. A general discussion then arose, in which the members present gave their ideas of what might be done to make the Society of more use and interest to its members; and, in the end, it was proposed by Mr. C. Mickie-Smith, and seconded by Mr. Stuart, that the Society should not be wound up, but that it should be left to the new Committee, to be elected that evening, to do whatever they considered necessary to ensure better attendance at the meetings, and more competition at the half-yearly prize givings. The amendment was carried *nem. con.* The following were then elected as the Committee for the ensuing year:—*President:* Mr. C. Michie-Smith (Government Astronomer).—*Vice-Presidents:* Messrs. E. W. Stoney, M.I.C.E., and C. Slater.—*Committee:* Surgeon-Major S. L. Dobie, I.M.D., Messrs. W. M. Gerrard and A. E. Lawson, Dr. G. Offert, Ph.D., Captain A. D. G. Shelley, R.E., and Mr. A. O. Wood.—*Secretary and Treasurer:* Mr. F. Dunsterville, Royapuram, Madras. It was then resolved to subscribe two guineas to the Maddox Testimonial Fund, and, with votes of thanks to the outgoing President and Secretary, the meeting closed. If photographic dealers and manufacturers will send the Secretary samples of their goods or catalogues with prices, he will be very happy to distribute them among the members, who reside all over the Madras Presidency; the number of members is about fifty.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

FORENSIC IDENTIFICATION.

To the Editor.

Sir,—Having had the privilege for three or four years of being numbered among the invited guests who partake of the hospitality and obtain the publicity afforded by The British Journal Photographic Almanac; having also had the similar privilege in the *Photographic Yearbook*—a publication upon which, with true editorial catholicity, you have just bestowed a passing word of commendation; I naturally, and not without some measure of indignation, resent the insinuations of your correspondent, "T. H. W."

Of those eminent photographic firms to whom were consigned the reproduction of the portraits that erstwhile appeared in your pages, pray, which of them does "T. H. W." accuse of complicity—with having "dodged" the exemplars? There can be but one interpretation of that term. It is an utterly baseless accusation. Does "T. H. W." expect a civil rejoinder to that insinuation? Does he imagine that one at whom he sneers as a l'anglois will deal with him as a gentleman? The crude immaturity of his assumed literary qualifications is at once revealed by the designation he has applied to a personage who is merely one of George Colman's clever dramatic creations, but whom "T. H. W." styles "that arch-impostor, Dr. Pangloss."

The entire communication of "T. H. W." is simply a series of much-diluted sneers; and it is an old and obvious remark that "no one can refute a sneer." I refuse to follow your correspondent into the unwieldy topics into which he enters at such length. In your columns, devoted to photography, what concern have I with what the Tichborne Claimant did or did not recollect? Or with the statements, *pro* and *con*, of the prosecution and the defence? One single remark in that direction sufficiently meets the whole farrago. The identity of the Claimant was decisively attested, in terms the most precise and explicit, by the medical attendant of the Tichborne family, by the legal adviser of the family, by the banker of the family, by the clergyman of the parish, and last, but not least, by the mother who bore him. Of these five deponents, but one, the venerable and much-respected Hon. Treasurer of the city of Winchester, now survives. Thus, over and over again, might one set of statements be pitted against another. But are your pages the place for such mere bandying of assertion and counter-assertion? To such debates you would be fully justified in denying admission.

The style of attack in which "T. H. W." has chosen to indulge forbids my adding one word in defence of the views I have laid before the readers of The British Journal Photographic Almanac. Behind the mask of his three initials, "T. H. W.," may launch forth into whatever innuendo and insinuation it may please him. But, should he see fit to use only the language of a gentleman, or, in event of his having the courage of his

convictions, should attach his name to his diatribes, then, and only then, can I further notice him.

"Possibly," says "T. H. W.," in a concluding passage, "possibly, in the ALMANAC of 1893, *a sly sense of humour* may offer the apologist an open door." And for what set purpose, may I ask? "T. H. W." supplies his own version of the reply. For "prostituting photography to so base a use." How little recked your correspondent, when he penned this phrase, that there intervened but only that slip of manuscript between himself and the veritable personality that, by "*a sly stroke of humour*"—merely a lick with a wet tongue—had laid bare the most cruel and the most dastardly fraud that the villains of the plot had concocted, namely, the obliteration of the well-defined but much-maimed thumb from the original Daguerreotype.—I am, yours, &c., W. MATHEWS.

Clifton, Bristol, February 6, 1892.

GRADATION.

To the EDITOR.

SIR,—I am glad to find that this subject is attracting increased attention. May I point out a misunderstanding which seems to exist in the minds of some of your correspondents? It is assumed that, if two negatives of the same subject have their corresponding densities in the same ratio, they may be made to give identical paper prints. This is by no means true. A negative of four densities, 0, $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, cannot give an identical result with another of densities, 0, 1, 2, 3, although the ratio of gradation is unaltered. Not only this, but equivalent results cannot always be obtained from one and the same negative, as may be tested by printing in platinotype, silver, and developed bromide.

Some eminent authorities, it is asserted, disagree with Messrs. Hurter & Driffield; but they should do as these gentlemen have done, state their case in a manner that others may repeat, giving numerical results in support of their argument. I do not say that the matter is beyond dispute, but, in the face of the methodical, well-detailed experiments of Messrs. Hurter & Driffield, an opponent of their views should do more than vaguely quote the opinion of eminent but unnamed experts against them. Can anything more definite as yet be found? Captain Abney has two negatives, we are told, which disprove the position of Messrs. Hurter & Driffield. Will Captain Abney compare the opacities of a few corresponding parts of these negatives, and give the numerical results? It could then be ascertained whether these do not give a constant density, differing in each plate, due to stain, and the opacity of glass and gelatine, and a remaining series of densities due to reduced silver, obeying the law of Messrs. Hurter & Driffield. It seems to me theoretically possible to evade this law by adding a dyad bromide to the developer, thus partially destroying the latent image, and converting an over-exposed plate into a normally or under-exposed one; the great difficulty would be to so modify the developer as to obtain normal results from an under-exposed plate.—I am, yours, &c., R. C. PHILLIPS.

Arts Club, Manchester, February 7, 1892.

"OIL ON THE WATERS" IN PHOTOGRAPHY.

To the EDITOR.

SIR,—We have often heard of the effect of "oil on troubled waters," and I wonder if any of your readers have ever thought of applying it in a photographic way. I have, and with considerable success, as I think you will admit when I tell you what I have done, and the result as shown by the accompanying photograph.

I was called into the country, a few miles out, to photograph a house, group, and several views about the place. The house was situated on a hill at the end of a narrow valley. Down below was a pond, about half an acre in extent, but the draught up the valley covered the surface with ripples. In the distance this did not matter, but when I went down beyond the water to take a view looking up to the house, the ripples became a serious matter, and I determined to try the effect of the oil. knowing the place, I took the precaution to provide myself with a bottle of olive oil (about three ounces). After I had selected the point from which to take the view, and persuaded the cattle and sheep to keep within bounds, I put my plate in the camera, and threw the oil from the bottle, as much to the right as possible, *the direction from which the slight wind was coming*. With astonishing rapidity it spread over the pond, and, although I was fairly quick in exposing, I was not so quick as I ought to have been. However, there was a remarkable subsidence of the ripples, and the reflections in the water are discernible, which they were not before.

I should like to know if any of my brother professionals have tried the plan. If not, I would advise them to do so when any such occasion occurs; only let me advise them to use more oil—preferably linseed—and throw it on the water close to the side from which the wind is blowing, and I think they will secure good reflections even in windy weather. The wind, as you see, moved the trees but slightly, but the ripples were rather heavy, owing to the position of the pond.—I am, yours, &c.,

London-road, Ipswich, February 7, 1892. W. VICK.

NEWMAN AND ADAMS'S PLATE SHEATHS OR CARRIERS.

To the EDITOR.

SIR,—I notice in the current issue of THE BRITISH JOURNAL OF PHOTOGRAPHY the specification of a patent taken out by Messrs. Newman & Adams, for improvements in plate sheaths or carriers, the point of which appears to be the construction of such sheaths or carriers, with a "set back" to prevent contact between the backs of the carriers and the following plates. Will you kindly allow me to place on record, in case of any future necessity, that in the hand camera made by me and shown some years since at the North London Society, the principle of the "set back" was adopted, and called attention to. In that camera, which is tolerably familiar to many of the members, the carriers are simple sheets of dark cardboard, having ledges at bottom to support the plates, the outer edges being thickened by means of a narrow strip of cardboard glued on the back. This was seen to be necessary from the first to keep the plates clear of the rubbing which would otherwise have occurred in removing the carriers as the plates were successively exposed. The camera and carriers have now been in use a long while, and I find no need of any alteration, while, in a stereoscopic camera made (and shown) by me last year, an additional strip of card is glued up the centre of each carrier, to take the thrust from the back which would otherwise have a tendency to make the plates spring in the middle.

There did not seem to me to be, nor should I have thought of claiming any invention in the matter at the time, but I should be sorry if, for want of a word now, any of our friends who may have copied or thought of copying my simple carriers should be afraid of infringing any rights in the matter. It is, of course, possible that I may have missed the point actually claimed in the new patent, but I certainly fail to see any other.—I am, yours, &c., WM. BISHOP.

London, February 4, 1892.

PHOTOGRAPHING "THUNDERBOLTS."

To the EDITOR.

SIR,—I was at the Camera Club when Mr. Maskell projected on the screen a lantern picture of what he said was a "thunderbolt." It seemed to me that the "effect" was caused by a drop of something, possibly hypo, having fallen undesignedly on the plate, either before or after development, and which drop of something had produced slight chemical action on the film.

Those whose dark rooms measure three feet by three feet, or thereabouts, are not unaccustomed to these appearances; indeed, their difficulty is to avoid photographing "thunderbolts."—I am, yours, &c.,

London, February 8, 1892. VULCAN.

PAPER FOR WOODBURYTYPE.

To the EDITOR.

SIR,—We see in THE BRITISH JOURNAL OF PHOTOGRAPHY, February 5 ("Answer to Correspondents," A. Fraser), question as to where proper paper for Woodburytype can be obtained. We beg to inform you it is manufactured by the Rives people in France, and that we are their agents and keep a stock here.—We are, yours, &c., MARION & Co.

London, February 6, 1892.

MR. CIMABUE BROWN EXPLAINS.

To the EDITOR.

SIR,—In the hurry of writing you last week, as well as in my admiration for the frank and delightful outspokenness of your contributor, "A. R. S.," I was guilty of a slip of the pen which, in justice to those I was criticising, as well as to yourself, Mr. Editor, and myself, I ask your permission to correct. The last sentence of the third paragraph should, and was intended to, read, "Charlatan and impostor are the only words which correctly apply to *those given to* such practices *as A. R. S. denounces.*" The omission of the italicised words reduced the sentence to a meaningless and ungrammatical dig at nothing and nobody in particular.—I am, yours, &c., CIMABUE BROWN, JUN.

February 8, 1892.

NATIONAL ASSOCIATION OF PROFESSIONAL PHOTOGRAPHERS.

To the EDITOR.

SIR,—As it will not be possible for you to have report of our approaching Annual Meeting of members of the Professional Photographers generally on February 11 in your next issue, will you permit me to inform your readers that, in addition to the important firms named in previous lists, we have received accession and assent to the principle of "Trade Prices for the Trade only" from the following, amongst others:—B. J. Edwards & Co., Fry Manufacturing Company, Brooke Brookes (Bradford), Birmingham Photographic Company, Limited, &c.

I would desire to point out, with your permission, that the enlarger who supplies the outside public on the same terms that he supplies a *profes-*

sional photographer is not only robbing the man who has to get his bread and cheese by his retail business (and by *that alone*), but he is actually injuring himself in two ways.

The outsider would not, as a rule, object to pay a "gross" price (*versus* trade price) for his enlarged picture, and could not honestly expect to get his *single* order at *wholesale trade price*. Thus the enlarger would get the extra profit from those who prefer to send to him direct. Then the "enlarger" would no longer be the cause of perpetual friction and annoyance between the profession and the retail purchasers.

There are at least some 3000 professional photographers in the kingdom. Surely, then, standing regular orders (in quantities), and their continuous good will ought to have great weight with the "enlargers" as a matter of policy, common fairness, and honesty.—I am, yours, &c.,

D. J. O. NEILL, *Secretary.*

47, *Charlotte-road, Edgbaston, Birmingham.*

TYLAR'S FILTERS.

To the EDITOR.

SIR,—In final reply to Mr. Henderson, allow me to draw attention to his first letter, 22nd ult., testifying to the merits of a similar filter he had used for ten years, and then demurring to your readers how to make them. I am therefore astonished to see his letter in current issue stating "Filtration is a snare and delusion." What are your readers to understand by such paradoxical letters? If Hampshire water is pure as the weather is mild there, well, then, the residents of that salubrious county will not need the filter; but, at present, my experience is that the public are not satisfied generally with the purity of the water they get, by the numerous orders daily received for this "little friend of man."

Our large manufacturing towns are always complaining, and justly so, of the impurity of tap water, and only one day's use of the small filter, when reversed to cleanse same, will show what Britons swallow. Mr. Henderson desires to know where the novelty comes in. Surely this need not trouble him, for it would be difficult to prove anything novel to a learned and scientific gentleman. However, I claim the following advantages, which I think novel to the outside public who have little time to peruse scientific matters.

First, the convenience of adaptation. Secondly, the finish and neat appearance. Thirdly, the simple reversing and cleansing action. Lastly, the price is within the reach of the working classes whom I have catered for many years.

Like a great many expensive and large filters, it is very probable the Hampshire one complained about was not cleansed, and the consequence a slimy mass of water caused by passing through fungoid growths due to the decomposition of organic matters. With the new filter this is impossible as no organic accumulation can take place, hence no fungoid growths. The proof of this latest simple, effective, and economical novelty, I leave in the unbiassed judgment of your intelligent readers.—I am, yours, &c.,

W. TYLAR.

JENA GLASS.

To the EDITOR.

SIR,—You rightly assume, in your note on Jena glass in your last issue, that my remarks at Liverpool were not fully reported.

In reply to your note I had occasion to point out the impossibility of securing greater depth of focus and rapidity together in lenses by altering their distance or using new material, and this was my point when speaking of Jena glass.—I am, yours, &c. T. SMITHIES TAYLOR.

Heatherden, Kirby Muxloe, near Leicester, February 8, 1892.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

To the EDITOR.

SIR,—Will you allow me to announce that on Thursday, February 18, the above Association will hold their Annual Musical and Lantern Entertainment (ladies' night) at St. George's Hall, Champion Hotel, 15, Adelphi-street. Mr. J. Traill Taylor will preside on the occasion, and the programme, as arranged by the Committee, promises to be an unusually attractive one. Thanking you, Sir, in anticipation,—I am, yours, &c.,

THE HON. SECRETARY L. & P.P.A.

London, February 8, 1892.

HISTORICAL NOTES ON PHOTOGRAPHIC GLASS.

To the EDITOR.

SIR,—It appears to me that the time has now arrived when I may do some good by giving an historic record of the uses of glass for photographic purposes. When the Daguerreotype made its appearance, "Patent Plate Glass," was ground and polished on both sides; the size was 2½ × 2, and therefore the cost was not felt a tax of an oppressive character; but, after Goddard made it a great commercial success by quickening the exposure from ten minutes to ten seconds, it received an impetus, which naturally led to large sizes, such as 3¼ × 2¾, and then it rose to 4¼ × 3¼, and ultimately to 5 × 4. Talbot was beginning to attract attention with sensitive paper when size was no longer a difficulty; but the covering, when framed, became a serious consideration, costing, as it did, from 2*s.* 6*d.* to 3*s.* per super. foot. Ordinary sheet or blown glass in those days was of a very inferior quality, and looked not unlike hammered tin-plate. Crown glass was used also, but progressive sizes gradually crushed it out. Sheet glass gradually improved in quality, and occupied the field up to 1864. It was then I felt it possible to get rid of the objectionable sulphur that fixed itself on the surface whilst in process of manufacture. I commenced by laying down slate slabs, covered with fustian, and placed a square block, covered with felt half an inch thick, on the glass, to which a handle was attached, and kept a young man moving it backward and forward over the surface, sprinkling it with rouge and water. This, I found, entirely got rid of the sulphur, and hence the necessity of "Patent Plate Substitute" reduced the cost to 5*d.* per foot. The immense demand made it a necessity to turn it out in large quantities, and ultimately it rose to 70,000 feet in the course of a summer's work. I may state, steam machinery came into use to meet this demand, but this left me with a much greater difficulty to face; that was, to make blown glass optically flat. Now, I mastered both these difficulties by getting a Belgian glass manufacturer (who used wood only for making glass). This got rid of the coal sulphur, and allowed us to improve the process of flattening, whereby the glass so produced became optically flat, and a dozen squares, when placed one upon another, feel as if it was a block of glass. The natural tendency at present is for larger sizes, such as 12 × 10 and 14 × 10. I hear great complaints from professionals, that out of four they cannot rarely get two sufficiently flat, not saying one word of the immense breakage it leads to. This is a terrible loss, and disappointing to the consumer.

The conclusion I come to is, that unless the sensitive-plate maker enters into arrangement with glass manufacturers to make sheet glass with wood fuel, they will find celluloid taking up its place, and their occupation all but gone. I don't mean annihilation, for glass will always be used for portraits in small sizes, such as 5 × 4, &c., and in such sizes it may be looked upon as a bye-product; but large sizes must have more careful manipulation if it is to hold its own.—I am, yours, &c.,

Waverley, Alexandra-road, Birkenhead. JAS. ALEX. FORBEST.

Exchange Column.

**** No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Wanted to exchange, Dallmeyer's 1 B lens, for a long-focus copying camera.—Address, VICTORIA WORKS, Forest Hill.

Exchange, oval embossing press for cartes and cabinets, for head-rest for sitting or standing figure.—Address, J. W. C., 182, Carr-road, Sheffield.

Will exchange, 12 × 12 camera, with one single slide, with carriers for all sizes, and 12 × 10 landscape lens, for modern whole-plate camera, with one or more double slides and rectilinear lens, by good maker (approval).—Address, T. S. SISSON, Levens-park, Milnthorpe.

Wanted a light 10 × 8 camera, Acme preferred; will give in exchange whole-plate studio camera (by Fallowfield), one single and one double slide, nearly new, or studio chair, four backs.—Address, E. HOPKINS, Photographer, 31, Sydenham-terrace, Fratton, Portsmouth.

THE CAMERA IN THE ZENANA.—Photography has penetrated into the zenana. An enterprising native photographer has just established at Hyderabad, the great Mohammedan city in the Deccan, a studio for the exclusive use of the ladies of the zenana of the Nizam and his nobles. It is in charge of an English lady, and stands in the centre of a high-walled enclosure specially constructed to exclude the gaze of the vulgar male species. The proprietor is said to be doing a roaring trade, as the Hyderabad belles are not at all adverse to having their charms immortalised by the camera.

MR. W. I. CHADWICK, of Manchester, gave a talk on *Stereoscopic Photography* at 5, Chandos-street on Friday evening last, and illustrated his remarks on monocular and binocular vision with diagrams of the eye, and upon stereoscopic photography with the apparatus employed for the purpose. He passed round and explained his apparatus. A noticeable point was the simplicity of the working parts and the absence of screws, &c., which so often are a snare and a delusion at a moment of pressure. We learn that Mr. Chadwick will probably have stock of his special apparatus on show and sale at the Fry Manufacturing Company's show-rooms.

ANNUAL DINNER OF THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—This dinner took place on Monday evening in the Café Royal, Regent-street, about seventy members and friends, including ladies, being present. Mr. James Glaisher, F.R.S. (President), was in the chair. Appropriate toasts were given, the principal one—their retiring President—being given in a graceful and appropriate speech by Mr. W. S. Bird, who alluded to the services rendered to Science by the President, and then presented an illuminated address, signed by many of the leading members. Messrs. John Spiller and T. S. Davis responded to the toast of the Society; Dr. Lindsay Johnson for Scientific Applications of Photography; Mr. Payne Jennings for Art Photography; and Mr. J. Traill Taylor for the Photographic Press. Many members were absent through indisposition; but, notwithstanding this, the meeting was a highly successful one.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," *2, York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

W. M. Phillips, Southampton.—*Two photographs of the North German Lloyd s.s. "Eider."*

JAMES MEW.—Thanks; not at present.

G. A. G.—We do not know of such a solution.

J. ADAMSON & SON, C. WINTER.—Received with thanks.

R. M. C.—Percy Lund & Co., 21, Imperial-buildings, E.C.

R. C. D.—See our article in the ALMANAC on *Panoramic Photography.*

J. H. AINLEY.—Mr. J. Watney Wilson's address is 153, Tachbrook-street, S.W.

H. N. BUCKERIDGE.—See reply to C. J. Kirk and F. C. Beacham in last week's JOURNAL.

OPERATOR.—Apply to a firm of foreign booksellers, such as Trübner, or to Sell, of Fleet-street.

A. BADLAND.—The thing is quite practicable. Try Chadburn, of Sheffield, or Sharland, of Thavies Inn, London.

E. P. C. (Preston).—A suitable formula is: Caramel, 1 ounce; gum water, 1 ounce; methylated spirit, 1 ounce.

A. H. P. (Dublin).—We are unable to give the information desired, but a letter in English to the gentleman will serve.

OBERNETTER.—See Mr. J. Barker's formula for Gelatino-chloride Printing Out at page 786 of the ALMANAC for 1892.

J. WILLS.—The only album that we know of which fulfils your requirements is Zaenhsdorff's patent self-binding album.

JAS. EAKIN.—The *Journal of the Photographic Society of India* may be obtained of Messrs. Watkins & Osmond, 62, Ludgate-hill.

SOMERSET.—Mr. W. T. Wilkinson has published a work on the collotype process, which, we believe, is sold by Hampton, Judd, & Co., Farringdon-road, E.C.

H. B. A.—The extreme height of the building is quite immaterial; from thirteen feet the roof may be flat. At eaves eight feet six inches would be a suitable height. In line six of the previous answer the word "four" was omitted.

LUX.—Such a prism as you desire will necessarily prove expensive, provided you get it made specially. Your better way will be to build a fluid prism in accordance with the directions we gave on page 47 of the ALMANAC for 1871.

A WEEKLY SUBSCRIBER.—1. Use stiff starch, and well rub down. By keeping the mounts for some time before use the litho ink will lose its repellent character. 2. One is for looking at views, the other for reflecting them. 3. As far as is known.

F. BRYANT.—To ascertain the relative exposures required with the different stops, such as *f*-8, *f*-12, &c., square these figures, thus—64, 144, &c., and, knowing the time required for any one aperture, that for the others can be estimated proportionally.

T. R. CURTIS.—We have had no experience in tinting bromide enlargements with "aniline dyes." Some of the coal-tar colours are very fugitive, and others are more or less permanent. Standard water or oil colours are those to which our experience extends at present.

B. C.—If the metal vessel be thickly plated with gold or platinum, any, or all, photographic operations may be carried on in them. Copper vessels, plated with silver, may be used for emulsions. For ordinary operations porcelain, ebonite, or xylonite answers every requirement, and are more economising.

W. W. STEVENS.—1. The mottled markings are due to the plate not being rocked during development. 2. Yellow stains; these are caused by imperfect fixation before the plate was exposed to light. 3. Purple turbidity of the toning bath within an hour after making; contamination with foreign matter, which has reduced the gold to the metallic state. Probably a dirty vessel, or impure water.

M. K. (Leeds) sends drawings of a very complicated shutter, and asks if it, or any portions of it, have been made before, as he wishes to secure an incontestable patent for it.—On so important a matter as an "incontestable patent" we must decline to pass an opinion. Our correspondent had better place the matter in the hands of an experienced patent agent for investigation before lodging the specification.

COUNTRYMAN says: "I ordered three dozen plates from 'the stores,' and, when I received them, six out of the lot were broken, yet they were certainly carefully packed. Ought not the makers to make the loss good, as I feel certain the fault does not lie with the stores?"—Our correspondent has no claim on the makers, as he has had no dealing with them. If he has any redress, it must be from those from whom he purchased.

W. GRAHAM.—From the description of the state of the roof of the studio we should say the only effectual way of making it waterproof will be to have the whole of the old upper putty removed, and the rabbet and edge of the glass carefully painted. Then fresh putty, containing some white lead, can be applied. If the sash-bars are not sufficiently rigid to withstand a high wind, they should be strengthened by cross-bars, as any bending of them would cause the putty, when hard, to crack again.

R. W. SIMMONS writes: "There is just now a patented solution advertised that will cause gelatine films to come off the plates stretched to about double the original size. I have been using for a long time a fluid that will do this. Can the patentees prevent me using it now in my business, or restrain me from selling it, seeing I discovered it, and all my assistants knew of its power and composition, about twelve months before the patent was taken out or the advertisement published."—The patent will not prevent our correspondent from doing anything he did twelve months, or even a day, before it was applied for.

W. C. W. wants to know if a patent, the specification of which was recently published, will prevent his working a process he has had in use in his business for several years, or must he oppose the sealing of the patent at the present stage?—If our correspondent has had the process in open commercial use for years the patent, if sealed, will be invalid. There is no occasion to oppose the sealing. If the patentee were to proceed for infringement, all W. C. W. has to do is to prove prior use of the process. Probably, if the matter were brought to the knowledge of the one applying for the patent, he would abandon the application.

R. L. L. says: "Can you inform me, through the medium of your paper, what developer it is that produces a green negative? I have lately seen some very rich and luminous prints from such negatives, and was informed that they were developed with a potash developer. I have developed with the developer on p. 773 of the ALMANAC, but can only get the cold grey negative, similar in result to those developed with the carbonate of soda."—Without seeing the negatives we cannot reply definitely as to their green colour. It may, however, be that they are made on plates that yield "green fog" with the developer used. Green fog, though a defect, does not prevent excellent prints from being obtained.

PRINTER writes: "I should be greatly obliged if you could inform me through your paper the cause of such black spots as on example enclosed coming on sensitised paper, as I cannot think what is the cause of it. My system of sensitising is this: I work my bath at fifty-five grains, and float the paper from two and a half to three minutes, and then draw it up the side of the dish, so as to take as much silver off as possible, and then hang the paper over a line until dry enough to roll up. The sensitising dish is porcelain, and I also take great care in having my things clean, and never have any sweeping done, so as not to cause a dust. I have enclosed just a rough proof for your inspection."—The spots are caused by particles of something that reduces the silver in the paper to the metallic state. Whatever it is, it is not in the paper itself, as it appears to have come into contact with it either at the time or soon after sensitising, as the spot, though metallic, is only superficial.

PHOTOGRAPHIC CLUB.—February 17, *Public Exhibitions*, Mr. F. P. Cembrano, jun. 24, Monthly Lantern Meeting.

THE AFFILIATION SCHEME.—The delegates of the societies under the Photographic Society's Affiliation Scheme have held a first meeting. The rules were amended and referred to the Council.

THE MADDOX FUND.—This fund closes on March 31. Up to the present, nearly 300*l.* has been received or promised in this country. The American Fund, and the Continental Fund (which was organized at Southampton), so far exhibit considerable totals.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.—Next meeting, Tuesday, February 16, at half-past seven p.m., in Mosley-street Café, Newcastle. Subject of paper, *Platinum Toning on Matt-surface Paper*, by T. O. Mawson.

THE Richmond Camera Club's entertainment, postponed from January 15, in consequence of the death of the Duke of Clarence, will take place on Friday, February 19, at the College-hall, Richmond, at eight o'clock p.m. The invitations already issued will be available for the latter date.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—February 18, Lantern and Musical Entertainment, St. George's Hall, Champion Hotel. Tickets only. 25, Members' Open Night. March 3, *A New Enlarging Lantern without Condensers*, S. H. Fry. 10, *Collodio-bromide Emulsion*, A. Mackie.

THE *employés* of Messrs. George Mason & Co. met for a conversazione and dance in the Sauchiehall Rooms, on Wednesday evening, the 3rd instant. Thirty couples were present. Mr. Mason presided, and opened the entertainment with a short address. During the intervals songs were well sung by John Gibson, Mrs. W. W. Arthur, and Mr. Mason; readings were given in an artistic manner by J. C. Muir and J. N. Paton, and a piano and violin duet was played by Miss Mason and Mr. Thorpe Davie. The programme of twenty-two dances was concluded about two o'clock.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1659. Vol. XXXIX.—FEBRUARY 19, 1892.

PHOTOGRAPHERS AND THE TRADE.

If it has so far failed to attract the support of the bulk of those in whose interests and for whose protection it was founded, the National Association of Professional Photographers has made good its title to existence by gathering to itself such a fund of energy and vitality as to leave little room for doubt that, in the popular phrase, it has come to stay. The annual meeting was held in London last week, and a perusal of the report, which we give in another part of the Journal, will, we are confident, convince the reader that the Association has well weathered the tempests which all new bodies have to encounter in the early part of the voyage of existence, and that its continuance and success are rendered less problematical than they appeared to be a year ago. The objects of the Association are such as to compel the approval of all well-wishers of professional photographers, and they are championed by a number of men whose earnestness and directness of purpose constitute the best auguries for their ultimate success.

The objects in question are (*a*) to watch the copyright laws in so far as they deal with photography; (*b*) to bring legitimate pressure to bear upon manufacturers, dealers, enlargers, and others, in order to secure more equitable terms for professional photographers; (*c*) to obtain from the different fire insurance companies more just and liberal terms; (*d*) to assist the profession in maintaining a remunerative scale of prices; and (*e*) to watch legal proceedings against members, and to give assistance if necessary at the discretion of the Executive. This is a business-like and not too ambitious programme, in the drafting of which the Association has exhibited a most commendable moderation and wisdom, and, at the same time, has pointedly appealed for the support of every professional photographer without exception. It would be difficult for us, to whom the true interests of the profession are, we trust, known to be of the first regard, to adduce on behalf of the Association a more forcible claim for recognition at the hands of photographers than that which that body itself has furnished.

The annual meeting was not very largely attended, and only received the scantiest attention from London photographers; but, as if to make up for these drawbacks, it appears to have been marked by much enthusiasm and perfect unanimity, and to have secured the presence of many of those midland and north-country photographers to whose courage and zeal the Association traces its initiation. We congratulate our friends on their devotion, and, if for the present we have to deplore the want of spirit and gratitude shown by their London *confrères* in abstaining from either becoming members of the Association or putting in an appearance at the annual meeting, we have no misgiving that in the future no lack of appreciation awaits their well-meant efforts. In the mean time we hope that the London men will "come out of their shells," and disperse the suspicion that they are wholly indifferent to their own interests and to those of their profession, by joining the Association.

The record of the first year's work of the Association necessarily deals largely with the details of organization and other formal matters inseparable from its position as a new society; but for all that we are glad to learn, while the members must be pleased to know, that in respect of practical achievements the record is the reverse of a barren one. We gather that the Council have under consideration the copyright laws as affecting photographers, and are collecting such data as will assist them in taking action in the matter, and thus the first of the Association's objects is receiving due attention. As regards the second of the objects specified above, we approach, perhaps, the most burning question now agitating not only the minds of the members of the Association but also of innumerable other photographers. For some time past it has been alleged that many manufacturers and dealers, and those houses that undertake enlarging and other work for the trade, have been in the habit of supplying amateurs and the general public on the same terms as professional photographers. The contention of the latter is that this is an injustice to them, and, especially in the case of enlargements, it has aroused feelings of the acutest resentment. It is not difficult to understand those feelings and to sympathise with them, when we reflect that the supplying of enlargements forms a great part of the business of photographers which will be practically taken away from them if the firms to whom they entrust the work place them on no more favourable footing than the general public. For this reason objection is also taken to the appearance of trade prices in the advertisements.

The representations on the subject which the Council of the Association have made to the trade houses have been attended with so much success that only one inference is permissible, and that is, that the grievances complained of are of a perfectly legitimate character. It is, otherwise, impossible to account for the fact that a number of firms have agreed to make a distinction between the public and photographers in regard to terms of discount, &c. Briefly put, the photographer is in the position of a trader who buys to sell again, and from that point of view the argument that he is entitled to terms which will permit of him supplying the consumer at a profit is unanswerable. He is a species of middleman, whom to discourage is to deal a blow at the growth of photography in so far as it is promoted by an assiduous cultivation of sitters' orders for enlargements and other kinds of work which is put out to the trade. It is not impossible that, by ignoring the photographer, and supplying the public with work at the lowest, and often at cutting, prices, the ultimate effect will be to deter the

professional man from undertaking such commissions at all. In this case, who would suffer in the long run? Probably the trade houses as well as the photographers, for it is difficult for us to imagine that the former could exist on the support directly received from the public. It seldom chances so in general trade; and, the spread of amateur photography notwithstanding, we fail to see that it can in photography.

This is merely the fringe of one of the questions the Association has undertaken to deal with, and in which it and photographers generally have our sympathies and good wishes. What with bad business, amateur competition, the cutting of prices, and other causes, the lot of the professional photographer is just now not an enviable one. But we refuse to believe that it is not susceptible of improvement. The establishment of the National Association of Professional Photographers is an indication that photographers themselves are alive to the same persuasion. Conceiving the objects of that Association to be of the most laudable nature, and calculated to have as beneficial an effect upon photography itself as upon those whose profession it is, we wish it every success in its endeavours, and hope that it will immediately have a large influx of new members. The Executive, with the ex-President (Mr. Whitlock, of Birmingham) at its head, have, all things considered, given the Association a very good start.

PHOTOGRAPHY IN NATURAL COLOURS UP TO DATE.

Somewhat analogous to the process of Poitevin is that which we are about to describe, and which forms the latest outcome of investigation in the domain of heliochromy. The process now more immediately before us is that of Dr. Raphael Kopp, of Lucerne, Switzerland, a gentleman who, we are sorry to say, died a few weeks since, after having protected his process by patent.

Previous to giving details we shall point out the broad lines of similarity to Poitevin's process, some account of which we published so long ago as 1865. In both, a blackened violet or subchloride of silver paper forms the medium on which the coloured picture is produced. In both, this darkened paper is sensitised by being floated upon or brushed over with a solution of bichromate of potash, sulphate of copper, and a chloride, that of Poitevin being potassium, while Kopp prefers mercury. After drying, the sheets of paper are ready for exposure. Omitting for the moment a few details, both are fixed in a weak acidulous wash, Poitevin employing chromic acid, followed by a mercury and lead salt, Kopp adopting diluted sulphuric acid.

M. Kopp's process, as described in his specification, includes the preparation of the subchloride paper to which we have made reference. He salts Rives paper by floating for two minutes on a ten per cent. solution of chloride of soda, followed, when dry, by treatment for a similar period on an eight per cent. solution of nitrate of silver. The paper, upon being removed, is again transferred to the first bath for a short time. It is then washed by being placed in water for twelve hours, when it is treated by immersion in a bath of—

Chloride of zinc	0·15 gramme.
Sulphuric acid	2 drops.
Water	150·00 grammes.

The paper, which must have the layer or coating prepared as described up to now at the top, is placed in this bath, so as to be exposed to the light, but not directly to the sun, for it is necessary that the light should be diffused. The exposure lasts until the layer or coating has obtained a greenish-blue tint. The paper must not be exposed longer to the light, as the colour would easily become too dark.

Thus prepared, and well washed and dried between blotting-paper, this paper may be kept a long time.

To render this violet-blue "silver chloride paper," prepared exactly according to the above-mentioned method, suitable for producing all the colours, including white and black, he proceeds in the following manner: A solution composed of fifteen grammes of pure potassium bichromate and fifteen grammes of purified copper sulphate dissolved in 100 grammes of water is prepared. He crushes fifteen grammes of mercurous nitrate, so as to obtain a very fine powder, which is dissolved in as small a quantity as possible of water, rendered slightly acid with nitric acid. The solution of potassium bichromate and copper sulphate is heated on an open fire until it boils, and, while the mixture is stirred, the solution of nitrate of mercury is poured in. Finally the whole is put on the side of the fire, in order that the reddish-yellow deposit or precipitate may be formed, and the solution allowed to cool. This is filtered, and made up to 100 cubic centimetres. If the filtrate amounts to more than 100 cubic centimetres, it is reduced to that volume by evaporation. This solution keeps well, and must not be strengthened.

The blue silver chloride paper is next immersed in the liquid prepared as above, and turned over for half a minute. It is then drained and placed in a three per cent. solution of zinc chloride, shaking the vessel until the said paper has again turned blue. The paper is then well washed in running water. It is pressed between blotting-paper, and placed again for six minutes in the mercury bath. On being removed from this bath, and pressed between blotting-paper, it is ready to be exposed. The paper must not be allowed to dry before it is exposed, as the exposure has to take place in the damp state.

After the exposure, which varies according to the light and the season, and which is determined by a little practice, the yellow and green portions will be already well defined upon the paper, whilst the other colours, including the white, are covered with a yellow veil. For removing this the photograph is put in a developing bath. However, before this takes place the green and yellow colours, which are visible upon the photograph and could not withstand the developing bath, must be covered with a coating of varnish. When this coating is dry, the bath cannot act upon the varnished portions, and the colours will be protected at the said portions.

After each varnishing the layer or coating is heated over a fire, in order that the varnish may spread uniformly. The photograph is not introduced into the developing bath, which consists of a two per cent. solution of sulphuric acid, until the varnishing of the yellow and green portions, and the drying of the varnish has taken place. The photograph being left in this bath, the vessel is agitated, and the yellow veil disappears. All the colours, including white, appear in all their brilliancy. It is then washed rapidly in running water, and dried between blotting-paper.

For fixing and finishing the image, after the photograph has been taken from the developing bath and washed, it is again put in the mercury bath for five minutes, and thence transferred to the developing bath until the colours, including the white, appear again. From this moment no more washing is needed, but simply pressing. Next, the photograph is coated with a solution of gum arabic containing five per cent. of sul-

phuric acid; this solution of sulphuric acid and gum must be prepared beforehand, because a precipitate is formed, and the solution must be used clear. The photograph, coated with this solution, is dried by heat and finally varnished.

We have not yet had an opportunity of trying M. Kopp's process, but we see no reason why it should not answer. The analogous process of M. Poitevin, which we did try, gave heliochromic prints, the tints of which were quite decided, although we did not altogether succeed in fixing them by the method he suggested. It is fair to assume that M. Kopp has not left this matter in doubt. In reply to any utilitarian who may ask what is the use of such a process, we quote the electrical philosopher who, in response to a similar query, asked, "What is the use of a new-born babe?" We welcome every advance, although we may fail to at once discover its value. *En passant*, we may say that ordinary chloride of silver paper, darkened by exposure to light, forms a fairly good medium on which to try heliochromic experiments.

VARNISHING CELLULOID NEGATIVES

One of the minor questions of the day is that of the best varnish for celluloid negatives, which, for various reasons, require different treatment from those on glass. The thinness and flexibility of the material render it difficult, in the first place, to apply the varnish in the ordinary way by pouring, while a film of more than ordinary toughness is desirable in order to withstand the constant risk of cracking that the natural pliability of the celluloid involves. Add to this the fact—though this is of less importance—that the celluloid itself is more or less soluble in all the usual menstrua in which the gum resins are dissolved, and the necessity for a special varnish will be apparent.

In the case of glass negatives, the protective layer requires to be, in the first place, smooth and hard, while it, at the same time, possesses sufficient toughness to enable it to resist scratching under ordinary wear and tear. For collodion negatives these are the most desirable, or rather absolutely needful, qualities, and, if combined with the less important characteristics of freedom from colour and structure, may be said to constitute a perfect varnish. But gelatine negatives, though less exacting in the matter of hardness—the gelatine film itself being so much tougher than collodion—require the quality of toughness or, perhaps more correctly, elasticity in a higher degree, owing to the extreme sensitiveness of the gelatine film to damp. In the case of a collodion film the varnish penetrates into its substance, and, when dry, forms part of it; but with gelatine it is confined to a thin layer entirely on the surface, and subject to the constant action of expansion and contraction arising from the effects of damp upon the underlying film. When the gelatine is spread upon celluloid we require, as has been shown, flexibility as well as hardness and elasticity.

So far as ordinary spirit varnishes are concerned, the necessary hardness and toughness are obtained with comparative ease, and in combination with the minor desirable qualities; but it is the qualities of elasticity and flexibility that are more difficult of attainment. For these reasons, the preparation of a varnish suitable for collodion negatives is a comparatively easy task; while, as the early workers with gelatine plates will remember, it was soon found that the new films required a new varnish, and now, again, with celluloid as the support, we find ourselves face to face with fresh requirements.

The ordinary varnishes, composed chiefly of shellac and sandarac, which form an almost perfect coating for collodion negatives on glass, require considerable modification by the addition of toughening materials to adapt them to ordinary gelatine plates; but, when these latter are again changed for celluloid films, such varnishes are utterly unfitted for use, as no amount of toughening matter, short of what will otherwise spoil the varnish, will confer the necessary elasticity or flexibility, or rob the varnish of its tendency to crack and crumble when the negatives are even slightly bent.

Perhaps the best means of toughening any of the varnishes of this type is by the addition of a certain proportion of collodion of the kind used for enamelling purposes, the quantity being dependent upon the result desired, as well as upon the nature of the varnish, and what it will allow. If it be of a suitable kind for this purpose, an equal quantity of collodion, or even more, may often be added without producing a permanent precipitate of either resin or pyroxyline; but generally a much smaller quantity is allowable. The best plan is to try the varnish by making small additions of collodion to a measured quantity, shaking well after each, should any precipitation occur, until it is redissolved, and to continue this until the precipitate becomes permanent. In this manner it is easy to ascertain the maximum proportion of collodion that will remain in solution; but it is never well to work too closely to this maximum, owing to the structural inequalities that occur in the drying of such films; in fact, it is wise to have only so much collodion as will confer a fair degree of toughness and elasticity, and no more. In cases where the varnish shows an unwillingness to take up the collodion, the addition of a small quantity of camphor will generally increase its solvent powers.

A varnish of this kind was at one time extremely popular for gelatine negatives on glass, as was also a coating of enamel collodion alone. Both these serve almost equally well for celluloid, except for the trouble of applying them. The fact that the celluloid support is itself soluble in the menstruum of the varnish is of no direct importance, since the thick film of gelatine constituting the negative intervenes between them, but it becomes an item for consideration in connexion with the method of application. Celluloid negatives, even of small size, cannot be conveniently coated by pouring the varnish on and off, as with glass plates; they are too stiff, and seldom flat enough to float, and cannot be immersed on account of the solvent and softening action of the varnish on the reverse side. Consequently nothing remains but to apply by means of a brush or similar aid; but this, again, introduces the fault of unevenness of coating; besides which, the necessity of applying heat almost precludes their use.

Some of the slow-drying turpentine varnishes have been recommended for the purpose, but they are inconvenient in use, and not otherwise altogether satisfactory. The cold, drying "crystal" varnishes, with benzol as the solvent, have also been mentioned; but these seldom dry without a certain amount of "tackiness." Amber or copal, with chloroform as the solvent, are better, but still these only overcome the necessity for using heat.

Quite recently a slow-drying varnish, consisting of celluloid dissolved in acetic ether or acetate of amyl, has been spoken of, and seems likely to answer the purpose both in the matter of toughness and flexibility, as well as in ease of application, since in consequence of its slow drying it may be applied with a brush. But we fail to see what advantage the more expensive solvent has over plain methylated spirit which readily dissolves celluloid and forms a tough, colourless, and slow-drying varnish.

We can personally recommend this plan for using up spoilt celluloid films.

But none of these methods seem to us to equal an aqueous alkaline solution of shellac—the well known "water varnish"—which has also found favour in many quarters, and is indeed, if we mistake not, an article of commerce. It has the advantage of not dissolving the celluloid support, and so permits the negative to be bodily immersed in it, and, owing to its aqueous nature, it is absorbed into the gelatine film, and forms, as it were, a part of it. The natural toughness of the gelatine then adds to the strength of the protection, and, as the varnish when once dry is impervious to moisture, the compound layer is less affected by damp, and consequently not liable to swell.

The varnish itself is very easy of preparation. To a pint of water one ounce of borax is added, and dissolved by boiling in an earthenware or enamelled iron vessel, and, when dissolved, five ounces of bleached lac are added, and the boiling continued until solution of the resin takes place. The result will be a clouded, indeed somewhat thick mixture, which, however, may be strained through linen, and then set aside for a day or two until a flocculent precipitate falls and leaves the solution clear and bright. It may be finally filtered through blotting-paper if desired.

The celluloid negative, after careful washing, should be immersed in this varnish for two or three minutes, and then hung up to drain and dry. When surface dry, it presents a beautifully even surface, the excess of varnish being absorbed into the film.

The only fault we have found with this varnish, but one that will not be felt in this connexion, is that it does not bear exposure to heat well.

COLOURED PHOTOGRAPHS.

Before continuing our observations upon this subject, we may say we have been reminded that we have forgotten to allude to albumenised paper. We have not forgotten; but the uncertainty attaching to prints upon that surface is so notorious that we did not deem it needful to allude to them. However, let it be said that, although we have such prints in our possession that are as good now as the day they were printed—a score of years ago—we yet see around us so many pictures in an opposite condition, that it may be said that all silver prints are quite beyond consideration for any but the slightest and most inexpensive tinting.

The preparation of the surface for colouring the various kinds of permanent prints is a matter of importance. Ordinary size is excellent for enabling the artist to make the colour "take." If platinotype be the basis, a still better plan by some is considered the use of aqueous solution of shellac; without this, or a good body of size, the colour will not work freely, the texture being more like that of blotting-paper. By some artists, carbon prints are rubbed with fine glass paper, or with powdered pumice; especially is this advisable for pastel work. We have seen very beautiful coloured photographs in which the head alone has been printed in by either the carbon process or platinotype, the rest of the figure being drawn by hand, first traced from the enlargement. To do such paintings successfully requires a trained artist, not a mere "stippler," and such men like drawing-paper to work upon. To fulfil their requirements is not difficult by the carbon process. It is first necessary to make a solution of gelatine and chrome alum, and paint it upon the place where the head will come upon a sheet of Whatman paper. When it is dry, the small piece of tissue can be squeegeed to the place, and development carried on as usual. It is, however, necessary to put indiarubber cloth over the tissue before squeegeeing, to prevent injuring the surface. If the paper be abraded, washes of colour cannot be laid on easily, and a spotted effect would be produced. While the developed print is still wet, it is possible, by using a camel-hair pencil, to remove any objectionable portions. The print should then be well washed, to remove the small particles of tissue, and finally placed in alum water and washed. If all this be well done, we have a head in permanent photography, and for the rest an ordinary surface of drawing-paper, the chemical processes in no way interfering with the paper so long as it is not rubbed. It should be noted that Whatman paper, when wet, is very tender and easily torn.

For both carbon and platinotype prints it is necessary to be most careful to remove every particle of the last chemical employed, as the least trace of acid or of bichromate might prove ultimately of serious danger to the stability of the colours laid upon them. In fact, in each case, a final wash of ammonia would be advisable; for platinotype it would neutralise any acid left behind, and for carbon it would greatly facilitate the removal of the last traces of bichromate which, especially in thick paper, such as Whatman's, is rather difficult of removal, even as regards what is visible to the unaided eye.

It may be well to refer to ivory, though the demand is not very great for such pictures, which, perhaps, may be one reason why its treatment should be described. It will be useless to attempt developing a carbon print by the single transfer process direct upon the ivory. The material is liable to stain, it warps under the treatment, and the peculiar quality of this beautiful but expensive basis seems to be interfered with by the necessary prolonged soaking in water and treatment with chemicals. The photographer, therefore, should first develop his print upon the flexible support prepared by the Autotype Company, and then transfer it to the ivory by means of the usual gelatine and chrome alum solution. It may be here remarked that the quality of a print on ivory cannot be properly examined without placing a piece of white paper or other white surface behind it. Otherwise, even a beautiful print will look grey and washed out.

There remain now to be discussed photographs upon opal glass. For this purpose a glass with suitable surface is very necessary. If ground too coarse, no delicacy of workmanship can be put upon it; if too fine, it will work greasy, and allow nothing but fine stippling. Some artists prefer to have the print upon plain, unroughened opal, and obtain the proper surface by a special varnish applied afterwards, which dries matt, and gives a very agreeable tooth to the brush. There are few special details to be given as to the actual preparation of "opals" for painting upon. If bromide prints or enlargements are employed, every precaution ought to be taken in removing any possibility of hypo being left behind. When carbon is the method chosen, it affords considerable facility for modifying effects by working upon the soft film with a camel-hair pencil; especially is this so with vignettes, the edges of which are then easily graduated with great delicacy, the production of a well-graduated vignette in carbon being by no means an easy matter. But particularly on opal is the use of scraper and ink-eraser suitable; large effects can be produced by it alone, portions of the print removed, and all without in any way injuring the surface for the after-treatment, the consideration of which will occupy the next article upon this subject.

Photographers' Benevolent Association.—The Annual General Meeting of the Photographers' Benevolent Association will be held at 50, Great Russell-street, W.C., on Friday, February 26, 1892, when the report and balance-sheet for 1891 will be received, and the officers for the ensuing year elected. The report says that the income of the Association is derived from the generous contributions of the few, rather than from the thriftiness of the many, and thus its benevolent, rather than its provident, character still tends year by year to become more pronounced. We are sorry the Association is not better supported by the class for whom it was started. If that class was numerous nineteen years ago, how much more so must it be to-day, when the subscriptions of members for 1891 only reached the insignificant sum of 17*l.* 18*s.* 10*d.*

Colour Photography.—According to an evening contemporary, an influential petition is shortly to be presented to the Home Secretary for the release of E. W. Parkes, formerly a solicitor in the City, who is now undergoing seven years' imprisonment for fraud. Mr. Parkes' name in connexion with photography will be remembered as being associated with the Cellarier-Parkes Syndicate, a concern floated a few years ago to produce photographs in "natural colours."

Orthochromatic Photography.—In our last issue, in reviewing a work on this subject, we quoted a formula for rendering plates sensitive, not only to the yellow and orange rays, but also to the red. Now, a little consideration on the subject will show that plates sensitised for any special ray cannot be manipulated in that light. It would, for instance, be futile to attempt to develop plates treated with eosine in such a yellow light as might be permissible with ordinary plates, eosine being the special sensitiser for the yellow. In the formula alluded to, the sensitiser for the red is cyanine, and, as yet, no better has been found for that colour. Many persons who have prepared plates with cyanine, although they have rendered the red colours of the original well, complain that they are liable to fog during the development. May not this fog be due, when it has arisen, to the light of the workroom? It is obvious that a red light cannot be employed for plates sensitive to the red rays. If a plate could be made sensitive to all the rays of the spectrum, it is clear that it would have to be manipulated in absolute darkness.

Ordnance Survey Maps.—A Select Committee of the House of Commons has been moved for, and obtained, to inquire into the present management of the Ordnance Survey, and the best method of accelerating the production and publication of correct maps of Great Britain, and to report thereon. There is no question as to the desirability of expediting the issuing of the maps. At present it frequently happens that, by the time the map is published, the entire district it is supposed to represent has completely changed; particularly is this the case with the suburbs of large towns. The ordnance map is, however, a formidable affair, and, but for photography, it would be still greater. The maps are all produced by photo-zincography, and it may be justly said that nowhere is that process worked in greater perfection than it is at Southampton. By the way, it is somewhat a matter for surprise that photo-zincography is so comparatively little worked commercially, while photo-lithography is so extensively employed.

Fading of Gelatine Prints.—This subject—one of no little importance—was brought before one of the metropolitan societies at its meeting last week. It is an incontestable fact that some prints were exhibited which had undergone a marked change since they were produced—only a few years ago. It is also a fact that other prints were shown, made at the same time and, presumably, under similar conditions, in which there was no apparent alteration. This circumstance seems to prove that the fading is not due to the process itself, but to the method of working it. If all the prints had changed alike, there might be some apparent ground for suspecting the process. We have, on several occasions, called attention to the conditions necessary to be fulfilled if gelatino-bromide, or gelatino-chloride pictures are to be considered permanent, that is, according to the general acceptance of the term as applied to photographs. More than once we have referred to the directions as to manipulations issued by some makers of gelatine papers being very incomplete with regard to the care required in the different operations. This has probably been due to the fact of the introducer of the papers wishing to make the working of the material appear as simple as possible. It would be a matter for regret if a new and valuable process should receive a condemnation which is only due to the faulty system of working it.

Deterioration of Dry Plates.—It would appear from the report of the meeting of the Photographic Society of Philadelphia, given in our last issue, that the keeping qualities of American dry plates are not superior to those of our own country. Complaints were made that, by keeping, the plates became fogged at the edges, and in time the deterioration extended all over the plates, just as the majority do here. Much of this evil was attributed to the method of packing—which is the same as that almost universally adopted here—permitting air and noxious vapours to have access to the films. It will be within the recollection of our readers that we have more than once suggested that manufacturers of dry plates should pay some attention to the paper and the boxes in which the plates are packed. If they contain any impurities of a more or less volatile nature, they certainly will have an influence on the films with changes of temperature, when the plates are packed in the usual manner with strips of paper, leaving no air space between them. We have recently been using some commercial plates, the label of which shows that they were made in 1886, that were packed face to face, with blotting-paper between them, and they are quite perfect except at the extreme edges, where the paper did not quite cover the film. Mr. Carbutt, the well-known American plate-maker, at the meeting referred to, recommended parcelling the plates in waxed paper as a preventive of fogging at the edges. There is no question that, if plates were placed film to film, with nothing between them, and then wrapped in impervious paper, such as paraffined paper, they would be effectually protected from the atmosphere or any deleterious vapours. The only objection to this system of packing would be the danger of the films rubbing against one another. This, however, might be avoided by securing each pair of plates together by strips of gum paper at the sides. This method of packing is certainly worthy of trial with plates that have to be kept a long time before use or for export to hot climates.

DEATH OF MR. EDWIN COCKING.

We are sorry to learn of the death of Mr. E. Cocking, an event which occurred on Friday last, when he was suddenly seized with a fit of apoplexy, from which he never rallied. Mr. Cocking has been before the photographic public for a long course of years. In 1867 he became Hon. Secretary of the original South London Society, and contributed various papers, mainly having reference to the art aspect of the science. It is well known that Mr. Cocking, up till a recent period, was Assistant Secretary of the Photographic Society of Great Britain, a position he occupied for fifteen years, and every one connected with that body can bear testimony to the efficiency of his services during its annual exhibitions. He was educated at South Kensington as an artist, and was a frequent and, indeed, regular contributor to our pages and those of our ALMANAC, his last article being that on page 647 of the current ALMANAC, *Figure Studies in Photography*. Mr. Cocking was an affable and well-informed man, but had long been suffering from an increasing deafness, which incapacitated him from undertaking public duties, although he was entirely cured towards the close of last year. We are sure that our feelings of sorrow at Mr. Cocking's death will be shared by the large circle of friends he made during his long career in photography. He leaves behind him a record of unobtrusive usefulness which will long live in their recollections.

GRINDING THE EDGES OF PLATES.—II.

For a grinding slab for glass proceed as follows:—Take a piece of wood—it matters not what kind—of suitable size and plane it perfectly smooth, and as nearly flat as possible. My own slab consists of a piece of ordinary "flooring board" seven inches wide by a foot long. Having produced a clean, smooth surface, hold the board to the fire or place it in the oven until it is thoroughly warm, or as hot as the hand will bear, then brush over it an even coating of *thin* glue, free from lumps or inequalities. The wood may be allowed to absorb as much as it will of this first coating as a "priming," but it must be renewed before applying the emery. It is important that the glue should be thin, and thinly and evenly applied, and if freshly made so much the better. Take glue of the ordinary strength for carpenter's use and dilute it with an equal quantity of water and then to ensure an even coating, filter it.

Having spread this evenly, as described, over the surface of the wood, proceed to sprinkle or sift a plentiful supply of emery on to it, and extend this evenly by means of a sharp, side-long, shaking motion. When the surface seems evenly covered, throw off the surplus on to a sheet of paper, and tap the board sharply on the table to remove all emery that is not actually adhering to the glue; examine closely for bright, thin patches, where insufficient emery has clung, and if there be such sprinkle a little more on those places. It it still refuse to stick, it is because the glue has set too quickly. It must then be gently warmed, and the emery reapplied over the whole surface, as at first. When an even coating has been obtained, set it aside to dry, and when dry, or nearly so, brush it over quickly with another coating of glue, and reapply the emery as before, and this, when dry, may be followed by a third application, which will complete it.

It is of considerable importance what grade of emery to employ for different purposes. For simply grinding the edges of glass the coarsest that can be obtained may be used, say No. 30, or if No. 24 is obtainable so much the better. But a closer and much more durable surface is produced by laying a foundation of the coarser grain, and following that, when quite dry, with a second coating of No. 60. This seems to cut with the freedom of the coarse grain, and the smoothness of the finer. For fine grinding, or semi-polishing, the last coating should be "flour" emery.

The points to be observed are to have a perfectly even and thin layer of glue, and to keep it in sufficiently liquid condition to take thorough hold of the emery. This is the object of heating the wood, and of allowing its pores to fill themselves with glue before applying the emery. If this be not attended to the powder will rub off when dry, or come off in scales, from the want of adhesion of the glue to the wood. Then the drying must be carried far enough between the different applications to prevent the second coat of glue from moving the first. Perfect desiccation is to be preferred where time permits, as it adds very greatly to the durability of the coating. Heat should not be used in drying, or the glue will blister, and subsequently scale off.

Such a slab as that described I use constantly when cutting plates in the dark room, or when I find they need it. The plate is held at an angle of forty-five degress, and each of the eight edges is passed lightly, but firmly over the slab, at a slight angle with the direction of the edge. Heavy pressure is needless, and only tends to cause "chips," though there is no serious danger of this with a properly prepared slab. The plates must of, course, be dusted with a camel-hair brush before placing in the slides.

It is not possible to do much in the way of grinding the edges of the unexposed plates, nor is it desirable to attempt it; but, after the completion of the negative, it will well repay the operator to remove any inequalities of a serious character that may have been left by the cutter. This is easily and quickly done on the emery slab without the slightest risk to the negative, and much to the advantage of the digits of the printer.

Where the means are available for utilising the services of an emery wheel made on this principle, it will be found useful for a variety of purposes besides tool grinding, as, for instance, in grinding and polishing glass, cutting shapes of either straight or curved outline, or, in skilful hands, glass bevelling. Indeed, I have found these wheels one of the most useful additions to my workshop, as with ordinary care if kept dry—which is important—they last for months without renewing, and when worn to a "glaze" only require regluing and dusting. In fact, the older they become the better they are, on account of the greater homogeneity of the foundation. Should the surface by any accident become chipped or scaled, as from too heavy pressure of a point tool in grinding, or from damp, the whole of the emery may be removed and saved by soaking first in cold and then in hot water, when the wooden foundation is in a condition for re-coating.

W. B. Bolton.

ART AND GENERAL NOTES.

Photo-Mechanical Exhibition.—At the Museum of Fine Arts, Boston, U.S.A., there is just now a collection of examples, illustrating the technical methods of art reproduction with reference to photo-mechanical printing processes, and their development, for producing printable blocks and plates. Such an exhibition in London would, we are sure, be welcomed by many.

An Artist's Charity.—A novel way of increasing subscriptions at charity dinners is to be adopted by Mr. David Law, the etcher, who has undertaken, at the Artists' Benevolent Institution dinner in May next, to present a signed proof of an etching to all subscribers of a guinea and upwards on the Fine Art Society's list. The etched plate is to be destroyed after the dinner. Here is a hint for the Photographers' Benevolent Association, when it is in need of funds. Hold a dinner, and give signed prints from a negative, say, by Dr. Emerson, to all subscribers of so much, and then destroy the negative.

The Woodcuts of Gothic Books.—At the Society of Arts recently, Mr. William Morris, the poet, read a paper on this subject, in the course of which he said, "All organic art, all art that is genuinely growing, opposed to rhetorical, retrospective, or academical art, art which has no real growth in it, has two qualities in common—the epical and the ornamental; its two functions are the telling of a story and the adornment of a space or tangible object." There is much in this that applies not remotely to photography. Mr. Morris's examples were illustrated by means of the optical lantern, and the lecture was a learned criticism of ancient and modern methods of book-illustrating.

Art at the Proposed Photographic Institute.—We agree with Mr. P. H. Newman who, apropos of some remarks on this subject which appeared in our leader last week suggests that, as we say, every one has his own pet idea on the subject of art in relation to photography, many must of necessity be wrong. But granting this and also his deduction that the greater the reason for art being included in a projected curriculum, we not only feel that the subject would be outside the scope of a technological institute, but we are also in considerable doubt as to whom we should look to for the office of putting the many that are wrong right. What *is* right?

Photography at Chandernagore.—All the way from Chandernagore, we lately received a letter from Mr. Bankinchandra Mukerji, the honorary secretary of the Amateur Photographers' Union. Accompanying the letter were several cards embodying good wishes. They were highly coloured representations of the goddess Sacti (Power) under the different forms assumed by her on different occasions. The letter also contained a photograph of the chief Hindu goddess, Durga, taken by a beginner, whose reward, it appears, is the satisfaction of getting a specimen of his photography to England. The Amateur Photographers' Union of Chandernagore only possesses two cameras. Its members seldom see the photographic papers, and they "stare with mute wonder when they read some of the marvels in them when chance takes them a copy." They lament the absence of somebody competent to instruct them in the various manipulations described! The excellent picture of the Hindu goddess above referred to convinces us that this is pure satire—if not sarcasm.

THE PHOTOGRAPHIC SOCIETY'S LECTURES.—III.

PHOTOGRAPHY AS A BRANCH OF TECHNOLOGY.*

A Branch of Technology of the First Order.

The True Cause of Technical Education Threatened.

The danger ahead which threatens the true cause of technical education appears to me to be this: The resources of the country are being too much frittered away in the multiplication of machinery for imparting elementary instruction, and the higher specialisation, which alone will save us in the end, is being crippled thereby. The elementary groundwork must be laid, and this work, as far as it is being done, cannot be done too well. But it is absurd to suppose that we shall recover our lost position in any branch of industry by scattering broadcast a knowledge of elementary science, and there leaving matters to stand. A technologist is nothing—at least in any of the subjects with which I have had connexion—unless he has the means of superadding more advanced specialisation to his general grounding. So far as the chemical industries of this country are concerned, a few highly trained specialists are worth more than an entire army of elementary certificated teachers or prize-winners. We are expending so much energy over our foundations, that there is but little left for raising the superstructure. We are arming our industrial fighters with weapons which are as pop-guns compared with the heavy ordnance of our competitors. Unless those who are responsible can be made to see that the elementary training in general principles is, in a large number of subjects, quite useless, unless the higher specialisation is equally well catered for, we shall be no better off in these branches of technology than we were before. The elementary training bears to technology the same relationship that the tuning of the instruments does to the overture. There is a great deal of twanging and blowing going on all over the country, but, as yet, comparatively few indications of a finished performance. There is enough money in the hands of the County Councils at the present time to support technical institutes adapted to local requirements on a scale which would bear comparison with the polytechnics and technical high schools of the Continent. If each county, or group of counties, had its central technical institute, manned by competent specialists, then the elementary training might bear real fruit, and we should look forward with greater hope to the result of the campaign on which we have entered. It is not difficult to see how the fight will end if we persist in blazing away with this elementary small shot in response to the ponderous missiles of our industrial competitors.

Out of the haze of generalities which I am afraid I have been led to inflict upon you, the central idea concerning the proposed action of this Society I hope begins to loom with a more or less definite form. It is not for you to add to the general tinkling of small bells, but it remains for you to bring together a strong staff of expert ringers who can give us a good loud peal on the chimes. You will, I hope, sooner or later, set an example in technical education in your own subject—which so admirably lends itself to the purpose—which shall act indirectly on all related subjects, by showing how much of the real work of technology begins after the elementary and advanced training have been completed. The instruction imparted under the existing arrangements is good as far as it goes, but from your point of view it must be regarded as the means of supplying the raw materials out of which the technologist of the future is to be moulded. It is not your province to assist in multiplication of the elementary classes, but to set the seal of efficiency on the existing organizations.

A Splendid Opportunity before the Institute.

I should have but little justification for addressing you as I have, did I not feel what a splendid opportunity lies before you for raising the level of at least one important branch of technology. Still less should I be justified in responding to your invitation did I not offer some suggestions which may be of use in furthering your object. The Photographic Institute, such as we desire, would be an establishment thoroughly equipped for the best practical instruction, well provided with appliances for carrying on research in every department of the subject, and having attached to it the most competent specialists in every branch. The staff need not be numerous at first; a chemist, an optician and physicist, an expert in photo-mechanical processes, and an artist would represent the chief departments. Your committee or governing body would know the right men to select; if they cannot be found in this country, you may have to go abroad for them. This course may appear ignominious; but, if it has to be adopted, so much the better, it will bear practical witness to the necessity of having the means of raising such men in our own country. The ideal institute may be a slow growth, but every effort should be made to establish it. The Photographic Society has already taken the initiative by proposing an affiliation with kindred Societies.

Concluded from page 108.

This scheme should be energetically pushed forward, and every means adopted for urging the importance of the claims of photography to have a recognised technological centre. I venture to think that an impetus would be given to the movement if representatives of the Camera Club, the Photographic Convention of the United Kingdom, and of the numerous photographic Societies of the metropolis were invited to another conference, such as was held last year, but with the special object of forming a joint committee, under whose authority a further appeal might be made for public and private support. If only a moderate fund could be raised at first, operations might be commenced. Surely the numerous firms which have come into existence through the general introduction of photographic processes, and the large body of wealthy amateurs who practise the art as a pastime, might be sufficiently interested in the movement to give it their support.

It only remains now to bring these suggestions to a practical issue. We are such a very practical nation that, unless something tangible is offered, the foundation of the Institute may be indefinitely delayed; as yet, there is nothing of the kind in existence—there is no organized work being done that appeals directly to the patriotism and to the pockets of those to whom you may legitimately look for assistance. But elementary photography is being taught in connexion with technical schools and classes all over the country. A good beginning might be made if under the auspices of the joint committee a few first-class specialists were enlisted and authorised to give short courses of demonstrations to those affiliated societies, or in those centres which desired to receive such instruction. The local centres might fairly be asked to make the necessary arrangements and to bear the small expense of local organization; the fund raised by the joint committee would be well spent at first in defraying the costs of a few special lecturers. You may have some difficulty in laying your hands on the right men for this work; I need hardly remind you that the whole success of this initial movement depends upon your sending only the most highly qualified specialists. You must have men who can teach the teachers, and convince practical photographers that underlying the practice of their art are broad scientific principles, which it is their interest to know something about. These preliminary peripatetic courses must be regarded in the light of missionary efforts, having for their object not the multiplication of photographic operators, but the awakening of the elementary and advanced student to the higher aspects of their subject. It is desirable to have this function of the lecturers well understood at the outset; the experts who are entrusted with this work will know well enough that it is impossible to make a technologist out of a student, however enthusiastic he may be in his subject, simply by giving him a course of lectures.

The Institutes of Berlin and Vienna.

If the system of itinerant instruction which I have suggested can only be fairly started, even on a small scale, one important function of the Institute will have been inaugurated. It will have a claim upon the practical educationalist as a teaching body; it will appeal more specifically to the promoters of technical education, and to those public bodies which have voluntarily or by Act of Parliament identified themselves with this movement. It is certainly discouraging—I may say discreditable—when we see the magnificent scale on which the photo-technical institutes of Berlin and Vienna have been founded and equipped, that in this country, whatever the importance of the subject, public recognition and support come only after success has been achieved by private enterprise. I am afraid you will have to reckon with this national characteristic, which, although retarding advancement in many directions, is so far good that it calls forth the most strenuous exertions to ensure success at the outset of every new movement. Upon the success of your first small undertaking will depend the larger ultimate success which we all look for.

One other suggestion occurs to me which may help to strengthen your hands. I have said that instruction in photography is already being in many technical schools; this instruction is more or less of an elementary character. It seems feasible to combine with the proposed courses of special lectures a system of inspectorship which might be carried out by the same staff. Your lecturers would be recognised experts, capable of advising such schools as to methods of teaching and of co-operating with local centres in the selection of the most highly qualified teachers. I am sure that most centres would be only too glad to avail themselves of the knowledge and experience thus placed at their service. If you begin operations on these lines at first—if you can carry on this combined system of skilled teaching and inspection successfully for a few years, your claim for permanent establishment and endowment as a Photographic Institute cannot but receive that support from public bodies to which your educational efforts will have entitled you, and which in other countries is given by the State.

Raphael Meldola, F.R.S.

ELEMENTARY NOTES ON PHOTOGRAPHIC LENSES.

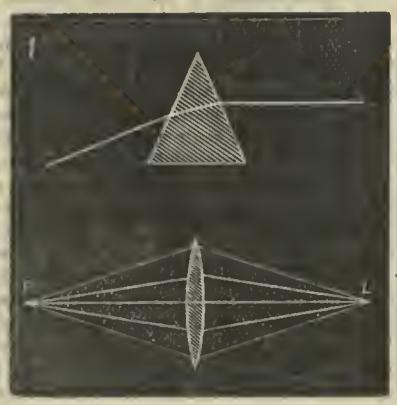
[A Communication to the Polytechnic Photographic Society.]

An essential qualification in a skilled workman is that he should thoroughly understand his tools, and be so well acquainted with the capabilities and characteristic or distinctive qualities of each one that, whatever work he may be engaged upon, he will instinctively select the most suitable for producing the desired result.

It is not intended to ask your attention to an abstract or advanced technical essay, but rather to a consideration of those elementary principles and facts relative to the construction and action of photographic lenses, and their bearing on practical work, that should be familiar to every photographer. The lens being his principal tool, a more perfect knowledge of its powers and properties is of the highest importance.

Refraction.

It is a familiar fact that the direction of a ray of light is changed or bent by passing through a prism, this bending being called *refraction*, as shown in diagram 1. Now, if a piece of glass, having its surfaces ground to form



parts of a sphere, be substituted for the prism, as in the lower figure in the diagram, it will be seen that its action is similar to an infinite number of prisms, all points at the same distance from the axis refracting the rays to the same extent, and all other points refracting to an extent proportionate to their distance from the centre, so that all rays from the same source of light, L, are refracted, and meet at a point on the opposite side of the lens, P, this point being called the *focus* for that ray.

In all diagrams of principles, the lens is drawn very large, to render the illustration plainer. It will be seen from this that each point in the image is the apex of a cone of rays, the base of the cone being the working diameter of the lens; and a lens is capable of transmitting an infinite number of such cones of light, and bringing each to its own focus independently of the others, each preserving its own character, direction, intensity, and individuality intact.

The amount of refraction is determined by the curves of the lens; consequently, the greater the angle at which the rays enter, the more acute will be that as they leave, so that, the greater the distance of an object the nearer the lens will the image of that object be formed.

In Diagram 2 an object at O^1 has its image at F^1; while one at O^2, nearer the lens, projects an image at F^2, farther away.

Foci of Lenses.

When the focus of a lens is given, it is always the focus for parallel rays or those proceeding from an object at a very great distance, this being the nearest plane to its surface at which a lens is capable of forming an image. This is generally called the equivalent focus, and, being known, the distance at which nearer objects are sharply defined is easily found.

If F = equivalent focus;
D = distance of object from lens;
I = focus of that object or distance of image from lens;

$$I = \frac{F\,D}{D - F}.$$

Example: Focus of lens, 10 inches; distance of object, 90 inches.

$$I = \frac{10 \times 90}{90 - 10} = \frac{900}{80} = 11\tfrac{1}{4} \text{ inches.}$$

When an object to be photographed is placed at a distance from the lens equal to twice its equivalent focus, the image is formed at exactly the same distance, and is the same size as the object. This gives a simple method of ascertaining the focus of a lens, the only drawback being the necessity for a camera that will extend to nearly twice the length necessary for ordinary work with the same lens. Adjust the camera until the image is the same size as the object itself; measure the distance from the ground glass to the object, *one-fourth* of which is the equivalent focus of the lens.

When the camera will not extend sufficiently for this, the same principle may be applied, though the method is rather more complex. Focus and measure any convenient object, arranging so that the image is a certain proportion of the size of the original, and carefully measure the distance from the ground glass to the object.

F = equivalent focus;
D = distance of object from focussing screen;
R = ratio of size of image to object:

$$F = D \div \frac{(R + 1)^2}{R}.$$

Example: An object is focussed, and the image is one-eighth full size, the distance between the image and the ground glass being 101¼ inches. By working out as shown on the board, the focus of the lens is found to be 10 inches.

$$F = 101\tfrac{1}{4} \div \frac{(8 + 1)^2}{8} = 101\tfrac{1}{4} \div \frac{81}{8} = 10 \text{ inches.}$$

As so much in the intelligent use of a lens depends on knowing its focus, a photographer should carefully measure each one in his possession. For those who prefer the most simple methods possible, a roughly approximate result may be obtained by focussing a distant object, and then measuring from the ground glass to the lens itself if a a single, and to the stop-slot if a double, combination.

The size of the image of an object at a given distance is approximately proportionate to the focus of the lens used; a lens of ten inches focus will give an image about twice as large as one whose focal length is *five* inches.

The distance beyond the equivalent focus that the ground glass has to be extended to produce a sharp image of any given object is a fraction of the focus expressed by one figure less than the multiple of the focus that represents the distance of the object. For example, if a sitter were placed thirteen feet in front of a twelve-inch focus lens, this, being thirteen times the focus, would necessitate the ground glass being extended one-twelfth of twelve inches—*i.e.*, one inch beyond its position for distant objects—while the same distance from a six-inch lens, being twenty-six times the focus, would require one-twenty-fifth of six inches, or rather less than a quarter of an inch extension, the scale of the images being one-twelfth and one-twenty-fifth full size respectively.

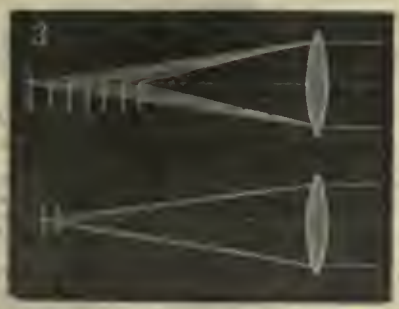
The extent to which any object is out of focus when another is sharply defined increases as the square of the focus of the lens, the example just given showing that for the same object a twelve-inch lens required four times the extension beyond the equivalent focus that the six-inch lens necessitated.

This will illustrate the limited practicability of *fixed focus lenses;* by which is meant those that, without any extension of the ground glass, will define, far and near, objects sharply, which is, theoretically, an impossibility; but, when lenses of very short focus are used for subjects at a moderate distance (this is such a large multiple of the focus) that the corresponding fraction is such a very small quantity, that, the lens being carefully focussed for an average distance, all other objects likely to be included in "snap shots," will be sufficiently sharp for practical purposes.

Dispersion.

A ray of light, passing through a prism or a lens composed of a single piece of glass, is not only refracted, but also *dispersed*, or divided up into its elementary colours, each colour ray being brought to a focus at a different point, and in the following order from the lens:—red, orange, yellow, green, blue, indigo, violet, as shown in diagram 3. For rendering the illustration clear, the distance between the extreme points is greatly exaggerated, and would be more correctly represented by the lower figure.

The rays to which our eyes are most sensitive are the yellow, which have very little effect on an ordinary photographic plate, this being considerably more sensitive to the blue than to any other; so that, if an image formed by such a lens were sharply focussed in the ordinary way, and a sensitive plate exposed, the resulting negative would be blurred or out of focus, owing to the chemically active image being situated at a



different plane from the greatest visible sharpness. Different kinds of glass do not *refract* and *disperse* to the same extent, so that, by a skilful optician combining two pieces of sufficiently varied refractive and dispersive powers, the action of one is corrected by the other, and the chemical and visible images are made to coincide, and such a lens is said to be *achromatic*, or free from colour dispersion.

This combination to form one lens must not be confused with a double or compound lens, having one element at each end of a tube. The two glasses are cemented together in optical contact, as in diagram 4, and to an ordinary observer appear to be one piece only. A single lens is such a cemented combination, while most compound lenses consist of two similar elements mounted at the opposite ends of a tube.

A simple or non-achromatic lens is capable of forming a photographic or chemical image if suitably focussed. When the greatest sharpness is obtained on the ground glass, it should be moved slightly nearer the lens, the exact distance being one-fourteenth of the focus.

CARBON PRINTING.

[A paper read before the Birmingham Photographic Society.]

I do not propose to occupy your attention this evening with any long description of carbon printing, but rather to proceed as soon as possible to the *practical* part of the matter, because I am aware that you have carbon experts as members of your Society, and have not long since had a demonstration on this subject; but I think there may be some possible differences in treatment and method, and that my method of working on smoothed opal glass may be a portion of this subject new to you.

I fear it may be thought an old story, and to some extent an obsolete process, for producing photographic printing, and it is older in point of date than the platinotype, bromide, or gelatino-chloride processes, but I think it can hold its own with any process in existance in the important points of delicacy and gradation of tone, and especially as regards the richness and transparency of the shadows.

On this particular point I think carbon surpasses all other processes. You know that it is easy to bring the delicate detail of the darker shadow, and in a dense deposit, when printing in bromide or platinum, but the peculiarity of the carbon printing is that, no matter how deep the shadows may be, if there is fair detail in the negatives it will show in the prints, because the shadows consist of varying thicknesses of gelatine tissue, and there is always atmosphere and transparency in them.

I would call your attention for a few minutes to the more conspicuous points of the process as regards its advantages and disadvantages, compared with other known processes, and I take it for granted that you all know the *rationale* of working in carbon tissue.

Advantages of the Process.

I have known the working principle of the process for many years past, but I always had an idea that it was a dirty, messy, sloppy process, which required an unlimited supply of hot water, and I purposely neglected it, because I could not see my way to make any provision of such supply. But, after trying pretty well all the known printing methods, and being dissatisfied with most on account of the want of permanency of some, and the difficulties attendant on the imperfect working of others, I resolved at last to see the carbon process as worked by the Autotype Company of London, and the simplicity of it was so striking that I at once took it up, and I think it combines most of the good points one desires in a photograph, and avoids the disagreeable after-work of long washing and soaking of prints to eliminate any salts left by fixing agents.

The advantages of carbon are, first, permanency. There cannot be any doubt on this point, if care is used in adding pigments of undoubted permanence to the gelatine tissue, and there are so many absolutely reliable pigments available that we may dismiss all anxiety on that point. The film of gelatine in which the colouring matter is suspended is not only rendered insoluble in very hot water by the action of light, but is afterwards subjected to the tanning action of alum, so that it may be considered to be doubly treated in a way to render it permanent, as a means of enclosing and preserving the colouring matter which forms the picture.

Secondly, there is no need for any inspection of the print during exposure in the printing frame. The time is ascertained by an actinometer, consisting of a strip of sensitised silver albumenised paper compared with a tinted ground, and therefore there is no risk of fogging the print by repeated examinations of its progress in a weak light. This may possibly be thought an objection and a source of difficulty; but, though it requires the experience of a first print from each new negative to determine the correct actinometer exposure, when it is once determined and a memorandum made of it, all future printing from that negative becomes a certainty, and you may produce without mistake any number of after-prints so long as you work accurately by the actinometer.

I always expect to have only an approximately correct print from the first piece of tissue exposed on any new negative, as no one can tell by examination what the vagaries of every negative may be the first time of using; it may require longer or shorter exposure and more "blocking out" of certain parts than at first sight might be expected. Therefore I put it down as one of the disadvantages of the process that the first print from a new negative must be regarded as a tentative proceeding, and the subsequent prints from such negative must be guided by the experience gained from the first trial.

As soon as I know the correct actinometer exposure, I write it on the back of the negative in the clear rebate margin with a writing diamond, and it is always at hand for reference, and it may be relied on as an unfailing guide for future work.

Thirdly, comfort and convenience in working. All who have printed by bromide or alpha paper will have felt the discomfort of having to work in a red or orange light, and the difficulty of estimating the exact pitch to which development has arrived, and the correct time to stop; but in carbon work it is widely different, the tissue, when moistened for development, becomes comparatively insensitive to light, and it is possible to work in a fairly good diffused daylight, or by a very strong gaslight, without risk of fogging the image, and it is an immense comfort and convenience in judging of the critical state of the print to be able to use a strong light and see so perfectly what one is doing.

Fourthly, convenience in obtaining materials. The tissue can be had freshly sensitised twice a week from the Autotype Company, and travels well by parcel post sent out in cut pieces of the exact size required for any negative, and it is ready for use at once, or you can have it sent in rolls, and cut it up yourself; but in this state I find there is some danger of cracking the face of the film in unrolling it ready for cutting up, and the system of cut pieces is most convenient.

Some Disadvantages.

The chief drawback to carbon tissue is that after sensitising it will only keep in good working condition for a short time, say, about twelve or fourteen days, if kept in a dry condition, so that it is advisable to use it up as promptly as possible, or to order only as much at one time as can be used up with any series of negatives within a fortnight; but it is just here that the convenience of obtaining it in cut pieces twice a week comes in, as the postage is light on it.

I have some experiments now in progress by which I hope to find that it may be kept longer, if not indefinitely. It has been stated that gelatine, when sensitised by bichromate salts, becomes insoluble in course of time only in the presence of moisture; and it would seem feasible that, if all moisture is extracted by storage in a chloride of calcium tube, such as is used for a platinum paper, it might be expected to remain in good printing condition as long as dryness is maintained. If so, it will be a great convenience to be able to keep tissue longer; if not, we shall be in no worse position than at present.

Of course, such desiccated tissue must be allowed to absorb moisture to a normal extent by being placed in a dark and damp cellar for a short time before use in the printing frames; and, as it is very hygroscopic, it will rapidly absorb sufficient moisture.

The only disadvantage of a serious nature in carbon printing I am aware of is the action of the skin of the solution of bichromate, which has a known poisonous property if too long in contact with the hands. The warm water necessary for the solution of the gelatine in development renders the skin very absorbent, and the salt, after a time, creates considerable irritation, resembling 'chapped hands' due to cold weather, and in aggravating cases it strongly resembles 'eczema,' with great itching and smarting of any cracked portions of the skin. On questioning the *employés* of the Autotype Company on this point, I found considerable variation; some in constant use of the tissue were not affected by it,

others were attacked in the way indicated; it appears to be partly constitutional tendency to it or otherwise. In my own case, I worked the process for nearly a month before I found any inconvenience; then the irritation commenced, and I had to leave off for a time, and by the use of vaseline pomade it soon ceased; I then adopted stout indiarubber gloves for use in development, and have not had the least trouble since—in fact, the use of indiarubber gloves is pleasant and beneficial, as they act like a Turkish bath, and keep the hands in nice order, if washed in soap and water after work. I therefore strongly advise any one who takes up carbon printing to avoid the unpleasant consequences of contact with bichromate solutions, by the use of indiarubber gloves.

GEORGE BANKART.

(To be continued.)

NATIONAL ASSOCIATION OF PROFESSIONAL PHOTOGRAPHERS.

THE first annual meeting of this Association was held at Anderton's Hotel on Thursday, February 11, the President, Mr. H. J. Whitlock, in the chair.—The attendance, if not large, was representative, members from Leeds, Sheffield, Hull, Birmingham, Manchester, Lincoln, London, and other large towns, being present.

The PRESIDENT, in opening the proceedings, gave a history of the Association since its inception, and said that throughout there had been great unanimity among the country photographers. They had now come to London to hold out the right hand of fellowship to the London photographers, among whom, he had been told, some jealousy existed. Whether they succeeded or not in their endeavours, they would have the satisfaction of knowing that they had approached them in a spirit of cordiality. They had had difficulties to encounter, but they had met with considerable success and encouragement. A list of photographers of the United Kingdom, numbering about 3000, had been compiled, who he hoped would join the Association. One great cause of complaint by photographers was that some firms who did a great deal of enlarging for the trade gave them no better terms than to those outside the profession, who were not dependent upon their business for a living. This was a most unfair action, as it practically took a large part of the business out of the profession which had been accustomed to have it. Some firms, however, had seen the injustice of this, and had undertaken to protect the profession in the future by allowing them a substantial discount. He looked to the members of this Association to support those firms who acted justly to them. He would go further, and say that one way of bringing it home to themselves was to bear in mind that they were not studying their best interests in supporting other houses who declined to act fairly with the legitimate photographer.

The report of the Council, after acknowledging the indebtedness of the Association to Messrs. C. P. Richards and Crosby for their efforts, stated that the subject of enlarging for the trade had received attention. In reference to the law of copyright, it was intended to prepare data on the subject, and the profession would be invited to forward suggestions on the subject. The following firms had complied with the wishes of the Association as to allowing trade prices to traders only:—Messrs. Elliott & Son, Marion & Co., the Autotype Company, the Eastman Company, Edwards & Co., Fry Manufacturing Company, Brooke Brookes, Slater & Co., the Birmingham Photographic Company, and others.

The adoption of the report was moved by Mr. THOMAS FALL and seconded by Mr. G. V. YATES (Sheffield), and it was agreed that, together with a list of members, it should be printed for circulation.

Mr. JAMES MARTIN hoped the Association would not depart from the principles of free trade, and complained of the action of those who advertised enlargements in the journals at very low prices, which were read by the whole photographic world as well as amateurs.

Mr. FALL said it was the firms in a large way of business that the Association had to fight against, and so far they had been very successful. Catalogues and advertisements had, in some instances, been withdrawn, and new lists sent out. There was no attempt at protection or coercion on their part, they were simply acting on the defensive, and he was ashamed of the apathy of the London photographer.

Mr. MARTIN hoped that when the Association got more fully established, the labours of the provincial photographers would be gratefully recognised by all those who benefited from them. He himself had adopted one list of prices, as suggested by Mr. Fall.

Mr. JOHN CROSBY was somewhat disappointed at the thin attendance, and regretted the London photographers had not accepted the invitation to be present in the spirit with which it was given. This question was one of bread and butter for them. The price lists of large firms not only got in the hands of amateurs, but also in those of the general public, who got their enlargements at the same price as photographers. He advised members of the Association to boycott the firms that did not use them fairly.

Mr. MARTIN spoke of the "dreadful facility of the pressure frame" as a factor in the cutting of prices, large firms sometimes finding competitors in their former errand boys. There was a large Association of amateurs the members of which expected printing done on trade terms not only for themselves, but also for their sisters, cousins, and aunts. They also got their enlargements done at twenty-five per cent. less than trade prices. These orders should go through the professional photographers. Amateurs became fully informed of trade terms from the advertisements which appear in the journals.

Mr. FALL thought they had less to complain of the amateurs than of the general public, assisted by the large firms. After quoting instances where such firms had allowed the same terms to the public as well as to the photographers, he said he wished it to be understood by photographers that great benefits had accrued from the work of the Association, which had received communications from several firms expressive of their determination to behave better in the future.

Mr. T. K. BIDDLE thought the Association should deal with the free crayon dodge, which was a direct fraud on the public.

Mr. FALL said the subject had been introduced at one of the Council meetings, and it was felt that the police-courts would be better able to deal with it. It was working its own cure, as they had now nearly gone all over the kingdom, and photographers were not suffering.

A guarantee fund of 76*l.* was announced. The following were elected to form the Council for the ensuing year:—*President:* Mr. T. Fall, London.—*Vice-Presidents:* Messrs. Chevalier Lafosse, Manchester; Robert Slingsby, Lincoln; H. J. Whitlock, Birmingham.—*Council:* Messrs. W. Barry, Hull; T. Birtles, Warrington; — Bromage, Bridgnorth; Warwick Brookes, Manchester; W. J. Byrne, Richmond; J. Chancellor, Dublin; W. Cobb, Tottenham; T. Storey Davis, Halifax; W. E. Debenham, London; J. E. Eddison, Barnsley; J. Elliott, Elliott & Fry, London; J. Fergus, Largs; T. Forrest, Pontypool; — Guy, Cork; William Gill, Colchester; R. P. Gregson, Blackburn; Abel Lewis, Clifton; Donald MacIver, Leeds; James Martin, New Southgate; H. S. Mendelssohn, London; W. H. Midwinter, Bristol; John Moffatt, Edinburgh; C. Pettinghall, Liverpool; Frank M. Sutcliffe, Whitby; Carl Vandyke, London; H. Van der Weyde, London; F. M. Whaley, Doncaster; G. V. Yates, Sheffield.—*Hon. Treasurer:* Mr. John Crosby, Rotherham.—*Hon. Secretary:* Mr. C. P. Richards, Barrow.—*Secretary:* Mr. D. J. O'Neill, 47, Charlotte-road, Birmingham.

Mr. FALL proposed a vote of thanks to the retiring President, Mr. Whitlock, for his services to the Association. This was seconded by Mr. CROSBY, who testified to the deep interest which Mr. Whitlock took in the Association. Mr. WHITLOCK briefly replied, and the proceedings terminated.

Our Editorial Table.

MESSRS. MARION'S catalogue of photographic material and apparatus contains illustrated particulars and prices of all the requirements of amateur photographers. The preface gives some good advice to amateurs in reference to the selection of apparatus.

MESSRS. PERCY LUND & Co. have compiled an index to current photographic literature, which, if not exactly "supplying a long-felt want," is handy for reference. Its usefulness, however, is impaired by several omissions, a defect which, we gather, will be remedied in future editions.

BURTON'S MODERN PHOTOGRAPHY (Piper & Carter, 5, Furnival-street, E.C.) has reached its tenth edition. Several alterations, that were received from the author too late for adoption in the previous edition, are included in this. The work, as we have before said, is an excellent handbook for a beginner.

THE Thornton-Pickard Company's new CATALOGUE contains particulars of several improvements which have recently been made in their time and instantaneous shutter, as also a new shutter for snap-shot and hand-camera work. This is said to be the only blind shutter which automatically covers the lens and protects the sensitive plate whilst setting for the next exposure.

THE second number of the PHOTOGRAPHIC REVIEW OF REVIEWS is admirable. The literary contents are selected with evident care and judgment. The Editor writes somewhat severely of the "namby-pambyism" prevalent among photographic societies, the truth of which we regret to have to admit, and Dr. Hall Edwards's discourses on the recent "Art Craze." The illustrations to the *Review* are capital, both in subjects and as specimens of photo-mechanical reproduction.

THE aim of the ILFORD MANUAL OF PHOTOGRAPHY (The Britannia Works Company, Ilford), by Professor C. H. Bothamley, is to serve as a trustworthy guide in the actual practice of the art. This aim is fully achieved, as the treatise is a clear exposition of the principles and practice of modern photography by a most able writer. The book includes a number of reprints of Mr. Howson's articles, various reference tables, and a list of dealers and dark rooms, and in printing and get-up is decidedly attractive.

PATENTS COMPLETED.

IMPROVEMENTS IN AND RELATING TO AUTOMATIC PHOTOGRAPHING MACHINES.

No. 699. JOHN MACINTOSH MACKAY MUNRO, 136, Bothwell-street, Glasgow, and JAMES MACFARLANE, 9, Holland-place, Glasgow.—*January* 16, 1892.

THIS invention, which relates to improvements in automatic photographing machines, has for its object to make the action of such machines more simple and durable, and requiring less attention than hitherto.

The action of this improved machine is as follows:—The person to be photographed stands in front of the machine, and uncovers the lens, or the coin slot, or both, by pulling or pushing aside a handle or lever. This movement is transmitted, by cord, chain, metal rod, or other device, so as to wind up the weight or spring which actuates the mechanism to an extent sufficient for delivering at least one card. This arrangement of the winding appliance so as to uncover the lens or coin slot, or both, ensures its being properly attended to, and that without the operator being aware that he is winding up the machine.

An alternative method of securing this semi-automatic winding up of the machine would be to place the head-rest, with or without a reflector, on a lever or metal rod, so that the act of folding or pulling it down or up into position would wind up the machine. To ensure the proper use of this head-rest-winding arrangement, it would be fitted with an attachment, so that it could not be pulled down till the coin was put in the slot, and so that the finished card could not be delivered till it was replaced.

With the first method of semi-automatic winding the dropping in of the coin would preferably allow the machine to start; with the second, this object would be preferably accomplished by a small press button or pull.

Another alternative method would be to enclose the space between the reflector and the pillar, leaving a part next the machine in the form of a little gate, and so connecting the gate with the clockwork that the opening and shutting of the gate by the people entering or leaving during the use of the machine would, by the movement of the gate, accomplish the winding of the machine. To provide against interference with the mechanism by undue or ill-timed movement of the gate it is necessary to provide arrangements so that the action of the gate, and, indeed, of all the self-winding devices on the clockwork, will cease when it is fully wound up, and also so that the clock can be wound while the clockwork is going. We prefer to do this last by using a spring instead of a weight as the driving force, the winding arrangement being attached to the one end of the spring, and the clockwork to the other, so that the action of the winding does not interfere with the movement.

Another alternative method is to arrange the machine so that the finished card cannot be withdrawn from the delivery chamber until the cover is drawn aside, and the performing of this act winds the clockwork.

Another alternative method is to provide a strong pointer with a handle, with the directions that if not already there it be placed opposite the mark "Clear" or "Dull," according as the day is clear or dull. Besides uncovering the lens and increasing or diminishing the light aperture, this movement would wind the clockwork. The handle would of itself go back to zero when the photographic exposure was complete.

When the first mentioned method of uncovering the lens is adopted the details usually preferred are as follows:—A penny must be dropped in the slot before the lens cover is unlocked. The lens cover is then pulled aside. This may allow the mechanism to start, the cover remaining down until exposure is complete and then replacing itself, or to secure the greatest steadiness of the person being photographed the penny dropped into the slot may, after the lens cover is withdrawn, re appear at a lower slot, too small however to allow it to come out altogether. The actual starting of the clockwork would then be effected by pushing this same penny inwards.

We find it sometimes advantageous, in carrying out the above, to use the principle of the wheel and axle, or other mechanical method, to make the pull easier by increasing its travel relatively to the distance through which the weight is lifted. A pawl and ratchet is also sometimes provided to let the weight be wound without moving the clockwork, as in winding of clocks, and a second pawl and ratchet may be provided, so that levers or handles may be replaced without any effect on the clockwork or weight. A stop is provided, so that, when the clockwork is fully wound up, any further movement or working of the levers is spent upon a spring-tight or other slipping arrangement, which, while firm enough to lift and sustain the weight without slipping, is yet loose enough to slip before any injury can be done to the apparatus by improper use of the levers or pulls, or the same purpose may be effected by arranging so that the winding appliance is thrown out of gear when the weight is wound up, and not restored until it is run down or partly run down.

As one of the chief objects of making the above winding arrangements, instead of using ordinary clockwork periodically wound in the manner adopted in most machines hitherto in use, is to lengthen the time which the machine can work without attention, some provision is necessary for renewing the developing and other solutions. We accomplish this by having supply reservoirs of fresh solution, with overflow reservoirs for exhausted solution.

A tube from the fresh supply is led over or into the vessel containing the working solution, an air-valve or stop-cock being opened and closed at intervals by the clockwork-driven mechanism, so as to permit any desired quantity of fresh solution to pour into the working vessel. The old solution may either overflow at the surface into a suitably arranged receptacle, or the lower part of the working solution may communicate by a tube with a small reservoir arranged to keep at same level as the working solution and to overflow when it rises beyond the desired level. The receptacle into which it overflows must in either case be of such size and shape that it may receive the overflow safely, although the vessel containing the working solution be rotating or otherwise moving, or alternatively a syphon may be employed to remove the used solution, in which case it must be provided with a stop-cock or valve periodically opened by the clockwork mechanism.

If the machine is thus to be left for a considerable period without attention, there must be a large reserve of photographic sensitised plates, ferrotypes, or paper, as the case may be, with a delivery box. If very many plates are used, the weight of these plates pressing upon the slide interferes with its smooth working. To obviate this, the slide box may be made as an inclined plane or spiral, or otherwise, for all or part of its length, so that cards may be partially supported by the sides of the box, or, alternatively, a number of the plates may be supported by a special support, which may be gradually lowered, but will be finally drawn aside by action of the clockwork.

Or, instead of using a slide-box delivery, the cards may be so arranged as to alternately overlap each other to, say, about a third of their length or breadth, and be upheld by two pins or rods, placed one a little nearer each end than the overlapping part. When one of the pins is withdrawn or folded down, the card on its side drops down into position opposite lens, being guided thereto by the shape of the passage leading from below box to this position. The next card is sustained by the other pin, which remains underneath it, and, as this card overlaps the one above it, no other card can fall. So soon as the first card is delivered, the rod which first moved is replaced. When another card is wanted, the second rod similarly moves and releases a card. In this way, the rods being all moved alternately by the clockwork, the cards are delivered one by one. Another method would be to construct a circular box, within which the card would be laid spirally, so that each one would overlap for a part of its length and breadth the preceding card; the process being continued till the required number is placed in the box. Projections from the inner side of the outer surface of the box would be fixed so as to assist in placing the cards properly and to prevent them moving out of position till wanted. This box would rotate on its axis over a plate or series of balls or rollers, which would be so placed as to sustain all the cards except one. When this one card fell into delivery channel the card immediately above it in the spiral would be sustained by the overlapping of the cards next to it, and so on till the whole were exhausted.

Another alternative method would be to place the cards (ferrotype metal usually) standing upright on and across an inclined plane leading to the proper position before lens. The cards would be placed close, one against another, except that a very thin plate, preferably of metal, would be between each. This supporting plate would be so attached to an arm that each plate would support a card. These arms, with their plates, are lifted one by one by the clockwork, beginning at the end next lens. As each card is thus freed from its supporting plate it falls down on the inclined plane, sensitised side uppermost, and so passes to position opposite lens.

IMPROVEMENTS IN MAGAZINE OR DETECTIVE CAMERAS.

No. 2516. ARTHUR JOHN BUNCHER, Whittall-street, Birmingham.—*January* 16, 1892.

THIS invention relates to improvements in magazine or detective cameras, or, in other words, that class of cameras in which a number of sensitive plates are stored, and successively used or exposed, as occasion requires.

By my invention the plates are automatically taken from a pile or battery of plates, and from thence transferred to a position, face forward, at the back of the camera, and in a focussed position opposite the lens, which is situated at the front of the camera, while at the same time a previously exposed plate or plates is, or are, stored at the back of the camera, and at the back of the last transferred plate.

My invention consists, in the first part, in the construction of the camera box. In the second part, in means for feeding the sensitive plates from a pile to the camera. In the third part, in the construction or formation of the compartment for the reception of the pile of plates. In the fourth part, in a telescopic plate-feeder, and, in the fifth part, in guide or race means for elongating the plate-feeder, in order that the same can follow up the plates during their transit into a focussed position. In the sixth part, in means for tilting the plate prior to the engagement of its carrying frame with the hooked end of the feeder. In the seventh part, in the plate-carrying frames.

The camera box is an erect six-sided figure, open at top and rear, and with the front enclosed, and fitted with an inside disposed, or other lens. The front upper part of the box is made after the manner of a well or receptacle, with an open bottom, but with the opposite sides of the said well, in the direction from front to rear of the box, provided with plate rests, in the form of flanges or shelf strips, running about two-thirds from front to rear of the well as aforesaid, and then inclining or curving themselves downwards to vertical stop rests, against which the edges of the carrying frames of the plates rest when in a position for exposure.

Running parallel with the said plate and stop rests is a curved race or guide for the purpose as hereinafter described.

The underside of the back end of the partition of the well is open to a height of the depth of the plates from the tops of the horizontal rests, whilst directed at the upper back part of the camera, and in the same plane as the top of the horizontal plate rests as aforesaid, which supports the pile, is a platform or floor, with the fore part next to the partition of the back end of the well, open, wherethrough the plate to be transferred to its assigned position across the camera downwardly passes.

The rear termination of the platform or flooring is provided with an upwardly directed curve or inclined part for tilting or transferring the plates from a horizontal to an inclined position, so that the hooked end of the feeder can engage with a hooked fore part of the plate-carrying frame, so that, as the plates, which are placed face upwards, are transported or conveyed from the pile, they are slid rearwards, and followed up by the feeder, and their front ends then made to impinge against the aforesaid curve or incline, which lies within the path of their traverse, hence the first tilting of the plates by the said curve and the complete turning of them to a vertical position upon the front edge of the platform by the feeder.

The extreme back of the camera, which is the store for the exposed plates, has a spirally coiled spring, which admits of the spirals taking the same plane as each other when compressed, although a flat spring may be used in lieu thereof if necessary.

The feeder consists of an arm jointed at its lower end to the front of the camera, and adapted to turn inwardly, and with the axial ends extending through the opposite sides, for the operation of the same, by turns or short arms connected to them.

The upper end of this arm, or quadrant working arm, is provided with a supplementary piece, which works telescopically, and slides within its upper part, so as to admit of the feeder lengthening itself, consequent upon the angle made by it, and in order to follow up the plates in their traverse rearwards.

The two opposite edges of the supplementary sliding part have outstanding pins or studs, which work within races or upon guides of the figure or contour of the plate or stop rests, but with the lower parts of the said races or guides left open for the clearance of the feeder in the passing of the same back to its normal position, which is in front of the carrier, and beyond the front edges of the plate frames piled within the well or store.

The plate frame has an open front and a closed back, with the metal at two opposite sides turned over, and with the front middle part slightly extended and made hookwise, whilst the middle part of the closed back has a lip for holding the said plates in the frames.

Operation.

Assuming a pile of plates, face upwards, to be within the well, and a loose bearing plate to be placed at the back of the camera, and to be pressed home by the spring, the turning fully back of the feeder slightly lifts the plates, and brings the top edge of the supplementary part of the feeder on a level with, and at the back of the front edge of the bottom plate of the pile, and with the outwardly directed studs or pins taking within the race in the sides or walls of the camera. The turning inwards of the feeder causes its upper edge, as aforesaid, to impress itself against the bottom plate, which is then traversed rearward by the impingement, passing under the partition walls at the back of the well upon the top of the platform or table, and above the opening, and with the front part impinging against the incline, which said front part, on traversing up the same, tilts the plate upon the front edge of the platform, as a fulcrum, and causes the supplementary end of the said feeder to hook or link itself with the plate frame, which is then raised thereby into a vertical position at the back of the partition rear wall of the well, when the feeder and plate descend, with the latter coming at the front of, and pressing back the previously exposed plate or plates, if any; if not, then the false back, as aforesaid.

The front of the last-exposed plate bears against the vertical stop rests, and with the feeder lying flat upon the bottom of the camera box.

At the same time that the plate is transferred from the well to its position for exposing, the pins or studs of the supplementary part travel within the races, channels, or guides, and so distend or contract the telescopic part so that the end of the same shall constantly bear upon, or follow, up the plates. To transfer another plate from the pile, turn back the feeder, when the pins or studs return clear of the races, and the said feeder takes an erect position at the back of the then bottom plate of the pile, and with its pins or studs opposite to the entrance to the race.

Improvements in, or Appertaining to, Camera Obscuras, and in Devices whereby the same are Rendered Operative by the Insertion of a Coin of Predetermined Value.

No. 1482. Edward William Banner, 16, Hargreave-street, Southport, Lancashire.—*January* 23, 1892.

This invention relates to camera obscuras and to devices whereby the same are rendered operative by the insertion of a coin of predetermined value.

The camera obscura may be of any suitable form or construction, but, by preference, I propose to provide a rotatable dark chamber, of conical or other suitable form, having a flat screen or surface at the bottom, and a mirror at the top, which is adapted to reflect the image of the object on to the screen aforesaid. The object glass and eyepiece are placed in suitable positions, and when the apparatus is not in use, both are concealed by shields or protectors, which exclude light, moisture, and dust from the mirror and lenses.

The dark chamber is adapted to rotate on a suitable vertical spindle, having a pulley and weighted cord, or its equivalent, which causes the dark chamber, after being rotated, to resume its normal position, namely, the position in which the eye and the object glasses are concealed. In proximity to the spindle, I provide a pivoted lever, having at one end a suitable tray for receiving a coin of given value, and at the other a locking bar or block, adapted to resist considerable strain and pressure, and formed to engage a tooth on the spindle and lock it firmly in one position.

The mode of action is as follows:—

On dropping a coin of predetermined value through the slot of the machine, it falls on to the tray aforesaid, and its weight overbalances the pivoted lever, raising the locking block or bar, and freeing it from engagement with the tooth on the spindle. A stop prevents the said block from rising more than a given height. The spindle being now released, the operator can rotate the dark chamber by a handle, thus moving it away from the shields or protectors which conceal the object and eyepieces. By this movement the stop aforesaid is also moved, the coin tray is further depressed, the coin drops off into a money receptacle, and, the weight of the coin being thus removed, the locking block resumes its normal position. The beams of light enter through the object glass, the image of the objects in the field is reflected by the mirror on to the screen, and the picture is revealed to the operator on his looking through the eyepiece. The object glass and eyepieces may be provided with lenses or with plain glass, whichever is desired, and the latter has a hood, which prevents light passing into the chamber when a person is looking into the camera.

By slowly rotating the dark chamber, a complete panorama of views of the surrounding neighbourhood is portrayed on the screen, and, at the same time, the weighted cord, or its equivalent, is wound up.

When the operator has finished, he releases the handle, the dark chamber rotates back by the weighted cord, and the spindle is locked in the manner already described, the locking tooth being chamfered at one side to facilitate its passing the locking bar. The object glass and eyepiece are thus again concealed by the coverings aforesaid, until released by a coin in the manner already set forth.

The screen may, if desired, be capable of adjustment so as to bring it into proper focus. Suitable stops are provided to limit the rotation of the dark chamber.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
February 22.....	Dundee Amateur	Asso. Studio, Nethergate, Dundee

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

February 11,—Mr. J. Barker in the chair.

Mr. J. Howson presented a copy of the *Ilford Manual of Photography* for the library.

Messrs. A. I. Taylor, J. Pearce, and A. Ullman were elected members of the Association.

Mr. J. Howson said, with regard to the subject of permanency of gelatine prints on Alpha paper, introduced at the previous meeting, the pictures in The British Journal Photographic Almanac for 1887 were produced by Mr. Urie, of Glasgow. At that time that gentleman's automatic machine was not perfected, and there was some difficulty in getting the prints in time. Mr. Harman visited Glasgow, and found they were being produced "acid toned and without any gold." Mr. Harman pointed out that permanency was improbable under this treatment, and it was arranged that this should be remedied. This would account for some of the prints in the Almanac fading while others remained quite perfect. Speaking of the permanency of gelatine over albumen prints, he said the former were to be preferred, and quoted several authorities on the subject. He passed round some prints on Alpha paper which were exposed November 1886, and developed November 1891, claiming that they were as good as if exposed recently. He concluded that Mr. Debenham had not been reported correctly when he was said to have classed gelatine and albumen together.

Mr. Debenham said the report was correct; the chances were often in favour of a developed print rather than one printed out. He questioned whether any "authorities" of importance had said that albuminate of silver was the sole cause of the fading of prints on albumenised paper. Only a few weeks since Mr. Bolas had explained the causes of fading. He considered photography had suffered by persons stating that silver prints were permanent. There could be no guarantee as to the permanency of silver prints.

Mr. F. A. Bridge said he had recently been shown some stereoscopic prints on albumenised paper made thirty years ago. Some of them were equal in every way to prints produced recently.

Mr. E. Milner said he had a few days ago examined a collection of prints made in 1856, which were apparently unchanged.

The Chairman had some old prints which had never been toned at all, and these were perfectly good.

Mr. Howson then introduced the subject of the evening, viz., *Isochromatic Plates*. He mentioned Colonel Waterhouse as having used eosine with collodion, and considered that hearty thanks were due to Tailfer for his method, and to Messrs. B. J. Edwards & Co. for bringing it before the photographic world. He questioned whether landscape work was improved by the introduction of a yellow screen, as sometimes the colour became over-corrected.

by its use. He explained that at one time he was sceptical as to the advantages of isochromatic plates, but a little experiment which he made, and which he would introduce to the meeting, convinced him of their utility.

Mr. Howson then exposed half an isochromatic plate and half an ordinary plate behind a negative, in front of which were four strips of coloured glass (blue, yellow, green, and red). On development the result was in favour of the isochromatic half, only one section being visible on the ordinary plate.

Mr. EVERETT asked if isochromatic plates would give correct results without a yellow screen?

Mr. AUSTIN EDWARDS said it had never been claimed that isochromatic plates gave absolutely correct gradation.

Mr. EVERETT quoted from an advertisement wherein it was stated that "These colour-sensitive plates yield isochromatic effects *without a coloured screen*."

Mr. COLLS said a yellow screen necessitated about six times the ordinary exposure, and for studio work this was impossible. Without a screen he had never found any difference between an isochromatic and an ordinary plate, say, on such subjects as a blue sash, or a white frock, or a face covered with freckles.

Mr. DEBENHAM objected to the statement that eosine without ammonia was useless. It had been proved to the contrary by reliable workers. Besides, Obernetter's plates gave good results, and these were not prepared with ammonia. He questioned whether we were so much indebted to Tailfer as to Colonel Waterhouse.

Camera Club.—February 11.—Commander C. E. Gladstone, R.N., gave a lecture on *Architecture in Normandy and Brittany*. Sir George R. Prescott, Bart., occupied the chair. Previous to the lecture, Mr. Maskill handed round a torsioscope, lent by Messrs. Adams & Co., an instrument devised to show eccentric distortions of portraits, and the Hon. Secretary exhibited some novelties in shutters sent by the Thornton-Pickard Manufacturing Company. Commander Gladstone's lecture consisted of an exposition of the leading beauties and features of church and domestic architecture in Normandy and Brittany. Each point was illustrated by lantern slides of very high quality. The history and growth of art in architecture in those countries was described, and a comparison between French and English styles and details instituted. On February 22, Messrs. Humphery and Davison will give a demonstration of printing in platinotype and development in the course of elementary lectures at the Club. On February 25, a series of lantern slides will be shown by Mr. J. B. B. Wellington, chiefly pictures in Norway.

The Lantern Society.—February 8.—Mr. G. R. Baker read a paper on *Dissolving Views, and How to Exhibit Them*. Mr. Baker commenced by speaking of the early history of dissolving views, and showed, by means of the lantern, how registration of the slides was effected in those early days. He then explained the methods of preparing slides for effects, and showed the most recent arrangement for obtaining accurate registration of slides, at the same time pointing out the difficulties that have to be got over to obtain a satisfactory result. He then showed a number of slides showing how effects could be obtained by means of two or three lanterns, the use and management of the tilter, the rolling curtain, and various methods of dissolving and changing slides. Photographs of Sir David Salomons' beautiful lantern were then shown on the screen, and Mr. Baker pointed out the various adjustments that had been made to get as near perfection as possible. At the conclusion of the paper, a number of high-class hand-painted slides and effects were shown with the triple lantern.

Hackney Photographic Society.—February 11, Mr. J. Hubert (Vice-President) in the chair.—Mr. Hepworth delivered a lecture on *Illustrated Journalism*. Introducing the audience to a "rag shop," he proceeded to trace the manufacture of paper from that source to the point where its ragged appearance is changed to the elaborate clothing of spotless material, suitable to receive the articles of such papers as the *Graphic*, *Daily Telegraph*, &c. The lecturer illustrated the methods of ancient and modern newspaper illustrations in a striking manner. The photographs taken personally by Mr. Hepworth included one where the stoppage of the machinery for that purpose occasioned the loss of three pounds, though it lasted only a few minutes. The different stages of preparing the drawings, often from the scantiest materials possible, such as a few lines, with marginal notes to indicate crowds, trees, &c., were developed truthfully into the beautiful pictures produced in first-class journals. The subject was specially interesting to photographers, inasmuch as it taught them to what extent photography had replaced the crude methods of the past. Mr. A. L. Henderson will give a lecture on *The Riviera* on Thursday, the 25th.

West London Photographic Society.—February 12, Mr. Hilton in the chair.—Mr. L. C. Bennett was appointed Secretary, and Mr. W. S. Rogers Assistant Secretary in place of Mr. Harry Selby and Mr. Leslie Selby, resigned. After the formal business Mr. J. A. Hopkins read a paper on *The Plate, the Negative, and some Remarks on Dodging*. He mentioned the different characteristics of commercial plates, and described the process of emulsion-making, dwelling on the advantage of using iodide. Although he did not wish to minimise the importance of what was called a good technical negative, it was still more important to photograph with a motive, and develop something to the particular effect desired, which would give a more artistic result, as a rule, than merely aiming at technical excellence. In his hands pyro, as an all-round developer, worked best, although he should not wish those who succeeded with any other developer to discontinue the use of that by which they got good results. His impression was that plain pyro was best for negatives, giving, upon the whole, the best prints, and showing truer gradation than when a preservative was used. He touched upon the various "dodges" that could be resorted to to improve the negative, mentioning, amongst other things, tissue paper, which was pasted on to the back, and then worked on with pencils of varying hardness, which could be easily done without injuring the negative in any way. Mr. WHITING spoke of the advisability of sticking to one kind of plate for all-round work, as it was easier to master the development and get the effect desired than by constantly changing. He rather disagreed with Mr. Hodges as to the advisability of using dry pyro. He thought the yellow colour of a negative so developed was rather misleading in printing; he could not see that the gradations obtained were any truer than when a preservative was used, in which case the density could be judged of better. One way of working on a negative which he thought good was to varnish the negative with white, hard varnish, thinned down considerably. When dry, rub the surface rather hard with the finger, and it would presently rub up white and rough, and then would be produced one of the best surfaces to work on that could be obtained. Afterwards dab the finger, covered with chamois leather, into a little powdered plumbago, and rub lightly on any parts of the negative that required intensification, or the surface could be worked on with a pencil. Mr. COLLS said he sometimes rolled up a little red ochre in some putty, and dabbed it on the back of the negative. It gave a good opaque matt surface, and could be strengthened easily by a little harder dabbing on the required parts. Mr. MILLER objected to such extensive dodging as was often resorted to. He thought it was much better, instead of using pencil, brush, crayon, and so on so extensively on a negative, to use them on drawing paper, and he referred to the practice of working on prints which he had seen at exhibitions in very uncomplimentary terms. Messrs. H. Selby, Winter, Stein, and others also took part in the discussion. The future meetings of the Society will be held at the Chiswick School of Arts, Bedford Park, Chiswick.

Putney Photographic Society.—February 10, Dr. W. J. Sheppard in the chair.—The Rev. L. Macdona read a short paper on *Lenses*, the third of the series. Speaking briefly on the principles of light, he described the action and construction of the various lenses in the market, single and double, narrow-angle, wide-angle, &c., pointing out the particular uses of each variety. For general all round use he recommended a rapid rectilinear or rapid symmetrical, whose focal length was equal to one and a half times the length of the plate to be used. Some rough metal castings, finished castings, rough crown and flint glasses, polished glasses, and the complete finished lens, all kinds supplied by Messrs. Taylor, Taylor, and Hobson, were passed round, and served to illustrate the lecturer's meaning. Samples of the Eastman extra rapid bromide paper were distributed at the close of the evening. On February 27, *Exposure*, Dr. J. F. Farrar.

Richmond Camera Club.—February 12, the President in the chair.—Mr. St. John Hunt showed and explained Roberts's hand camera, Mr. Arthur Hunter a home-made apparatus for viewing lantern slides, and Mr. Ramsey some negatives and positives enlarged with cresco-fylma, and some by a process of his own discovery. Mr. Hodgkin then read a paper on *Photographing Pottery*, explaining that he had taken up that branch of work at the request of his father, Mr. J. E. Hodgkin, who was bringing out a book on the inscriptions on early English pottery, with illustrations, chiefly from his own valuable collection. For this purpose Mr. Hodgkin photographed some fifty or sixty pieces, most of them by lamplight, and his paper clearly explained his *modus operandi*. Edwards's isochromatic plates were used, the reflection and distribution of light varied to suit each subject, and exposures of varying duration, up to four hours, were given. A paraffin lamp, with ground-glass globe, was the principal source of light, a candle being placed as near as possible to the object to bring out the highest light at the proper point. The required negative having been obtained, a silver print was sent to a firm in Vienna for reproduction by photo-mechanical process. Specimens of negatives and prints were handed round, and showed how successfully Mr. Hodgkin had carried out his difficult task. One of the process blocks was also shown, and a proof copy of the book, which is doubtless destined to become one of the standard works on ceramics.

Birkenhead Photographic Association.—February 11, the President (Mr. G. A. Carruthers) in the chair.—Some prize slides had been announced as the attraction of the evening, but they failed to turn up, owing to some error in the date of booking. An excellent programme for the entertainment of the members was, however, provided by the President and the Secretary, the former exhibiting a set of slides in description of a trip in the north of Ireland, whilst the latter read an illustrated paper on "Emral," Flintshire, the ruined family mansion of the Pulestons. The limelight used during the evening was produced from oxygen alone, by means of A. W. Scott's warm air saturator, which was manipulated by Mr. W. F. Archer, of Liverpool.

Bristol and West of England Photographic Association.—February 12, the President in the chair.—The Secretary distributed some samples sent by the Eastman Company of their rapid bromide paper. They also sent a neat and well got up *souvenir* of the Washington eleventh annual Convention. After some discussion on the local photographic survey, Mr. HARVEY BARTON gave a lecture explaining his new apparatus for flashlight portraiture. The prints shown were soft and very nice. An adjournment was made to Mr. Barton's studio, specially fitted up for flashlight work, and some half dozen plates exposed on different people present were afterwards developed, and turned out perfect negatives. Mr. Barton uses eight flashlamps (connected together by piping with bellows) placed ten or twelve feet above the ground, muslin curtains being placed between the sitter and the lights. Half a grain of magnesium powder is used each time in each lamp, which contains a sufficient quantity for a number of discharges. On February 19, the Secretary will give a short paper on *Photographic Prints in Colours*.

Derby Photographic Society.—February 9.—A quantity of sample packets of Eastman's bromide paper were distributed. The Thornton-Pickard Company also sent specimens of their new shutters, which were much appreciated. It was proposed to hold a *conversazione* and public exhibition of members' work early in November, thus giving the members an opportunity of preparing pictures for this purpose during the summer.

Preston Camera Club.—February 11.—Mr. Macintosh gave a practical demonstration of lantern-slide making by contact. This Club intends to hold an exhibition of members' work, with lantern evenings, on March 1, 2, 3.

Correspondence.

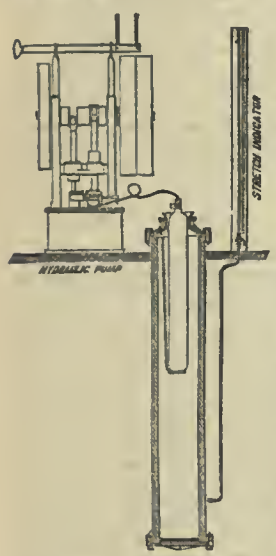
TESTING OXYGEN CYLINDERS.

To the EDITOR.

SIR,—My attention has lately been drawn to several letters in your JOURNAL touching upon the strength of oxygen cylinders, and it has occurred to me that some of your readers may be interested to learn how they are treated before being placed upon the market.

It has generally been considered sufficient to test cylinders by simply pressing them with water to the desired pressure, but this system is very faulty, inasmuch as, although it shows a cylinder's capability of withstanding the required pressure on that occasion, it does not indicate if it has become damaged thereby. To overcome this difficulty, several trials were made in 1890 with an apparatus which was designed to indicate the stretch of cylinders, with which very marked results were obtained, and this plan of testing has now been adopted at these works.



The illustration shows the testing apparatus, which explains itself. Each cylinder, on reaching the works, receives a number, by which it becomes known; it is filled with water in the usual manner, and is placed vertically in an iron envelope, as shown, and is supported by three chains. The envelope also is filled with water to the exclusion of air. A perfect joint is made round the shoulder of the cylinder by means of a flexible rubber ring, which can be at will instantaneously inflated by means of water drawn from any convenient source; in this manner all communication between the envelope and the atmosphere is closed, with the exception of an outlet through a small-bore glass tube, which serves as an indicator of displacement or stretch. The cylinder is then coupled up to the hydraulic pump, and the test is made as follows:—The height of the water in the gauge glass is first marked. The pressure is then put slowly into the cylinder by means of the pump, and stretch in every case is shown from the moment the first indication of pressure is seen on the pressure-gauge; the water in the gauge glass rises with every stroke of the pump, until the maximum pressure is reached, on release of which it falls, with good cylinders, to its original position, showing that the elastic limit of the metal has not been passed, and the cylinder in no way damaged. The cylinder is then stamped with the test-mark if proved sound, the pressure of the test, and the date, and the test is recorded in a book, with the name of the maker and the signature of the person who saw the test carried out.

All cylinders destined for a working pressure of 1800 pounds are in this manner tested, in these works, to 4000 pounds per square inch; and, for fear of over-straining them, special care is taken that the makers do not previously test them to more than this pressure, which is considered to be a safe and sufficient test for cylinders of the section and quality of steel now employed.

I feel that I have already trespassed on your space, and will not go into the many experiments which have been made, but will simply point out that a forty-foot oxygen cylinder, when tested to 4000 pounds, has sufficient elasticity to displace, an an average, a column of water 22 inches high × ¼ inch diameter, and to return again to its original state; this cylinder would measure 5½ inches diameter × 31 inches long × $\frac{7}{32}$ inch thick. It will, therefore, be readily seen that this system of testing gives an insight into the behaviour of the cylinder whilst under pressure, with sufficiently broad results to be easily applied and appreciated in the ordinary workshop by any intelligent man.—I am, yours, &c.,

HENRY BRIER.

The Scotch and Irish Oxygen Company, Limited, Glasgow,
February 15, 1892.

PERSONAL.

To the EDITOR.

SIR,—Mr. Coles, at the meeting of the London and Provincial Society, as reported in your last, plainly suggests that I misquoted Professor Burton, with a view to make good my statement. This is a question of fact, and can easily be verified, if true, and I invite Mr. Coles to do so, or to make apology for thus traducing me. I press this point because I am known to be more than moderate in any claims I make, and I do not want to lose this reputation undeservedly.—I am, yours, &c.,

JOHN HOWSON.

The Britannia Works Company, Ilford, London, E.

RATIO OF GRADATION.

To the EDITOR.

SIR,—Does not all this discussion arise out of a mere confusion of terms? Nine hundred and ninety-nine photographers out of one thousand use the word density (as applied to negatives) in the sense of opacity, that being the only property of the deposit which is of importance in the printing frame. But Messrs. Hurter & Driffield (and Mr. Phillips in your last issue) use the word density as signifying the amount of silver deposited on a given unit of space, which is an entirely different matter.

Therefore, while Messrs. Hurter & Driffield may be, and probably are, quite correct in saying that the ratio of gradation in density cannot be altered by development, the practical photographer is equally correct in asserting that it is an every-day experience with him to alter the ratio of gradation in *his* density (or opacity) by a modification of development.

Messrs. Hurter & Driffield's original article in the *Journal of Chemical Industry* was a difficult nut to crack, but they put the matter in a clearer light in the April number of your defunct contemporary, the *Photographic Art Journal*.—I am, yours, &c.,

ALFRED WATKINS.

Hereford, February 12.

To the EDITOR.

SIR,—The thanks of photographers are due to Messrs. Hurter & Driffield for publishing the results of their further experiments detailed in your issue of February 12. Unfortunately, the conditions of that experiment do not seem to have been made to approximate as nearly as could be wished to the conditions present in the case of the experiment of Captain Abney, with which a comparison is sought to be made.

The problem is this:—

1. A plate is exposed upon a subject for such a time that a given density (rightly, and quite usefully, described as printing density) is developable in the parts of the negative which represent the least bright parts of such subject.

2. The range of gradation in the subject is such that the application of a normal developer to the plate so exposed results in full printing density being developed in those parts which have been exposed to the brightest lights before the parts which have been exposed to the least bright light show sufficient developed density to be of printing value.

These being the postulates, is it possible, by an alteration of the relative constituents of the developer, to develop up to printing density the parts which have been exposed upon the least bright portions of the subject by the time that, or before, the parts exposed to the brightest portions have attained full printing density?

Captain Abney says that it is possible, and that he has done it.

A consideration of the result of Messrs. Hurter & Driffield's experiment, tabulated in the column headed B, would seem to show that the second of the conditions postulated was not complied with, for the application of the normal developer resulted in developing a very considerable relative density in the parts of the plate which had been exposed to the least light at the time when the parts exposed to the brightest light had attained what may be described as full density.

In other words, the range of gradation, though apparently great (being 1 : 64), "is insufficient to decide the question;" and this objection was foreseen by Messrs. Hurter & Driffield, for they state, apparently as a reason for not taking a more extended range of gradation, "that the total range of gradation which the plates we used were capable of rendering truly lies in between exposures of 40 and 220 candle-metre seconds."

It may, however, be remarked that photographers have to do the best they can with the total available potentiality of rendering gradation of which the plate they are using is capable, and that if in practice a subject has such an extended ratio of gradation that at both ends the plate is incapable of rendering it with mathematical accuracy, nevertheless, they must make the nearest approach possible thereto; and, if science is to aid them in their work, science must investigate, by means of experiment, the factors which come into play when the plate is forced beyond its capacity, and made to render, as well as it can, such an extended range of gradation.

Once more, therefore, in searching for an explanation which will reconcile the apparently discrepant results given by exposures in the field and exposures in the laboratory to a sensitometer (using that word as it was used by me before, and as I conceive it rightly may be used, not as meaning exclusively Warnerke's or Spurge's sensitometer, but generically to describe any apparatus for facilitating the exposure of photographic plates to lights of various intensities), we are led to suspect that the explanation will be found by a consideration of the effects of over-exposure, perhaps carried so far as to result in partial reversal, and that, under the abnormal conditions thus introduced, the action of the developer may itself be

abnormal, in the sense that alterations of its constituent parts may effect changes in the resulting negative different both in kind and in degree from those which would have been effected had there been no over-exposure.

A very simple example of general occurrence will exemplify this. A plate may be so over-exposed that the application of a normal developer, however long applied, will result in a flat negative—*i.e.*, one in which there is no great density in the highest lights, and a clouding of the shadows. If, however, a suitable developer be applied instead of the normal developer, density may be developed in the highest lights, and the shadows remain clear. Surely the ratio of gradation in such a case is altered, and, if so, is not unalterable by the constituent parts of a developer, which is the proposition Messrs. Hurter & Driffield adhere to, though it appears now contrary to what I believe was the general impression of readers of their original paper, that they are not prepared to assert that the *ratio of gradation* is the same, or practically the same, whatever developing agent be used. Perhaps they will forgive me for pointing out that the passage cited from their original paper, "There is a theoretical possibility that a plate may be rapid to one developer and slow to another, so as to require different exposures according to the developer used," does not imply that there may be any variation in the *ratio of gradation* if different developers be used, but merely that, with a developer X, a plate would be slow, showing only the effects of exposures equivalent, let us say, to 40 and 20 candle-metre seconds; whereas, with a developer Y, the same plate might show the effect of the feebler light of 10 candle-metre seconds as well as the 40 and 20.—I am, yours, &c.,

Davos-Platz, Switzerland, February 14, 1892. M. J. MICHAEL.

ALUMINIUM CAMERA FITTINGS.

To the EDITOR.

SIR,—As some of your correspondents were good enough to put me on the right track for procuring aluminium, it may interest them, as well as other readers of your JOURNAL, to learn the result of my inquiries.

One letter was returned, noted "Gone away." In a second I was told, "We shall be glad to quote for whatever quantity you require." In the third case a list was enclosed, from which, for the information of your readers, I extract the following prices per pound, ninety-eight to ninety-nine per cent. pure:—

Sheet: B. W. G., 0 to 14,	8*s.* 2*d.*;	15 to 24,	9*s.* 3*d.*;	25 to 30,	10*s.* 3*d.*
Wire:	,, 10*s.* 6*d.*;	,,	10*s.* 9*d.*;	,,	11*s.* 6*d.*
Rod: ½–¾ inch,	10*s.*;	⅛–½ inch,	9*s.* 8*d.*;	¾–1 inch,	9*s.* 2*d.*

As I was passing through Birmingham I thought it well to pursue my inquiries. I was directed to a shop in Warstone-lane, which I could not find; but, seeing a likely shop in the immediate neighbourhood, I went there to inquire. My questions were answered with some evasion and reluctance, and, upon stating that my idea of the price was from 8*s.* 6*d.* to 10*s.* a pound, I was laughed to scorn, and told that aluminium in ingots was 3*s.* 6*d.* an ounce (say, three shillings and sixpence an ounce)! Eventually, I bought some ingots, warranted ninety-nine per cent., at 4*s.* a pound (four shillings a pound).

When I was last in London I procured sheet aluminium, cast rods, and castings for milled heads from stock patterns from the Phœnix Engineering Company, 40, Prince's-street, Stamford-street, S.E. These, including a triangular tripod head, with castings for nut and screw, cost me 21*s.* The quantity was considerably more than I shall require for one half-plate camera; but, as I have had no experience in working the metal, I thought it best to allow for wastage.

Being in Birmingham again about a fortnight ago, I extended my inquiries. At a metal and tube shop I was asked, for aluminium ingots, 8*s.* 6*d.* an ounce! This, I was told, was absolutely pure; but, upon pressure, it came down to ninety-nine per cent. A camera manufacturer was good enough to supply me with a small quantity of sheet at 5*s.* a pound; at another shop I was offered ingots at 2*s.* 9*d.* a pound. It is quite beyond my power to explain these discrepancies.—I am, yours, &c.,

February 16, 1892. QUADRILOBINUS.

A COMEDY OF ERRORS.

To the EDITOR.

SIR,—In your last issue reference is made to me in a way that is misleading. The facts of the matter are these: I have on several occasions urged that *gelatino-chloride* prints, being minus that unstable compound albumenate of silver, or any equivalent thereof, may be considered as permanent.

To this end I have quoted the opinions of Captain Abney, Professor Burton, Mr. Chapman Jones, Mr. C. H. Bothamley, and Mr. E. J. Wall, as scientific experts; of Mr. John Barker and Mr. John Stuart as practical workers—on whose theory and practice I have founded my claim.

Mr. Coles first attacked me, saying that certain *bromide* prints had faded. I replied that bromide was not in question, and, if it were, we must first know whether the prints had had proper manipulation.

Now some *Alpha* prints are brought out, some of which have faded.

As we have since ascertained that many of these prints were "acid-toned," being passed out of the acid-clearing bath direct into hypo, owing to the culpable carelessness (or worse) of the photographer who made them for us, there need be no surprise that many of them have faded; but this has not any bearing on the question whether gelatine prints in general are unstable or otherwise, neither has it the very remotest reference to my original claim for *gelatino-chloride*.

Mr. Debenham is reported, in one of your contemporaries, to state "that he did not, of course, include as wanting in permanency those images which, printed originally in silver, had been converted by substitution into gold or platinum."

Qualifying this by excepting albumen prints, owing to the possible formation of albumenate of silver, as above mentioned, this confirms to the full my opinion, and I shall therefore continue to consider Ilford printing-out paper as permanent until some higher authorities than those I have quoted, or some well-proved facts, show I am wrong.—I am, yours, &c., JOHN HOWSON.

The Britannia Works Company, Ilford, London, E.,
February 18, 1892.

A PHOTOGRAPHIC INSTITUTE.

To the EDITOR.

SIR,—In your article last week on *A Photographic Institute*, I observe that you would exclude the teaching of art at present, on the ground of some uncertainty in the minds of photographers as to what is "the meaning and application of Art in relation to photography." The very statement that you make, that just now every one has his own pet idea, might have suggested that many must of necessity be wrong; and, if so, the greater the reason for Art being included in a projected curriculum.

The importance of this subject to the general public, to say nothing of photographers, coupled with the fact that personally I have taken very great interest in this subject, and, inferentially from the pet ideas, wasted much breath and ink on it, may possibly excuse my intruding an idea of my own on your notice.—I am, yours, &c., PHILIP H. NEWMAN.

February 13, 1892.

WEST LONDON PHOTOGRAPHIC SOCIETY.

To the EDITOR.

SIR,—The Council of the West London Photographic Society desire to call the attention of photographers residing in the west of London, particularly Chiswick and Gunnersbury, to the fact that the head-quarters of the Society have been moved to the Chiswick School of Arts and Crafts in Bath-road, Bedford Park, one minute's walk from Turnham Green Station, and they hope to have a considerable accession of members from that district. They have arranged to hold frequent meetings of a social character in addition to the ordinary meetings, when papers are read, &c.; and, considering that the Society is now so well known, they think that many ladies and gentlemen would like to join it now that it has moved to Chiswick. Any information as to the Society will be gladly furnished.—I am, yours, &c., LIONEL C. BENNETT, *Hon. Sec.*

30, *Blandford-road, Bedford Park, Chiswick.*

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Will exchange an excellent Lerebour whole-plate portrait lens for a good quarter-plate set.—Address, P., 3, Hinckley-road, Leicester.

Wanted, Dallmeyer's patent "3 D" lens in exchange for really good backgrounds, interiors, exteriors, and graduated.—Address, DRAYCOTT, 11, Gold-street, Northampton.

Wanted, posing chair, smoking-chair pattern; will exchange English lever silver watch.—Send photograph to J. C. O'LOAN, 26, Fernside-terrace, the Common, Woolwich, S.E.

Wanted, 15 × 12 rapid rectilinear or symmetrical lens, by Dallmeyer or Ross, in exchange for pneumatic safety bicycle; difference adjusted.—Address, J. H. GERMAN, photographer, Paignton, Devon.

I will exchange background (interior), 8 × 7, for a graduated ditto; also half-plate single landscape lens and Tylar's print washer for tapestry curtain or exterior background.—Address, FRED. C. D. HUBD, Shepton Mallet.

Wanted, good lantern or half-plate camera in exchange for eight volumes of the JOURNAL, three volumes bound, all complete and clean as new, with plates, ready for binding, up to December '91.—Address, SIDEY, 35, Richmond-road, Dalston, E.

Will exchange whole-plate portrait lens, by Derogy, Paris; Kershaw's instantaneous shutter; Perkin, Son, & Haymont's instantaneous shutter. Wanted, studio chair or table, balustrade or rock, in exchange.—Address, Porter's Studio, Chippenham.

Will exchange very fine 12 × 10 lens, by Horne & Thornthwaite, rack and pinion, two interior canvas backgrounds, large size Booth's mitre machine, nearly new, Optimus rocking print washer for 9 × 7 prints; wanted, 1 × 1 lens for views, ship's bulwark accessory, or rock accessory.—Address, COUSE, Durham-street, Hartlepool.

I will exchange a Burr's extra quick-acting portrait lens, No. 2*a*, two and three-quarter inches diameter, four and a half inches focus, cost six guineas, in new condition, for a good half-plate folding camera and stand, with three double slides; also a well-made mahogany Kinnear camera, screw adjustment, one single and one double slide, for a good half-plate rapid rectilinear lens.—Address, GRIMSHAW, 16 Dale-street, Haslingden, near Manchester.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," *2, York-street, Covent Garden, London.*

W. M. BUTLER and F. S.—Thanks; in our next.

JAS. CONNOLLY.—A piece of washed chamois leather.

W. R. THOMSON.—We have no information beyond that which appears in the report referred to.

ARTHUR BUTLER (10, King's-square, E.C.).—Mr. H. J. Channon's address is, Woodlands, Lewisham, S.E.

A. B. M.—Unless the copyright is registered, no proceedings can be taken for its infringement, or, at least, they would be of no avail.

A. HENDRY.—The letter *re* the Kimberley Exhibition appears in the JOURNAL for September 18, 1891. It gives all the information required.

A. W. N.—No great skill is required in enamelling prints. By following the instructions referred to, a little experience will beget proficiency.

E. DENVERS.—An article on another page will give about all the information you require. If that does not make the matter clear, write again.

REV. WALTER MARSHALL.—"Stereoscopic Photography" forms the subject of our article in the ALMANAC for 1887. This will probably suit your purpose.

E. J. S.—1. None that we are aware of. 2. Weak gaslight would suffice. 3. No. 4. Practically about the same sensitiveness. 5. Yes, if no moisture be present on the stone.

QUADRAGESIMUS asks: "Nickel-plated screws, &c. Will any one kindly tell me where to procure nickel-plated hood screws (brass or iron), and aluminium strap and butt hinges?"

PRINTER.—Dextrine, though a very convenient mountant, should never be used for photographs, as it is invariably acid, and therefore likely to act deleteriously on the picture.

A. WOOD & SON (6, St. Bernard's-row, Edinburgh).—We have not kept the address of "Lux," who wrote us regarding a prism. Perhaps, if he sees this, he will communicate with you direct.

M. GARDNER.—The process by which opal pictures are produced of the colour of red chalk, or the Bartolozzi tone, is the "carbon" process, the tissue being made with a suitable red pigment.

BERKS.—The work is in German, and there is no English edition of it. As it was published some years ago, and consequently is not up to date, there is no probability of one being issued now.

P. CORNELL.—In making chloride of gold for toning silver prints, the small quantity of alloy, when using current gold coins, may be entirely disregarded, as its presence will practically do no harm.

C. RAYNER.—If the carbon tissue in its insensitive state has become mouldy through being kept in a damp place, it is, we fear, of little use. The only way to determine the point for certain is to sensitise a piece and try it.

S. PRATT wishes to make a solution of indiarubber in chloroform, and asks if methylated chloroform will answer the purpose, or must the more costly kind be employed?—The methylated will answer quite as well as the other.

CARL NORMAN & Co.—The address of the Frederick Crane Company, the makers of the varnish mentioned at p. 762 of the ALMANAC, is Birmingham, but Mr. J. R. Gotz, of 19, Buckingham-street, Strand, is their London agent.

R. H. P.—The prints themselves are not in the least altered. The paper has, however, undergone a change for the worse. You must bear in mind that, in this regard, photography is almost entirely at the mercy of the paper makers.

BURNISH.—There are so many good burnishers now in the market that it is very much a matter of taste as to which is considered the best. It may, however, be taken somewhat as a guide that price, in a great measure, governs efficiency and durability.

C. JONES.—1. Perhaps some of the readers of the JOURNAL may be able to supply you with "a good formula for removing the silver stains from a negative." We are not aware of one. 2. There is no reason why the solutions should not be kept mixed.

R. G.—Gelatino-bromide prints are obtained by development of a latent image exposed to artificial light. Gelatino-chloride is a "printing-out" process. Whether one process is "better" than another depends entirely upon your own requirements, and these you do not specify.

BURNETT.—1. As near as convenient. 2. By the brilliancy of the disc. 3. Yes; with sufficient exposure. 4. Not necessarily. 5. Quite. 6. A round silver burner answers every purpose. 7. An excellent plan; we should, however, recommend artificial light on account of its invariability.

AVONDALE.—Are you sure that the oxalate of potash you have used is all right? We should advise you to procure a fresh sample from another source, and supposing the paper has not been allowed to absorb moisture, if that does not get over the trouble, send samples of the failures to the makers of the paper.

F. PEEL says: "To-day I developed a negative, and to my astonishment the subject came out reversed—that is, what was on the right-hand side came out as if it had been on the left. Can you in any way account for the phenomenon?"—Yes; certainly. The plate was put into the dark slide glass side towards the lens.

R. ST. JOHN.—To give *full* working details on any of the photo-mechanical processes in the space allotted to this column is quite out of the question. To give full practical information on any one of them could not be done in an entire JOURNAL. Plenty of sound information on the different methods is to be found diffused through our back volumes.

NOVICE.—The preservative bath should be discarded before it begins to deposit crystals. We do not know the strength it is made, or how compounded; possibly it may become super-saturated by evaporation. There is no necessity to trest the solution with kaolin. It is better, as it is so inexpensive, to throw it away after it has been used a few times.

A. ROGET.—From the sketch, the proposed studio will answer every purpose. It is not at all necessary to have glass on both sides. If it be glazed, as suggested, it will answer every requirement. One end may be used in the morning and the other in the afternoon. The opaque side of the room should be papered, or painted, of some light neutral tint, such as a French grey or an unobtrusive pale green.

J. O. B. says: "Can you explain to me the following circumstance? When I mixed the toning bath for the Ilford printing-out paper for the first time or so, instead of getting a clear fluid, I got one which threw down a white flocculent precipitate, and refused to tone. A friend of mine got the same. I was told it was the excess of sulphocyanide of ammonia, but I don't think it is, because next time I carefully weighed it."—If the bath were prepared according to the instructions issued with the paper, and it refused to tone, there was some fault with the materials used. Possibly impure water or unclean vessels were employed.

O. A. K. says: 'I want to make lantern slides of a number of hymns, and I find the greatest difficulty in getting a good black deposit with a clear glass ground. My negatives are made on Mawson's photo-mechanical plates, and are good strong ones; a genuine black and white, quite clear of fog in the letters."—Our correspondent adds that he has tried several brands of lantern plates and different developers. He also complains of the keeping qualities of lantern plates. There ought to be no difficulty in the matter, as such slides are easy to make. Possibly the negatives, though clear, are not dense enough, though of a black and white character.

W. WRAY.—Your correspondent cannot have had much acquaintance with lenses, else would he have known that, in comparing two, the first thing to be done is to bring them both to the same angular aperture by the insertion of a suitable diaphragm in the one which has the largest relative aperture. Both the interior and exterior photographs enclosed speak strongly for the admirable covering power and definition of the lens, although it was used with full aperture, which ought not to have been the case with a lens possessing so large a diameter relative to its focus.

THE PHOTOGRAPHIC CLUB.—February 27, Monthly Lantern Meeting. March 2, *Halation.*

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—February 23 (Technical Meeting), *Retative Merits of Different Processes for the Production of Lantern Slides.*

WE are informed that Messrs. R. Field & Co. are now sealing up the rolls of sensitive paper for refilling the Watkins' exposure meter, so that the paper will keep perfectly good for any length of time in all climates.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—February 25, Members' Open Night. March 3, *A New Enlarging Lantern without Condensers*, Mr. S. H. Fry. March 10, *Collodio-bromide Emulsion*, Mr. A. Mackie.

WEST LONDON PHOTOGRAPHIC SOCIETY.—1892: February 26, Lantern Evening. March 4, Technical Social Meeting. March 11, Mr. John Howson, *New Ilford Plate.* March 18, Technical Social Evening. March 25, Mr. C. Whiting, *Useful Hints on Picture-making.* April 1, Technical Social Meeting. April 8, Lantern Evening. April 22, Mr. R. Whiting, *The Artistic Improvement of Negatives.* April 29, Technical Social Meeting. May 6, Technical Social Meeting. May 13, Annual Dinner.

BRIGHTON PHOTOGRAPHIC SOCIETY.—The next meeting of the Society will be held on Tuesday, February 23, 1892. Immediately upon the termination of the meeting, a special general meeting will be held. The following is the agenda:—To consider the deficiency, and to adopt resolutions thereon. Motion by Mr. Cansh: "That the members be asked to contribute towards a fund to pay off the deficiency." Motion by Mr. Foxall: "That this Society, known as the 'Brighton Photographic Society,' be dissolved, such dissolution to take effect immediately upon the settlement of the liabilities of the Society."

ON Monday afternoon the boys of the Liverpool Institute, Mount-street, were called together in the Lecture Hall for the purpose of presenting the honorary testimonial on parchment of the Royal Humane Society to James H. G. Wood, aged fourteen years, son of Mr. James Wood, the inventor of the "washer" called after his name, "for having, on September 1, 1891, gone to the rescue of Thomas Shields, who was in imminent danger of drowning at Milford Haven, and whose life he gallantly saved." The Head Master, Mr. Alfred Hughes, M.A., gave particulars of the rescue, and praised the boy for his pluck.

JOURNAL OF PHOTOGRAPHY.

No. 1660. Vol. XXXIX.—FEBRUARY 26, 1892.

BICHROMATED GELATINE AND ITS EXPANSIVE PROPERTIES.

In a leading article in our penultimate issue, the analogy in the behaviour of a film of gelatino-bromide of silver to one of bichromated gelatine was treated of. As the interest taken in photo-mechanical processes is increasing, we shall here point out some of the peculiarities of bichromated gelatine as regards its expansive properties. In the first place different samples of gelatines vary considerably in the proportion of water they will absorb. Some take up several times the quantity that others will, and the larger the proportion of water absorbed the greater is the expansion of the gelatine.

When gelatine is soaked in cold water, it not only expands in thickness but distends in all directions. It may be mentioned here that the temperature of the water in which the gelatine is soaked is a factor in the case. The higher it is the greater is the absorption, and *vice versâ*. By way of experiment we placed a thin flake of gelatine, of German manufacture, containing twenty-two square inches, and weighing the same number of grains, in water at 60° Fahr. After soaking for twelve hours it measured just thirty square inches, and had increased in thickness from about that of thin foreign note paper to that of a stout visiting card, while its weight had increased to 235 grains. It will be noticed that the expansion was proportionately greater in the thickness than it was laterally. The lateral expansion of gelatine is familiar to most persons, even those who have not given special attention to the subject, in the frilling of dry plates. Advantage has been taken of this, coupled with Plener's method of stripping the film with hydrofluoric acid, to obtain a patent for enlarging negatives. The plate is simply placed in a mixture which contains fluoric acid until the film is detached, and allowed to expand, when it is floated on to aother glass.

When a photographic image in high relief is required, a gelatine should be chosen that is the most absorbent of water. For, as a rule, gelatines retain their original characteristics after treatment with the bichromates, that is to say, a gelatine which is highly absorbent before treatment is proportionately so afterwards. We say as a rule, because the presence of foreign matters, such as alumina or other insolubilising substances, greatly modify the conditions; yet with a tolerably pure article it holds good. Now, if a film of gelatine, containing a small proportion of bichromate of potash, be spread rather thickly on a glass plate, and dried in the dark, then exposed to light under a negative, until a visible image is seen, and afterwards soaked in cold water, an image more or less in relief will be obtained. Those portions protected by the negative will be in the highest relief, and those exposed in the lowest. Instead of spreading fluid gelatine on glass, a thin sheet of it, such as that used by lithographers, may be sensitised and printed. When the print is allowed to soak in cold water, it will expand in all directions, consequently the image will become larger laterally, while, all things being equal, the relief will be less than in the former case.

While the image is in the swelled state it may be moulded from with plaster of Paris, or other material that does not require heat for its application. As the raised portions are still soluble in warm water, it of course follows that any substance applied hot would bring about their solution. If the swelled film is allowed to dry, the relief nearly or quite disappears; but it can be restored again by resoaking, though, perhaps, not quite to the original extent.

Supposing that the film is formed of a tolerably hard gelatine and, after sensitising it, dried at the normal temperature, the surface of the image, after soaking, will be smooth, hence a cast taken from it will be smooth also. It is quite possible, however, to so modify the gelatine with different materials, and, at the same time, varying the temperature at which it is dried, to obtain a rough or grained surface instead of a smooth one. For example, if a bichromated film on glass be dried at a temperature of 60° Fahr., and then exposed under a negative, it will have a perfectly smooth surface when swelled in water; whereas, if it be dried at a higher one, say, from 110° Fahr. to 130° Fahr., it will be found to be rough and grained. A close examination will show that the grain is a discriminating one, inasmuch as it is coarser in the deepest shadows, finer in the middle tints, while in the high lights, where the light had least action and consequently the gelatine is most swelled, there is practically no granularity at all. Upon this property are based collotype and analogous processes of printing.

It is usually explained in text-books that the collotype process is dependent upon the property of bichromated gelatine, after exposure to light, becoming more or less non-absorbent of water, while the protected parts retain their original state, so that when the ink is applied it "takes" on the film in proportion to the light's action. That is so; but it is not all. The reticulation or puckering up of the surface is an important point in the case as it becomes an ink-holding grain, which is strongest where most ink is required; finer in the more delicate portions, and almost, if not quite, non-existent in the highest lights.

By selecting a suitable gelatine, as well as further modifying it in the preparation of the plates, the collotypist is enabled to obtain a plate possessing the requisite qualities for his purpose with quite a minimum of swelling up of the film, which is an undesirable quality in a collotype plate. Hence it will be seen that the expansion properties of gelatine are subject to considerable modification when necessary.

LOSS OF DENSITY IN FIXING.

In a letter which we published in the Journal of February 5, our esteemed correspondent, Mr. Albert Levy, attributes a property to the hypo fixing bath which we do not think it really possesses. After suggesting that the makers should tell us whether their plates do or do not "lose much" in the fixing

bath, he goes on to inform us that he obviates loss of intensity in the hypo by over-development. He believes that many so-called under-exposed pictures are simply not developed enough to suit the extra loss in hypo, and that a somewhat under-exposed negative will lose much more in the hypo than a fully exposed one.

Now, density depends upon two operations, namely, exposure and development, and their product is an image of metallic silver on a layer of unaltered salt. Hitherto we have always understood that the only thing which a developed plate could lose in the fixing bath was the unaltered part of the picture. Mr. Levy, however, appears to imply that the developed silver image itself suffers removal, more or less, and in that implication he virtually attributes to hypo the property of dissolving metallic silver, since the density of the image is entirely dependent upon the quantity of the latter which has been thrown down by the developer. Probably hypo, employed at its normal strength and for a normal time, has some slight solvent action on the developed image of a gelatine plate; but, if so, it is tolerably certain that such an action is so inappreciably small as to be practically unworthy of notice in regard to the "loss" of density thereby caused.

Assuming, however, that our correspondent would not be willing to support the foregoing deduction, which, let it be remarked, naturally issues from his own premisses, some other cause for the loss of density of which he complains must be sought, and here we point out that, if hypo does not, as we submit it does not, dissolve the reduced silver of the image, there can be no *actual* loss of density in the fixing bath. We can, nevertheless, fully understand that with many plates there is an apparent loss after fixing, and the reason for this we believe to be easily explained.

In the first place, the image on a richly coated plate might, upon development, appear to have greater density than was subsequently found to be the case, simply because the thick film would lend itself to the illusion, and in such an instance, where development was stopped too soon, we can perceive how the fallacious idea might arise in some minds that the fixing bath itself was responsible for the "loss," the real explanation being that the plate was under-developed. With a thin film, on the other hand, the obstructing power of the non-actinic light would be considerably less than the thicker one, and thus this very paucity of emulsion might actually conduce to the obtainment of density by inducing the operator to carry on development until he had secured sufficient opacity, part of which, in the case of the thickly coated film, would be already provided for him.

But, in addition to thickly coated films, yet another property of gelatine plates might conceivably lead one astray in the estimation of the density of the developed negative. This is the presence in so many of the commercial plates of the present time of a certain proportion of iodide of silver, which, by its colorific property, may impart to the film an appearance of thickness, and thus also mislead one in the matter of the amount of density obtained. Iodide of silver, again, is to a great extent inert under the action of the alkaline developer, so that here, too, we may discover one of the causes of the assumed loss of density in the fixing bath.

The foregoing may possibly throw some light on the true cause of the difficulties experienced by our correspondent. That the image itself, as he seems to infer, loses appreciably in the fixing bath, we are unable to admit. The loss caused by the hypo can only be that of the unreduced salts, and the apparent loss of density is consequently in the inverse proportion of the undeveloped parts of the film. Hence it probably follows that the so-called loss of density in the fixing bath arises wholly and solely from under-development or under-exposure, or both in combination.

The Chicago Exhibition.—In our correspondence columns we print a letter from Sir H. Trueman Wood which conveys to intending exhibitors at Chicago a great deal of desirable and, at the same time, useful information in reference to their exhibits. It will be seen that applications for space should be sent in not later than February 29, after which date they can only be received subject to space being available.

Star Discovery by Photography.—The new star which has been discovered in the constellation Auriga turns out to have been photographed at Harvard in December last. The Astronomer Royal points out that it thus appears the new star had been photographed on three separate occasions in the course of the photographic mapping out of the stars, and that thus, with the aid of funds provided as a memorial of Dr. H. Draper, a photographic record of this star has fortunately been obtained two months before its recognition as a new star.

The New Hon. Secretary of the Photographic Society.—At their last meeting the Council of the Photographic Society of Great Britain appointed Mr. H. Chapman Jones, F.I.C. F.C.S., to be Hon. Secretary in place of Captain A. M. Mantell, R.E., who has resigned. We are certain that this appointment will give every satisfaction, not only to the members of the Society but also to many others who are interested in its welfare, Mr. Chapman Jones's personal and scientific claims eminently qualifying him for the position. The vacancy on the Council thus created will, we believe, be filled by Mr. Francis Cobb.

Photographic Measures of Stars.—The Astronomer Royal recently communicated a paper to the Royal Astronomical Society on this subject. This operation of measurement is by no means so simple a matter as would at first glance appear. The first point to determine was the relation between the diameter of the image of a star on the plate and the time of exposure. A large number of measurements were made with this object, and an empirical formula, for variations with a particular star, was developed for use, and, with other calculations regarding different magnitudes, a formula was obtained which, making use of the before-mentioned constant connected magnitude, diameter of image, and time of exposure.

Action of Light on Mercury Compounds.—A paper containing many facts of possible value in photography was read at a recent meeting of the London Chemists' Association. The subject was the action of light on mixtures of salts of mercury with compounds containing iodine mercurous chloride (calomel), and iodoform, decomposed red spots being produced on the sides of the bottle containing the mixture exposed to the light. With mercuric chloride ("bichloride") no action took place. Either green iodide of mercury, or iodoform mixed with the mercurous salt, quickly produced scarlet spots. Oleate of mercury and iodoform became first green, and then scarlet. In some cases, further action of light created a kind of reversal, the scarlet disappearing, and the original colour being restored. In most cases iodine was given off.

Something for Nothing.—Mr. Arthur Debenham, of Ryde, sends us a card, which was recently being delivered from house to house in that town. He says it shows the state of trade obtaining in the Isle of Wight, and adds, "What remains now except to offer a glass of grog in the bargain?" The card runs as follows: "Something for nothing! Do not miss it. Messrs. Billinghurst & Dovey, photographers, 121, High-street, Ryde, Isle of Wight, beg to thank the inhabitants of Ryde and vicinity for their very liberal patronage during the past nine months, and herewith make a special offer of

photographs gratis. Messrs. Billinghurst & Dovey will photograph any adult person producing this ticket free of charge, and give them one cabinet-sized photograph. Available any day from February 15 to February 22, both inclusive, from ten o'clock a.m. till four o'clock p.m. each day. These will be good photographs, executed in first-rate style, and sent out in rotation of taking. Messrs. Billinghurst & Dovey reserve to themselves the right of refusing to photograph any one not properly dressed, also babies and young children. Something for nothing! Read this carefully." We have carried out this last injunction to the foot of the letter, and are at a loss to understand why, if Messrs. Billinghurst & Dovey have enjoyed, as they say they have, "very liberal patronage" during the last nine months, they should have to resort to such methods as] the above for increasing their business.

Argentometer Indications.—Dr. William Ramsay, F.R.S. has been making a series of investigations on the action of particles suspended in liquids, and, in the course of the discussion that followed the question was asked whether muddy water gave a higher density than the same free from suspended particles. Mr. Friswell said it was well known that when oil of vitriol contained lead sulphate in suspension it was not possible to ascertain its density exactly; and Professor Ramsay pointed out that, as particles possessing the specific motion in a liquid which had been shown to exist exercise pressure, the result of their presence would tend to force the hydrometer bulb upwards, and thus cause an apparent increase in the density of the solution. It is, therefore, quite likely that one of the causes of the untrustworthiness of the hydrometer form of argentometer may be traced to this cause. It is, however, very surprising in how few establishments any other form is employed. There really is no need for this ignoring of a valuable instrument or method. For about half-a-crown it is possible to purchase a graduated tube, in which any schoolboy could, in one minute, gauge the strength to a nicety of any silver bath. The sample under examination is poured in the tube till it reaches a zero mark, and then, by small quantities at once, a solution of chloride of sodium of definite strength is added, till no further precipitate takes place. The figure on the tube opposite the level of the liquid at once, and without calculation, gives the grains per ounce. But even this simple instrument is not actually necessary. A definite quantity of silver bath is placed in a bottle; a two-ounce measure is filled with the salt solution, and drachm by drachm added till precipitation ceases. The bath then contains, say, four grains per ounce—or any other quantity, according to the strength of the precipitator—for each drachm of the salt solution required. It is very probable that one cause of this most valuable method being neglected is the fact that its use was originally complicated by the recommendation to employ an "indicator," that is, a further chemical added to indicate, by a change of colour, the approach of complete decomposition. This is absolutely unnecessary. In adding the chloride solution it will be noticed that, so long as all the silver is not thrown down, the flocculent particles remain suspended through almost the whole mass, and the surrounding liquid is evidently quite bright and clear; but, the moment the last particle of chloride of sodium necessary is added, the whole mass of precipitate sinks to the bottom, and the supernatant is no longer clear, but quite milky-looking.

WHY PHOTOGRAPHS FADE.

I.

At several photographic meetings lately, the subject of the fading of silver prints has been raised, and many amateurs will be in a state of doubt who to believe. On the one hand they are told that, if they print in silver (whether bromide developed prints or by the various printing-out processes), their time and money are simply wasted so far as any permanency in the results is concerned. On the other hand, they see in the advertisement pages of the journals silver printing processes said to be permanent.

Now, which is right? When one sometimes sees silver prints done thirty-eight years ago, with the whites of the picture perfectly pure, and not the slightest trace of yellowing or fading in the lightest tints—in fact, the prints as perfect, apparently, as the day they were done—one cannot but help thinking that there cannot be much the matter with a silver printing process that gave such results, and this even when the mounts had been damaged by damp.

But who produced these photographs? Ah, that is the secret, to a great extent, of the whole matter! They were done by men thoroughly well up in photographic chemistry. They used the best paper they could procure; they salted, sensitised, and prepared their *few* prints with every care. The time taken up in preparing the sensitive paper made them careful in their work at every stage. Then they altered their salting and sensitising baths, so as to obtain the best results from each one of their few negatives. A negative in those days represented time, enthusiasm, and patience. There was no "pull the string, press the button, and we do the rest" about it.

Their method of work is the only one by which any process ought to be judged, and yet we are actually asked to judge of the permanence of the various processes of the present day by the illustrations bound up in some book, probably produced, piecework, by the thousand, by a group of workpeople who would know and care as much about the permanence of their work as they would if they were making linen buttons at so much a gross.

To condemn a process under such circumstances is about as fair as the way one often hears at our Society's meetings in which a certain make of plates, &c., is condemned by some young fellow who has bought a shilling instruction book and a few dozen of plates, and thinks he is competent to give a conclusive opinion about everything connected with photography. It speaks much for the permanence of the printing processes of the present day, after seeing some of these young fellows at work, that their prints stand—I was going to say for a week.

And this brings me to the subject that is really the reason of my writing this article. How few photographers' assistants (and, in many cases, even the principals themselves) know anything of the causes that conduce to the fading and deterioration of their prints, whether they are working in silver, platinum, or carbon? It must be remembered that there is not a single one of these processes but will give prints which will deteriorate in time if proper care is not taken in their production.

Indeed, it is a grave point to my mind whether some of the manufacturers are as particular in the selection of their paper, &c., and its preparation as they ought to be. To get the best results when the prints are produced seems often to be the only thing they can think about, because they advise the addition of substances to the developer, &c., that cannot but be injurious to the prints as regards permanence. I believe it is done, as a rule, through ignorance, or, perhaps, want of thought, but it gives, or rather will give in time, their goods a bad name.

How many a photographer in a country town has had to curse the manufacturer for the ruin of his reputation through the fading of his prints, every one of them backed with the name and address of the producer.

At the same time the manufacturer and his goods are often blamed for the fading of the prints, which is really due to carelessness, or, perhaps, more often, want of knowledge of the importance of small details in fixing and washing the prints on the part of the photographer.

Perhaps a few notes which I have made during my many experiments on the subject of the fading of photographic prints may be of use to some who are at present quite unable to account for the reason of the deterioration of their prints.

As there are many amateurs who prepare their own chloride of silver printing papers since Mr. L. Clarke brought out his platinum toning process, I therefore purpose to go to the very beginning, namely, the paper before and after it is sensitised and follow on during the succeeding processes to the production of the finished print, and at each stage try to show how causes may arise to account for the fading or, at least, deterioration of the prints in a few years.

HERBERT S. STARNES.

AMERICAN NOTES AND NEWS.

Our Coming Convention.—And here *place aux dames*. It is somewhat gratifying to know that our United Kingdom Convention is sufficiently recognised by our Transatlantic *confrères* as to influence at least some of them in selecting the time of their visit to Europe. From a letter received from Miss Catherine Weed Barnes, Associate Editor of the *American Amateur Photographer* and *Outing*, we learn that our accomplished sister is arranging the duration of her intended visit to this country so as to embrace her participating in the pleasures of the Convention to be held in Edinburgh in July. It is altogether unnecessary to say that she will receive a most cordial welcome, both on account of her own acquirements and as repre-

senting photographic literature and art of a country which permits adies to occupy, like cream on milk, a high position.

A Law-suit Terminated.—We understand that the suits between the Celluloid Company, of America, and the Eastman Company, of Rochester, have now been satisfactorily settled in the interests of both parties.

A Specimen Letter.—The Scovill & Adams Company recently received the following letter: "Please send me one of those woden thing that wholes the lense to the Camera on the Scholars outfit i broke mine someway I don't know how. Yours truly R. S. P.S. Enclose 5c. if it is to much let it go & if it is not enough write & i will send you the ballance." Even in these enlightened days we ourselves not unfrequently receive communications equal in opacity to this.

An Edition de Luxe.—We have once or twice said that the Americans know how to engrave, and how to get up a book in an attractive form. It is not for us here to speculate as to the causes which have operated to conduce to this, but so it is. Of the various handsome books which America has produced, we question whether any has been issued which surpasses the *édition de luxe* of the last *American Photographic Annual* (Scovill & Adams Company, New York). Special paper, special ink, and special binding, it forms, quite apart from the merits of its contents, a book that in its get-up has never been surpassed.

Exhibition at Boston.—The fifth annual exhibition of the Photographic Society of Philadelphia, the Society of Amateur Photographers of New York, and the Boston Camera Club, which is open to all photographers, American and foreign, will be held under the auspices of the Boston Camera Club, at the galleries of the Boston Art Club, May 2 to May 11, 1892, inclusive. Mr. J. Herbert Seaverns, of 5, East India-avenue, E.C., will act as the English forwarding agent for the exhibition, full particulars of which may be obtained from Mr. George M. Morgan, Chairman of the Committee of Arrangements, 50, Bromfield-street, Boston, Mass.

Destruction of Silver Prints.—Discussing Mr. T. Bolas recent theory as to the fading of bromide prints by sulphuretted hydrogen, caused by keeping the prints in a damp place, our contemporary, the *Photographic Times*, remarks: "This is not quite correct. The image is not destroyed; it exists as silver sulphide, and may be revived." Probably; but we can understand that, if the prints be mounted in a book, and the paper of that book be damp, the sulphate of calcium in the paper, together with the organic matter also therein contained, may so react upon the silver sulphide originally formed as to cause the latter to diffuse throughout the book. In that case the image would not easily be restored. We believe that, on the occasion referred to, Mr. Bolas alluded to some such hypothesis in the course of his remarks.

Should Amateurs Sell their Pictures?—The Newark Camera Club held an exhibition the other day, and the visitors were given the opportunity of buying copies of such pictures as took their fancy, the money so obtained being devoted to defraying the expenses of the exhibition. Some of the local professional photographers took exception to this procedure, asserting that such sales injured the profession—the vendors, of course, being amateurs. But suppose the amateur's pictures were better than the professional's? And, whether they were or not, would anybody argue in favour of the prohibition of amateurs selling their pictures if opportunity offered? To do so would, we fear, be productive of considerable ridicule. The only remedy is for the professional to "go one better" than his amateur rival in the quality of his work. At present it is too often the other way. *Hinc illæ lachrymæ!*

Philadelphia Society's New Rooms.—We read in the *Public Ledger* an account of the recent opening of the Philadelphia Society's new room in the presence of a large assemblage of invited guests. The apartments consist of a commodious meeting and exhibition room, admirably arranged and adapted for the purposes in view; a reading room and library, well supplied with comforts, and a stock of books and magazines pertaining to photography in English and other languages, and a fully equipped working department, including dark rooms, &c. All are suitably fitted up, and furnished with modern appliances. The copy of our contemporary which brought us this item of information was stamped "Rescued from the wreck of the s.s. *Eider*," the unfortunate North German liner which went ashore off the Isle of Wight the other week. The paper had evidently had a good soaking of sea water, but the print was unimpaired.

Negatives for Enlarging.—Dr. Elleralie Wallace, in an article, "Negatives for Enlarging" (*American Journal of Photography*), gives it as his opinion that, with snap-shot exposures by the hand camera, in the case of animals, sharp results can only be expected when a finder, the duplicate of the lens used for making the picture, is employed. The focussing of landscapes is a very easy matter; but for all work of this nature, that is, for subsequent enlarging, it is advisable to have a stand of some sort to keep the camera steady. As a developer for such negatives, he favours an admixture of eikonogen and hydroquinone. Eight ounces of distilled water are heated to boiling point, five drachms of sulphite of soda are then added. When dissolved, forty-five grains of eikonogen, and fifteen grains of hydroquinone are added. When cold, the mixture is made complete by the addition of ninety grains of carbonate of potash, and for use it is diluted with an equal volume of distilled water.

Photography and Billiards.—The Lynn Camera Club has added a billiard table to its attractions, and the editor of the *Photographic Times* endorses the club's action. So far, so good; but our contemporary goes on to say that "One of the reasons why the English camera clubs are so popular is that they unite with the photographic attractions of their club rooms social attractions as well. Some of the leading clubs are not only provided with billiard tables, libraries, and reading rooms, but have well-furnished gymnasiums," &c. This is the first time we have heard of gymnasiums in connexion with photographic clubs, and we only know of one of the latter which boasts of a billiard table. We also learn that "the consequence is that the English camera clubs take the place to a great extent of other clubs." Oh, come now, good *Times*, who told you so? Again we say, this is the first time we have heard it; but there, as Mrs. Gamp observed, "What I knows *I* knows, and what you knows *you* knows."

Beauty and Temperament.—Instituting, in *Wilson's Magazine*, a comparison between so-called beautiful women and children, Mr. G. C. Rockwood, in speaking of what is expected of the photographer, says that mature beauty is often temperamental and not physical. With the children, everything is different. They are natural, tractable, and the impossible is not expected of artist or photographer. An adult, in sitting to the artist, endeavours to assume the expression he or she desires to wear in the picture. Few artists can divert her mind from the fact that she is being recorded. A child knows nothing about expression, has no vanity or desire to look its best. No man can make a speciality of children; the children must make a speciality of him. It's a pure case of selection or Nature's ordination. The children must love him. They have intuitive perceptions, and cannot be deceived by smooth words and pretty gifts, any more than the animal. They know their affinities by a nicer, surer test, which they cannot express.

Composite Photography.—We entirely sympathise with that veteran artist, Mr. Abraham Bogardus, who, in the *St. Louis and Canadian Photographer*, asks: "What has become of Composite Photography? During the excitement attending its short-lived popularity, I wrote my opinion of it for a New York daily paper. I characterised it as the most ridiculous nonsense to which photography had ever been applied. How any man of ordinary intelligence, or one

who had ever been accused of having brains, could have been induced to advertise and recommend a thing so utterly devoid of common sense and truth, is more than I could ever understand. I think it is very dead. It certainly keeps out of sight, and I hope it is buried so deep that it will not be resurrected." In this latter respect Mr. Bogardus is wrong; the artistic nuisance is not out of sight, and it is not buried. In an illustrated American paper we saw a few days ago there were numerous vile composites, composed of the forehead and eyes of one public character, and the nose, mouth, and chin of another—offensively patched together. And one of the newest of the new school of periodicals, the *Idler*, seems to depend exclusively for such popularity as it may attain upon a few examples of composites.

A Model Camera Club.—The St. Louis Camera Club have just completed their new quarters in the club house at 911, N. Vandeventer-avenue, where they will gladly welcome visiting members of foreign clubs. The quarters are provided with a commodious dark room, furnishing ample room for eight persons to work at once. It is equipped with electric lights, shielded by ruby, orange, and ground glass, giving an abundance of safe light by which to carry on work. All necessary chemicals for development are kept on hand for the *free* use of members in the rooms. The reading room is supplied with the best journals. The rooms are all heated by steam, and are therefore always comfortable, even in extreme cold weather. The gallery is properly arranged with a suitable skylight, and has attached to it another very comfortable dark room, which may be used for changing plates or for developing. It contains a good 10 × 8 copying camera, with lens for enlarging and reducing; an 10 × 8 portrait camera, with stand, &c.; also the usual backgrounds, screens, head-rests, &c. The large hall in the club house seats about 600, and is admirably adapted for lantern exhibitions, as it is lighted by incandescent lights and comfortably seated. The club hopes that their English friends who may visit St. Louis will not forget to pay them a visit; and, in making ourselves the medium of their invitation, we take leave to congratulate our St. Louis friends on the possession of such an excellent club house.

URANIUM TONING OF BROMIDE PRINTS.

[A Communication to the North London Photographic Society.]

Since I first published the results of my experiments for obtaining warm tones on bromide papers a good deal of attention has been given to the subject, both at home and abroad. I should like, if I could, to give you what I might call the whole subject of bromide toning up to date; but this would be a large order, as there are now so many methods suggested. In my first communication on this subject to THE BRITISH JOURNAL OF PHOTOGRAPHY, I expressed a hope that what I had written might lead others more experienced than myself in photographic chemistry to take up the subject and perfect the process—to complete the ship, of which I had laid down the keel, or to build another. It is gratifying to me to find that the matter has been pursued by several able workers, that many suggestions have been made for the production of these warm tones, that some others are promised us in the near future, and that, generally, the question of toned bromides has "caught on," as THE BRITISH JOURNAL OF PHOTOGRAPHY put it the other day.

VARIOUS METHODS OF TONING.

Some of the methods that have been suggested had formed the subject of experiment with me, and had been discarded before I hit upon the uranium toning method. Others—some being for the production of the tone by development direct—I had not tried. One of these, published in one of the German papers, and copied into the *Year-book*, seems to rely on the same principle as the method of development I have suggested *preparatory* to toning, the difference being that the developer is still more dilute than what I recommended. But there is another difference which takes the process quite away from what I had done. The tone is obtained by a *second* development. The first being much of the ordinary character, a weak eikonogen developer, giving a yellowish brown tone, the finished image is reconverted into bromide of silver. This is then redeveloped in daylight in very weak eikonogen, something like one-thirtieth the strength of the original developer. The reappearing image presents itself first as a peachy pink, and proceeds through different stages of warm to dark brown.

The action, of course, is very slow; I think you might set it to work in the morning, go to business, and find it not overdone when you return in the evening. This is roughly the principle which is followed, but you will find full particulars in the *Year-book*.

Another method which is promised, but which has not been publicly shown, comes from America. I saw some prints by this process some months ago, not knowing then that they were not produced by uranium toning. It is now announced, however, that the uranium, or whatever be the colour-producing agent, will be contained in paper, or rather in the emulsion. This forms the subject of a patent, and no doubt it will prove a valuable one. The prints I saw were very fine in colour. Yet another method is promised us by my friend, Mr. Haddon. He is said to employ a salt of copper, but I have no information on the subject beyond what was stated in the brief notice in the BRITISH JOURNAL OF PHOTOGRAPHY.

The various methods that have been suggested seem to me to be hampered mostly with two drawbacks. First, as a rule it is difficult to estimate beforehand what tone it is possible to get, or to obtain the same tone at two different times from the same negative. The second is that all these methods are more or less tedious, and this would particularly apply where redevelopment was resorted to. The perfect simplicity of the acid uranium method of toning, the variety of tones obtainable by it, and the power of getting the same time after time, has always appeared to me its special charm. You may be going over your collection of bromide prints, and one may strike you as being too cold for the class of subject. In a few minutes, if your laboratory contain the necessary stuff, you can judge of its appearance in sepia or a warmer brown. If it pleased you better as it was, pop it into running water, and in a couple of hours you will have it as it was.

WORKING OF THE ORDINARY URANIUM TONING PROCESS.

As regards the working of the process, for the benefit of those who may not have heard or seen it described, I will run rapidly through it, but I really do not think that there will be much to add to what has been already published. The first thing, of course, is to get good negative. One made with lantern-slide work and enlarging in view will save you a lot of trouble. Dense negatives require long exposures which are difficult to estimate, and seldom, with that, give soft results, develop ye ever so skilfully. As to exposure, the effect you wish to produce will have to be taken into consideration, but, in any case, I recommend a liberal exposure. A print that develops very brilliant—one that has been a little under-timed—will not tone well to the sepia or warm brown. It will be apt to look hard. For red chalk tones, however, which I will allude to hereafter, a stronger print should be produced. But for the present, we are dealing with the sepia and warm browns. A full exposure should, therefore, in my opinion, be given. The developer, again, should be made up to suit exposure and effect desired. I have recommended a dilute hydroquinone developer—say, one part of the mixed solution with two parts or more of water added; or, to put it otherwise, one part each of what we are in the habit of hearing called Nos. 1 and 2, or A and B, and four or more parts of water added.

This will not give a good black and white print. With slow Ilford paper it will give, in some cases, a very fair sepia, but generally a dirty brown. This brown image is the most amenable to the after-toning. With rapid papers you do not get this colour. In using them, you must expose and develop so as to get a soft grey image with full gradation. I don't mean the flat grey image resulting from over-exposure. The difference between the slow Ilford and any of the rapid papers under development is remarkable. With the recommended full exposure and dilute developer the image on the slow paper first makes its appearance in a yellowish fawn tint, getting redder as development progresses, and passing on through brown to what appears to be black by canary light. After fixing, this apparent black turns out to be a brown. This is my experience most markedly with hydroquinone, and not so much with para-amidophenol. This yellow and brown appearance during development has made me conjecture that the slow paper might be a chlorobromide. I have used a sample of para-amidophenol, which was kindly given me by Mr. Sargent, for some trials, and found it very suitable if sufficiently diluted. The development was slow. For producing good black and white bromides, however, it is not necessary to use it so dilute, but, as the development is very rapid, only the correct exposure is any good. It gives beautifully clear results.

A DEVELOPED BROWN IMAGE NOT A NECESSITY.

The brown image got by development is by no means a necessity, as the BRITISH JOURNAL seems to make me insist. I have only *recommended* it, when working with hydroquinone developer, as being more suitable for receiving the after toning. What, however, *is* necessary is that a soft and harmonious image be produced. Since the introduction of the

phenol developer I have found it very useful for this purpose, and have used it in the form of rodinal almost constantly in place of hydroquinone. It gives a print of great delicacy of a soft grey tone, and may be diluted for that purpose to from 1 in 100, to even 1 in 400, according to the strength of the negative from which you are working, and the effect you wish. Of course, diluted so much as the last figures, rodinal would be useless for producing black and white prints. They would be much too flat, but such an image, you must remember, gives very often an excellent toned print, as the toning agent has a decided intensifying effect.

The prints are, of course, fixed in the usual way, and the after-washing must be very thorough, as the least trace of hypo produces a red stain the moment it comes in contact with the toning bath. "Tae mak' siccar," as we say in Scotland, before toning, I treat the print for five minutes in a bath of—

Peroxide of hydrogen (20 volumes)	1 part.
Water	40 ,,

and wash again for five or six minutes.

The toning bath may be conveniently made up of the following strength:—

Glacial acetic acid	10 minims.
Potassium ferricyanide.....	½ grain.
Uranium nitrate	½ grain.
Water	1 ounce.

This will not act too rapidly. It may, of course, be made stronger if desired, and I do so on occasions. The prints quickly change colour, the sepia stage being reached in a couple of minutes, and five or six minutes, as a rule, being sufficient to get the warmest brown you would care for. If carried on, the toning will continue till it reaches a heavy black red, and until recently this was the nearest I could get to the chalk-red or Bartolozzi print tint. Within the last few weeks, however, I have discovered a mode of getting much brighter red tones, and this I will describe presently. The toning action may, if you like, be carried on some shades beyond the colour it is intended to finish, and the final determination of the stopping point left till the next stage, the washing. But this over-toning, again, is by no means a necessity, although it has been suggested that I have insisted upon it, and that I thereby erected a barrier to its simple working. The print may be taken from the toning bath as soon as the desired colour is reached, for the necessary after washing is so slight that very little reduction will occur.

Washing, Drying, and Finishing.

The coloured image, or rather the coloured deposit on the image, however, is very soluble in water, so that any *too great* redness can be easily got rid of simply by continuing the washing a little longer. When the print leaves the toning bath, the high lights are of a lemon yellow colour. Five or six minutes in running water will be sufficient to remove this, and the print is then ready for drying and finishing. If it be, however, still warmer than is desired, the washing will be continued till the colour has reached almost what is wanted, some allowance being, of course, made for a little darkening in the drying.

This point being reached, it is important that the print be blotted off in clean blotting-paper or calico till it is surface dry, as, if the moisture be left in patches on the surface, there will be inequality of tone when the paper is dry. This forms a decided drawback to the use of uranium as a toning agent for lantern slides, as it would be sure to spoil a slide to blot it surface dry, unless there is some absorbent substance that could be used for the purpose that leaves no woolly stuff behind it. The use of spirits to expel the water will, no doubt, obviate this difficulty. The omission of the blotting off in the case of paper prints has been the cause of a good many failures which have been referred to me by correspondents. To produce a set of prints, all of the same depth of colour, blot off one at the required colour, and set it on a glass plate, or any other clean support, at the side of your washing tank, blotting off the others, one by one, as they reach the same tint.

I may just add a word here as to the mounting of prints. Some enlargements have been submitted to me in which the tone has been considerably reduced at places. This is caused by the prints having been wetted on the surface by the mountant, and allowed to dry in that state. After mounting I always run the print over with a sponge just damp, and in that way secure equal moisture on the surface and even drying.

Chalk Red or Bartolozzi Effects.

This, I think, brings me to the end of the ordinary toning process. It has taken a lot of telling, but in practice ten minutes will do the toning and washing for a print in warm brown. I have now to speak of the chalk red or Bartolozzi print colour. To produce this the procedure is very little different. Development should be carried further so that the faintest details are decidedly out, as the strength of the picture will depend altogether on the colour deposit, the unchanged silver being removed afterwards. For this colour it is advisable, also, to produce pluckier prints than are used in the brown process, as, if too soft, your deepest shadows are apt to look weak after the silver is removed. When this fully developed image is toned for a considerable time it will have attained a black-red appearance, as shown in the left hand section of this print. This appearance will present itself in fifteen to twenty minutes, but is desirable to let the action go on for an hour, as, at first, the colour deposit is only on the surface, and if the unchanged silver underlying this be then removed the whole of the force in the shadows would be lost. When it is judged that the tone has penetrated the deepest shadows the print is washed in running water for five minutes, or till the acid is removed, and is then immersed in a bath of Farmer's reducer. All the black heaviness dissolves out, and you have left something approaching a red chalk drawing. The hypo is now to be got rid of, and to effect this as speedily as possible I again resort to peroxide of hydrogen. A couple of minutes' washing before immersion in this bath, and five minutes after washing, will have freed the paper from the hypo. The immersion should also be for five minutes. If the high lights now seem to want clearing continued washing will have the desired effect, or, if you are impatient, add a little alkali to the water, and it will reduce quickly enough. If you use washing soda for this, or any other alkali in crystals, see that these are all dissolved before immersing the print, as, if any crystals touch the paper, the colour will be removed from the spot in contact almost at once.

For a dark green colour, which would give something of a night effect to a seascape, it is only necessary to place a toned print in a very weak solution of perchloride of iron and hydrochloric acid; but this I call playing pranks. I must warn you that it is rather fluky, and you may get a bright blue instead of a green.

I will not say more upon the chemical action involved in the uranium toning process than that a theory has been put forward by Mr. Levy, of the Photographic Club, in which he suggests that the ferricyanide of potassium combines with the silver image and forms a ferrocyanide of silver, with which the uranium nitrate enters into combination. I am not aware whether chemists accept this as the correct explanation, and no doubt the subject may still be forming the subject of investigation. It has, however, been proved by Mr. Haddon that there is no loss of silver when the toned image seems to have been washed away by long subjection to running water. Although a bright red-toned print—one, of course, from which the silver *has not been removed* by Farmer's reducer—may be washed out to a mere ghost. This ghost may be revivified by conversion into bromide of silver, exposure to light, and redevelopment, and may be again toned to any desired colour.

Mr. Haddon's Suggestions.

I have now described the process as I am in the habit of working it myself, and at this stage I wish to express my thanks to Mr. Haddon, of the London and Provincial Association, for his recent communication as to a means of improving the working of the uranium toning process. This is the first outcome of the appeal I made for help more than a year ago, for although many have tried to put forward other methods of toning bromides, Mr. Haddon has been the only one to make any practical suggestion for the improvement of the uranium method. The suggestions made by that gentleman were three: First, that by using an acidulated washing water the loss of tone in clearing the print would be done away with. Second, that by increasing the quantity of uranium nitrate to about five times the amount of the ferricyanide, the precipitate of ferrocyanide of uranium in the toning bath would be avoided, and a saving of precious metal effected; and also that the bath in that condition would be of good keeping quality. The third suggestion had reference only to the chalk red process. To avoid the reduction which may occur in removing the hypo used in that process, he suggests that the silver can be removed from the print by the substitution of sulphocyanide of ammonium and ferricyanide of potasium in place of Farmer's reducer.

To deal with the last suggestion first, I may say at once that I have not yet tried it. But it occurs to my mind that the sulpho-cyanide will have to be removed from the paper in the same way as the hypo, or if it be left without more than a few minutes' washing, I would like some one who knows to say whether its retention in the print would not set up some combination which might endanger the print. As regards this suggestion, I would say that the difficulty it is designed to obviate is more imaginary than real, as those who will practically work the process will immediately see, The red image, from which the silver has been removed by Farmer's reducer, is sufficiently hard to wash out as to be very little affected by the amount of washing required to be done in the way

I suggest. The full development of the image, in the first place, is not, as suggested by Mr. Haddon, for the purpose of allowing for washing out, but for the purpose of getting decided strength in the weakest detail, as they, when toned and the silver removed, would naturally look weaker in a faint red than they do in the original grey. By using the peroxide of hydrogen the hypo is so quickly eliminated or decomposed that there is little perceptible reduction in tone, and I have not found any one to positively state that the prints will suffer from the hypo eliminator if they have five minutes' washing in running water after they are removed from it.

Comparative Experiments.

Now, as regards Mr. Haddon's suggestion to wash after toning in water acidulated with acetic acid, with a view to removing the yellow stain without reduction of the tone, I have made a comparative experiment to illustrate to you the advantage or otherwise of this suggestion. I submit to you a print which has been toned to a red-brown colour, and from which section "A" was cut off and thrown into running water, and there remained for nine minutes, and then blotted off and dried. Sections "B" and "C" were washed in thirteen changes of acidulated water over a period of sixty minutes. Section "B" was then cut off, blotted, and dried, while section "C" was thrown into running water and washed for seven minutes, and then dried.

It will be observed that the yellow stain is not removed from "B," although it has been treated with constant changes of acidulated water for an hour, and that it is only when it has received a further washing of the usual time in plain water that the print is cleared. In the gaslight this is not so apparent as it is in daylight, but you can, I think, clearly see the marked difference between "B" and "C."

Now, on comparison of "B" and "A," it will be observed that "B," which was treated with acid, has decidedly suffered less loss of tone than the section treated only with plain water. This latter, however, I may say, received four minutes more washing than was absolutely necessary to remove the yellow stain, while "B" was removed from the water the moment the stain was sufficiently removed to make the high lights match with those of those of "A." On the whole, I admit an advantage for this suggestion; but it is so unimportant, and obtained at the expense of an extra expenditure of time, that, in my own practice, I shall probably content myself with the old method.

And now I come to the suggested alteration in the proportions of the constituents of the toning bath. This alteration is, no doubt, based on sound theory, and it is too soon yet to say whether, in actual practice, it will not result in some improvement. My experiments, however, so far do not give me such satisfaction as I anticipated from Mr. Haddon's suggestion. As you will observe from the bottle of solution I submit to you, and which has been made up according to the formula given, and used to tone four half-plate prints, there is not that absence of precipitate which was anticipated. There is, in fact, more precipitate than in a bath of the old proportions which has done nearly double the work. It may be urged, of course, that the one contained ten times more uranium at first than the other, but it was with a view to retaining that uranium in solution that this great increase was made. If the alteration be advocated on the score of economy, I think it is very doubtful if the aspirations of its proposer will be realised. The altered bath costs ten times more than the one made by my formula, and, even at that, is not a very ruinous affair, but when it is considered that an eight-ounce toning bath, made by my formula, will cost for uranium nitrate (2s. 4d. per ounce) exactly one farthing, it is scarcely worth while saving it after it has been used for a few prints. I should think it will be less trouble to put it down the sink. As to the keeping quality of the bath (Mr. Haddon's), my experiments are satisfactory. After keeping for eleven days, I toned a print (the fourth) in quite as short a time as was required for the third. The precipitate, however, further increased, and it is questionable if it will keep sufficiently long in use as to do the same proportion of work as could be done by ten fresh baths of the original composition. I have tried a bath of the altered proportions, diluted to the same strength of uranium as my formula; but, although it tones at first exactly the same as mine, it rapidly deteriorates. I have put on the blackboard a table showing the comparative time taken to tone six prints in succession at intervals of half an hour in each of the two baths, from which it will be seen that, whereas the first prints in each were toned to a standard colour in five minutes, the sixth prints took respectively twelve and thirty-two minutes.

Table of Results.

These two baths were again tried eight hours later, when the old bath toned its print to the standard tint in eight minutes; whilst the new diluted bath was found to be practically inert. Upon adding, however, sufficient ferricyanide to bring it up to the same composition as my formula, it toned a print in five minutes, and the amount of precipitate, as you will observe, is very slight indeed. No doubt it will do its work all right still, after a further lapse of forty-eight hours. We will probably try it when giving the little bit of demonstration with which I now propose to conclude this paper.

The toning bath, made by the original formula, and used for toning ten half-plate prints, was tried again, after a lapse of eleven days, and found to be practically useless. It took thirty minutes to produce the standard tint, but, as I have said, when it has done a fair amount of work, we can afford to throw it away.

The following table will show the relative rate of working of the three baths. The time taken to tone a print to a standard colour is stated in minutes:—

Uranium Nitrate	5 grains.	0·5 grain.	0·5 grain.
Potassium Ferricyanide	1 grain.	0·5 grain.	0·1 grain.
Glacial Acetic Acid ...	30 minims.	10·0 minims.	10·0 minims.
Water	1 ounce.	1 ounce.	1 ounce.
	Mins.	Mins.	Mins.
Print No. 1	2½	5	5
" " 2	3½	5	5
" " 3	5	8	13
" " 4 Eleven days later	5		
" " 4	... ...	10	15
" " 5	... ...	10	20
" " 6	... ...	12	32
" " 7 Eight hours later	... ...	8	Bath exhausted.*

J. Weir Brown.

CARBON PRINTING.†

Stages of the Process.

Carbon prints may be divided into three stages. Suppose that the requisite number of pieces of tissue have been exposed on the negatives:—

1. They are slightly soaked in cold water and squeegeed down upon some temporary support for development.

2. After remaining for a time in contact under slight pressure, the tissue and supports are placed in warm water, and when thoroughly soaked the outer skin of paper is pealed off and thrown away, leaving, the print of the face of the support, but buried in a mass of dirty gelatine, which has to be washed away to expose the true prints, and which, when cleansed from all insoluble gelatine, shows a reversed print on the temporary support. This is placed in a solution of alum, to harden the gelatine and extract any trace of bichromate which may be left on the film. This shows a perceptible tint in prints developed on a flexible support, but is almost invisible when working on opal glass. After a wash in water to extract alum, it is dried and completed.

3. The reversed image has now to be transferred to its final support of paper, or any other material which may be desired. The print on the temporary support and the paper for transfer are placed in warm water and brought into contact, squeegeed together and allowed to dry spontaneously, when the picture will leave the support of its own accord and become firmly attached to the paper, and is ready for mounting in the same way as any ordinary silver print.

That is the process known as the "double transfer;" but where reversed negatives can be made, or ordinary negatives can be stripped from the glass and printed from the reverse side, or where film negatives are used, the process is more simple and expeditious, because the tissue can be squeegeed at once upon its final support-paper, and when developed and dried it is finished; but in such case the gelatine is exposed on the surface of the print, and the general effect is a glazed surface somewhat resembling lightly albumenised paper, and you fail to obtain the perfectly matt surface which results from the double transfer upon smoothed opal or ground glass, which has been previously waxed, when the print shows a softly grained matt surface, which is exceedingly like the face of a platinotype print.

The final result, as regards face of print, depends entirely on the surface of the temporary support. If such support is a sheet of polished glass,

* On the addition to this bath of a quarter of a grain of ferricyanide of potassium per ounce of solution, a print is toned five minutes. This, no doubt, proves the value of one of Mr. Haddon's suggestions, and that by the addition of the ferricyanide little by little the last trace of uranium in the bath may probably be utilised.

† Continued from page 122.

previously waxed and coated with collodion, the result will be a highly polished enamelled print; but if, as I shall show to-night, the support used be of smoothed opal glass, the result is a beautiful matt surface, and I consider that there is no form of carbon printing which is so convenient to work and so delicate in finish as this, and that it fully repays for the slight extra trouble of working the double-transfer process.

Of course, the tissue can be squeegeed at once upon opal glass, developed, and dried upon it, and thus becomes a fixture, which can only be got off by some grinding process, but will be a reversed print, unless it is developed on some flexible temporary support, such as is supplied by the Autotype Company, and then transferred to the opal.

I will now proceed to the first portion of the process, and attach to the opal glass the tissue I have exposed to-day, and, whilst the water bath is being raised to the necessary temperature, I will make a few more remarks.

A Critical Point.

Note that there is just one critical point in this attachment to the opal. It is necessary to watch very closely the state of expansion of the tissue. If squeegeed down too soon, it will not lie flat, and if left to soak too long the adhesion will not be perfect, and is apt to strip up and come away from the support in taking off the paper, or in development. If the dry tissue is fairly dry, on contact with the water it has a tendency to curl inwards towards the gelatine; as it absorbs moisture it flattens out, and if left long enough will eventually curl outwards, but it must be taken at the moment when it is just flat enough to lie evenly on the support, and before it curls outwards, when the attachment is perfectly safe for the after-operation. I prefer to work in a tank of sufficient size to take two prints—one to soak the paper off, and one to go on developing, as time is thus saved. Indication of the softness of condition for stripping is seen by the oozing of the gelatine from the edges, and sometimes of blisters forming between the paper and support; but care must be taken not to attempt to strip it too soon, or the print may be lifted from the support and spoiled.

The Autotype Company, in their *Manual*, advise the temperature of the water for development to be raised to 100° to 110°. This may be all right for tissue, which is attached to a final support of gelatine paper, as the adhesion is very strong; but, in using a fine-grained waxed support, I find a great risk of blistering the tissue, and that a temperature of 96° to 100° is much safer and better, though somewhat slower in action; but I find it produces better half-tone, as there is less tendency to boil away the delicate skin of gelatine where it is at its thinest texture, viz., in the high lights and lighter half-tones.

90° is described on the thermometer as "warm water," and 106° as "hot water," and I find it becomes unpleasantly hot to the hands inside of indiarubber gloves when it gets up to 110°.

(To be continued.)

A NEW LANTERN MICROSCOPE.

By courtesy of the London Stereoscopic Company, we have had an opportunity of inspecting a new projection microscope, invented and made by Mr. R. G. Mason, which should be welcomed by science teachers, lecturers, and all who use the microscope for lantern projection as well as for ordinary direct examination of either opaque or transparent objects. We have been furnished with a comprehensive account of its construction and uses, from which it appears that it is not only a lantern microscope, but possesses the advantage of being instantly, and without loosening a screw, convertible into a student's instrument for table use.

When adjusted for projection work, the microscope consists of a brass tube, with screw to fit the flange of an ordinary optical lantern. Inside this slides another tube, carrying at one end a parallelising lens, and at the other the sub-stage condenser; this can be slid to and fro, so that the object can be illuminated as desired.

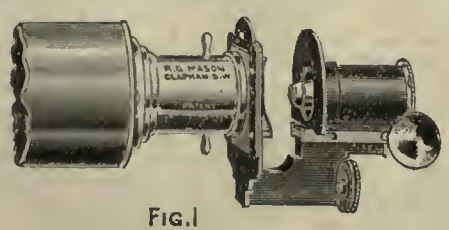

Fig. 1

In the instrument under notice an addition has been made in the shape of a polarising apparatus, by means of which the Nicol's prism may be rotated entirely by means of a milled head fixed at the side. A fixed stop indicates when a complete revolution has been made. An extra socket is supplied to hold the second prism in front of the objective, and this has also an indicator, to show the amount of rotation. The sub-stage condenser is of the standard size, and the fitting is, therefore, available for use with any sub-stage appliances the student may already possess. The stage is furnished with the ordinary wheel of diaphragms and a neat and practical object-clip of entirely novel construction, the arms being lifted by pressure on a small thumb-piece, while the object, which may be a thick zoophyte trough or a thin piece of paper, is slipped under them.

When great magnification is required while using a low power, an amplifying lens is used, mounted to slide into the front of the objective carrier. Two kinds, suitable for projection and photo-micrography respectively, are issued with the instrument. For photo-micrography nothing more is necessary than to fit the instrument to an ordinary camera, supported in any convenient way. The milled head of the fine adjustment has a deep groove cut upon the edge, so that a small band may be placed upon it and connected with a grooved wheel and rod running under the camera, to permit of accurate adjustment on the ground glass.

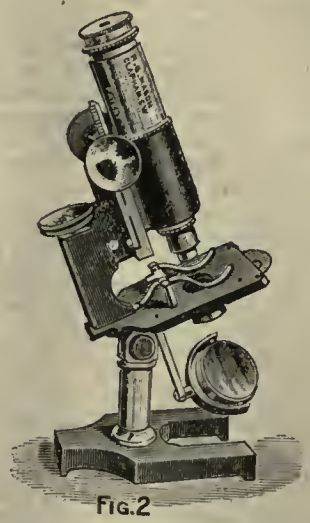

Fig. 2

When required for use as a table microscope, the stage is slipped off it lantern attachment and slipped on to the foot, which is of the ordinary pattern. The way in which this is done is very simple; the stage is, so to speak, split into two layers, one of which is permanently attached to the lantern fitting, and an exact duplicate to the table stand which carries a standard sub-stage fitting; the other layer, which is really the stage proper, is fixed to the body of the microscope in the ordinary way, and can be slipped into grooves in its counterparts for either purpose. These grooves, as well as all other working parts of the microscope, are compensated, so that with fair usage it is almost impossible for wear to impair its usefulness. The rack of the coarse adjustment is spiral, so that there is always contact during movement, while the fine adjustment is made with the usual very finely threaded screw. The draw tube permits of extension to the full English length, and can be so placed as to permit of a four-inch objective being used, if desired. Any objective may be used, but Mr. Mason prefers to supply a special form, which, while having large aperture, gives sharp and clear definition to the edge of the field.

ELEMENTARY NOTES ON PHOTOGRAPHIC LENSES.*

Flatness and Curvature of Field.

Flatness of field is the power of bringing the rays from equally distant objects to a focus in a true plane. No lens is perfect in this respect, the margin of the picture being well defined nearer the lens than the centre, as in diagram 5, the curve representing the points of greatest sharpness. If the field were absolutely flat, the marginal ray would be as shown in dotted lines.

To test or compare lenses for flatness of field, arrange the camera so as to have some well-defined object, such as a leafless tree, in the centre of the plate; then, when this has been focussed as sharply as possible, make a pencil-mark on the moving part of the baseboard, and then revolve the camera on the triped-head until the same object is seen at the edge of the plate, when it will be decidedly out of focus. Refocus, and make a second pencil-mark, the distance between the two being the curvature of the field. This is one of the points in which the greatest

* Continued from page 126.

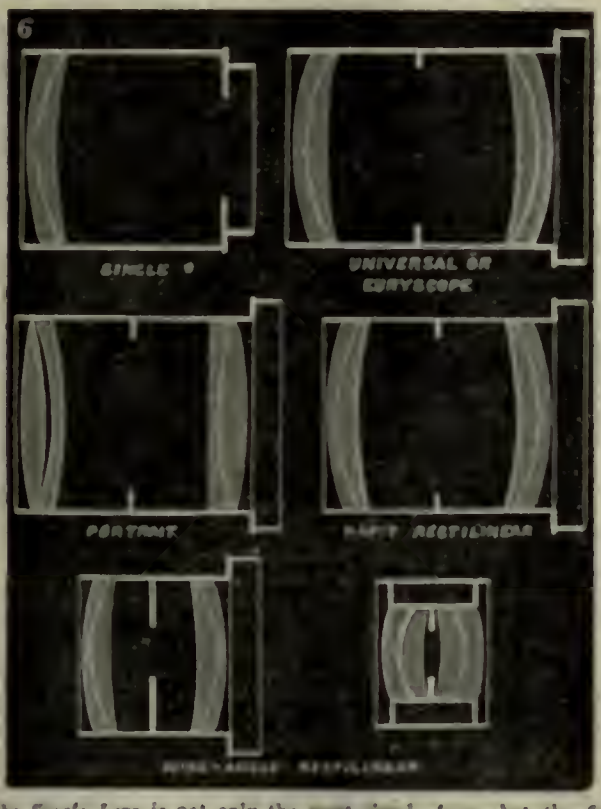
difference exists between good and inferior lenses, some having fully double the curvature of others.

This curvature of the field may, in some instances, be utilised, and almost amount to an advantage. In photographing an interior, the sides of the building being nearer the lens than those parts forming the centre of the picture would be, as I have previously shown, in sharp focus

farther from the lens, or beyond the curve in the diagram, either between the curve and the plane, or even on the plane itself, as shown by the dotted lines. In taking groups or subjects within the photographer's own power of arrangement, knowing that this defect exists, the sitters near the ends should be placed rather nearer the camera than those in the centre, when it will be much easier to get all the faces well defined.

The Single Lens.

Sections of the principal types of lenses are given in diagram 6.



The Single Lens is not only the most simple form, but the finest possible for landscape work. It consists, generally, of two glasses, occasionally three, cemented together, mounted at one end of a tube, the stop being at the other. They are most frequently concavo-convex, this form being termed "meniscus," and sometimes plano-convex. The convex side is always nearest the sensitive plate, the stop being at the concave or flat side.

The great value of a single lens is that it gives a more brilliant and vigorous image than any other form. For this there are two reasons. First, being one combination only, there are fewer surfaces to reflect stray light than in others; and, second, being at the back of the tube, it is well protected from diffused light, only those rays striking the lens that are utilised in forming the image. Unfortunately, it has corresponding disadvantages, the most important being its distortion.

It is an inherent defect in all single lenses to produce a distorted image, *i.e.*, one in which true projection is not obtained, straight lines near the margin of the picture being reproduced as slight curves, as in diagram 7, the curvature being outwards as A if the stop is in its usua

position on the outside of the lens, and inwards as B if the position were reversed, or the stop inside.

While these curves are greatly exaggerated in the diagram, yet they are sufficiently pronounced to render the lens useless for ordinary architectural or true copying work where straight lines may occur close to the edges of the plate. In many instances, however, by judiciously arranging the subject so as to keep long straight lines well away from the margins, this distortion will be inappreciable. In landscapes or figure subjects, this slight distortion being of no importance whatever, full advantage may be taken of the merits of this type of lens.

Its second disadvantage is that it cannot be used without a stop, and is consequently much slower than those that allow of their full diameter being utilised for each cone of rays. By the defect known as spherical aberration, if the full diameter is used, the margins do not bring that portion of the beam of light passing through them to a focus at the same point as the part that passes through the centre, but rather nearer the lens, and so crisp definition cannot be obtained until a stop is so placed as to cause a central ray to pass through the centre of the lens only, and marginal rays through its edges. A good single lens that is well corrected for this defect will generally give fairly good definition with a stop half its own diameter.

There is an incidental advantage in this necessity for the lens being so much greater in diameter than the largest stop, the plate is very evenly illuminated, much more so than with any other form of lens.

Its rapidity is ample for most outdoor work, and for such I should strongly advise its selection preferably to any other. In many cases, beginners are taught to somewhat despise a single lens, and consider it a thoroughly inferior article to a rectilinear; they are told that "it will do to commence with, they can get something better later;" but, as their acquaintance with photography extends and their powers of discrimination increase, they will be very unwilling to substitute any other. The editor of The British Journal of Photography, an eminent authority on photographic optics, in an article on this subject, said, "Some of the finest landscapes the world has ever seen have been produced by this lens."

The Portrait Lens.

The portrait lens is, to an amateur, the most useless form possible. Originally introduced in the days of collodion, when plates were much slower than at present, its great object was to reduce the time of exposure as much as possible; but to obtain its great rapidity every other good quality has to be sacrificed. It is a double combination, a plano-convex cemented element at the front of the tube, and at the back a double convex and a concavo-convex, with this peculiarity that, instead of being cemented together as usual, there is a small air space between them. In this, as in all other double forms of lens, the stop is placed between the combinations.

Many amateur photographers have imagined that there is some unique property in a portrait lens, rendering it specially capable of taking portraits, or that they could not be taken so successfully with any other. This is a fallacy; its only advantage is its rapidity, and this is so great that it is quite unmanageable, for most outdoor work, unless considerably stopped down, and then any other lens is better.

Amateur portraits are mostly best when taken out of doors, as the softness of lighting necessary can be so much more satisfactorily arranged than in any ordinary room, and for this any landscape lens is specially suitable.

The disadvantages of the portrait lens are, the field is very round, and it has more reflecting surfaces, this last being a very serious objection. It is probably familiar to every one that, when a gas flame is reflected in a mirror, in addition to the principal image, two or more others somewhat fainter are seen, which are principally reflections from the front unsilvered surface of the glass, and multiplied reflections from the two surfaces. A similar species of reflection is constantly occurring in photographic lenses, and, though not always in the form of a visible

image, it is frequently present in a diffused form, detracting from the brilliancy of the image. In very extreme cases, such as a very dark interior, with a bright window at one side, or even a view in which one side of the plate is occupied by a dark mass of foliage, and the other by a brilliant sky, a lens that possessed this reflecting capacity very strongly marked would produce a "ghost," or faint diffused image of the bright object on the dark side of the view.

Where two glasses are cemented together, these faces in contact do not reflect—it is only the surfaces that are exposed to the air. It will be seen from the diagram of the portrait lens that it has six such surfaces, four of these being concave towards the plate, which seem to be far more active in producing these reflections than those that have their convex side towards it; and so strong is the tendency of this lens to produce "ghosts," when used with stops especially, that it is practically impossible to use it for most outdoor work.

H. W. BENNETT.

Our Editorial Table.

FLASHLIGHT PICTURE.

By J. G. HUDSON, 4, Randolph-gardens, Maida Vale, W.

AT the conclusion of the meeting of the National Association of Professional Photographers, at Anderton's Hotel, on Thursday, February 11, Mr. J. G. Hudson (of the "Kolm" lamp) took a flashlight negative of the members, prints from which are now before us. The results are most successful. Mr. Hudson informs us that he is willing to supply copies at 1*s.* 6*d.* each, and that the proceeds of such sale will be handed over to the Photographers' Benevolent Association.

MR. W. TYLAR, of Birmingham, sends us a small pamphlet of eight pages devoted to a description for beginners of the art of photographing microscropic objects. It is clearly written.

MESSRS. W. B. WHITTINGHAM & Co.'s Photographic Price List comprises within its 150 pages descriptive details of the innumerable requisites demanded in modern photography.

THE second number of the *Idler* (Chatto & Windus) contains another instalment of "Choice Blends," a series of composite photographs by Boning & Small, of not wholly dissimilar persons, such as Colonel North and Mr. Burns, Mr. Grossmith and Lord Halsbury, Mr. Labouchere, and Mr. Yates. Many of the other illustrations to the magazine are of the singular quality known as "impressionistic." They do not favour the artists, who, in their turn, have little cause to be grateful to the process of reproduction. As for the literary matter of the *Idler*, that part of it which is meant to be witty is dull and forced, and the remainder has a distinctly "spectral" flavour. Remove the big names from its titlepage, and the contents as literature, or even humour, could not possibly produce any other impression than that of the commonplace.

WE have received the ANNUAL REPORT AND PROCEEDINGS OF THE PHOTOGRAPHIC CLUB for 1891. The condensed discussions upon a great variety of subjects, which are given in the volume, are a mine of valuable information. A paper *On the Theory of Development*, by Mr. A. M. Levy, which is printed *in extenso*, is a most able examination of the subject, and its restriction to the Club's proceedings is a loss to photography.

THE OPTICAL LANTERN AS AN AID IN TEACHING, by C. H. Bothamley, is a reprint of some articles published in a contemporary. As an introduction to lanterniana, the *brochure* is all that could be desired. It is published by Messrs. Hazell, Watson, & Viney.

FROM Messrs. Mawson & Swan we have received quite a parcel of useful little publications, comprising *An Exposure Note-book*, *A Set of Labels for Photographers*, *How to make Transparencies*, *The Wet-collodion Process for Iron Development*, and the *Gelatino-bromide Paper Process*. Herein will be found a number of practical hints likely to be of material assistance to the amateur in the various processes dealt with.

ANLEITUNG ZUR PHOTOGRAPHIE FUR ANFANGER, by Captain Pizzighelli (Halle, Wilhelm Knapp), is now in its fourth edition. It is an exhaustive and practical treatise on photography, small in bulk but rich in value, and contains no fewer than 166 illustrations of apparatus.

PATENTS COMPLETED.

IMPROVEMENTS IN PHOTOGRAPHIC CAMERAS KNOWN AS "DETECTIVE," OR HAND CAMERAS.

No. 4459.—JAMES W. MORGAN, 35, Princes-street, Tunbridge Wells, Kent. *January* 30, 1892.

THIS invention relates to improvements in photographic cameras of the character known as hand cameras, or "detective" cameras, and has for its object to simplify the construction of such cameras, and reduce their size, and for other purposes.

According to my present improvements I arrange and construct a camera as follows :—

The case or frame of the camera is of any suitable shape; but, for the sake of example, I will describe an oblong box or case.

The lens is, or may be, mounted on a sliding plate, sliding in grooves or bearings inside of the case, such slide being actuated in any convenient manner —for instance, by a knob or handle projecting through the case, by which also it is secured in the desired position, a pointer on such knob or handle serving also to indicate (on a scale or dial provided) the distance the lens is set for.

Any usual or suitable shutter may be used, and also any usual or suitable view-finder may be used.

The sensitive plates or films are mounted in sheaths or plate-holders, and are placed in position at the back of the camera, to which admission is gained by any suitable door or opening provided for that purpose.

All the plates when in position are pushed forward by a spring in the back of the camera, which spring is controlled by, and can be drawn back by, means of a knob, or the like, projecting through the back end or side of the camera, as and for the purpose hereinafter explained.

The front plate is thus pressed firmly up against a beading or sort of frame, where each plate in turn takes its position for exposure.

The front plate, after exposure has taken place, is then allowed to drop through a transverse slot in the bottom of the case by simply withdrawing the pressure of the aforesaid spring and shaking the camera, and the said exposed front plate will then drop through the slot into a light-tight bag or case made of any suitable fabric or material, which case is made just large enough to hold said plate, and is attached to a slide which travels in guides, or is so held that it can travel freely backwards and forwards (within a certain limit) in line with the plane of the bottom of the camera case, and in the direction of its length.

The slide with the attached bag containing the exposed plate is now slid back until the bag and slot in the slide coincide with a second slot in the bottom of the camera case; the camera is then turned upside down, the aforesaid spring at the back is again drawn back, and the exposed plate drops out of the bag back into the camera, right at the back of all the other plates, and so on with each successive plate, until all have been exposed. The bag, when out of use, lies flat against the bottom of the camera.

To indicate how many plates have been exposed, so as to show when all have been exposed, and prevent exposing by accident any of the plates a second time, I have invented the following device :—

The carrier or sheath of the last plate to be put in the camera (when filling same in the dark room *et cetera*) has a lug or projecting pin, which is inserted in the eye of a sliding dial or indicator, which it pushes forward when each plate in front is changed to the back, and through an aperture in the case successively indicates the number of the plates exposed (or not exposed, as desired), and, when it ultimately reaches the front position, and has been exposed, it cannot be removed through the aforesaid slot, as the said pin or lug prevents its dropping out through the slot in the bottom, and hence unmistakably indicates that all the other plates have been exposed.

I wish to remark that I do not limit myself to the use of any particular shutter and apparatus in connexion therewith, as any shutter suitable for the purpose may be used as desired.

IMPROVEMENTS IN AND CONNECTED WITH PHOTOGRAPHIC CAMERAS.

No. 21,605. RUDOLF STIRN, 34, Sebastianstrasse, Berlin S., Germany.—*January* 30, 1892.

THIS invention relates to a photographic camera in which the plate exchange, in contradistinction to the corresponding devices of other known cameras, is effected in the exposure chamber.

The light-sensitive plates are each arranged in a peculiarly constructed sheet-metal case or frame, and are laid one above the other in the plate chamber, separated from the exposition chamber by a partition which, in order

to permit the insertion of the plate to be exposed and the removal of the exposed plate, is at its superior and inferior side provided with an appropriate slot.

The movement of the plates to and from the exposing chamber, out of the plate chamber and back again into the same, is effected by means of two slides connected by bands running over suitable rollers, so that both slides move simultaneously but in opposite direction.

The lower slide effects the feed of the lower plate of the series from the plate chamber into the exposition chamber, and the upper slide, the withdrawal of the exposed plate into the plate chamber and deposits the same on the series of plates.

A full exchange of plates, *id est*, feeding in a plate, adjusting the same in the focal plane, and removing the same after the exposition into the plate chamber, is effected by twice operating the lower slide. The second movement of the slide effects the removal of the exposed plate, and the feed of a further plate from beneath the series of plates into the exposition chamber, which, on pushing back the slide a second time, is placed into proper focus, whilst the exposed plate is deposited in the plate chamber, and the upper slide brought into a position for removing the next following exposed plate when the lower slide is pushed in.

Meetings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

FEBRUARY 23.—Technical Meeting.—Mr. T. Sebastian Davis, F.C.S. (Vice-President) in the chair.

The CHAIRMAN stated that the Council had appointed Mr. H. Chapman Jones, F.C.S., to be Hon. Secretary of the Society. He also announced the death of Mr. Edwin Cocking, formerly Assistant Secretary of the Society, and said that, having been associated with him for a number of years, he felt the sudden separation keenly. He referred to the extreme personal interest exhibited by Mr. Cocking in the prosperity of the Society during his fifteen years' office, more especially with reference to the annual exhibitions. The Council had voted an expression of sympathy with the family.

Mr. J. SPILLER joined in the Chairman's expression of sympathy, and said that Mr. Cocking had worked for a great number of years in the interests of photography and photographers. Those who, like the Chairman and himself, had worked so long with Mr. Cocking felt deeply for the family in their bereavement.

Mr. Chapman Jones having brought the old and new forms of Sawyer's actinometers for the inspection of members, and compared their respective merits,

Mr. W. SWAN said that the old form of Johnson's actinometer was probably more useful than the recent one, especially for carbon and platinum printing.

Mr. SPILLER asked whether the paper was first sensitive to the tints in the dry state when moisture was present.

Mr. H. A. LAWRANCE quoted from Eder's experiments, proving that bichromated gelatine in the dry state was insensitive compared with it when it was wet and moist.

Mr. T. SEBASTIAN DAVIS exhibited a modification of his printing frame, designed to obviate the shearing action caused by the movement of the springs. Catches placed at each side of the frame prevented movement of the paper by holding the back of the frame in its place, and allowing the springs to be moved without altering the position either of the back or the paper.

The subject for discussion was *The Relative Merits of Different Processes for the Production of Lantern Slides*.

The CHAIRMAN said he had been much struck by the beauty of the slides prepared by the ordinary wet-collodion process by Mr. P. H. Fitzham. Absolute clearness in the high lights was not to be expected with modern processes. With gelatine there was a certain tendency to slight haze in the more transparent parts of the picture; with wet collodion there was not the slightest tendency of that kind. Comparing one thing with another, the brilliancy of gelatine slides was not equal to wet collodion. He also spoke of the advantage of isochromatic plates in certain branches of photo-micrographic work.

Mr. A. COWAN said that with gelatino-chloride the high lights were as clear as gelatine and glass could make them. Bromide plates would give the same results if they were slow enough.

Mr. T. E. FRESHWATER always used wet plates where possible, as in his hands the process was much the simpler, and certain in its results. For contact work he used all sorts of commercial plates. He had tried the new developer, rodinal, and found it gave clearer shadows than the other developers. He agreed with the Chairman that isochromatic plates were a great advantage in photo-micrographic work. He always toned his wet-plate slides with gold.

Mr. CHAPMAN JONES asked whether the clearness said to be given by wet collodion was necessary? He thought it might conduce to a great amount of hardness.

Mr. J. D. ENGLAND showed a number of slides on gelatino-chloride plates having great clearness, and showing different colours, obtained by lengthening the exposure and restraining development. He also exhibited Scanlan's metal holder for film lantern slides. In reply to a question, he said he got just as good slides on films as on glass—in fact, he could detect no difference.

Mr. T. SAMUELS said, if he made his own slides, he should use the wet-collodion process in preference to any other, as by that process the best results could be got from inferior negatives. It had been said that wet-collodion lantern slides were sometimes hard. Probably it was so with under-exposed negatives. A great point with over-exposed negatives, useless for printing purposes, was that, by timing the exposure and regulating the development and intensification, excellent slides could be made by wet collodion, which was a great advantage. If one had good negatives, good slides could be made on commercial plates; but, unless the negative was good, they were unable to get the same result with gelatine as with collodion. Lantern slides by contact could also be made with wet collodion by using paper to keep the film from the negative. A nice, soft picture resulted, the "diffusion of focus" being very pleasing. He would give the preference to wet collodion, because there was no doubt about the permanence of collodion slides, and, besides, they could be toned.

In reply to a question, Mr. T. R. DALLMEYER said crisper definition by copying than by contact could be obtained, particularly in reducing; a rectilinear lens answered the purpose, it was only a question of exposure.

Mr. CHAPMAN JONES said that some people thought that in exposing by contact they got a certain quality of slide by using magnesium, not obtained by gaslight or daylight. Was that so?

Mr. T. C. HEPWORTH said a deal depended on the colour of the negatives. If they were yellow, there was a decided gain in using magnesium, especially with chloride plates.

The CHAIRMAN said that in illuminating microscopic objects they occasionally had a great amount of detail and little contrast, and in photographing them it was difficult to obtain contrast in the light and dark portions of the picture. If they reduced the light considerably, they got a much more even image, and the contrast became increased. The difference was obtained by simply altering the position of the lamp, and it was analogous to the different effects produced by printing in full sunshine and in shadow.

Mr. T. R. FRESHWATER said that the whole secret of photo-micrographic work was that the object should be properly lighted. The light wanted modifying to suit the objects.

Mr. W. ENGLAND said that for copying he would use both wet and dry plates from a business point of view; but, simply as an amateur, he would not touch wet plates. He thought that practically as good results could be got with the one as with the other, though perhaps with wet plates there was a greater range of power, because from inferior negatives, as had been pointed out, better results could be obtained.

After some further discussion the meeting terminated.

Camera Club.—February 18.—Mr. S. B. WEBBER read a paper upon *Orthochromatic Photography*. Captain Abney occupied the chair.—The lecturer gave an account of some experiments in photographing certain subjects, including stained-glass windows and old documents, and described his method of preparing and treating the plates in orthochromatic work. A number of slides of the different subjects was shown and described illustrative of the lecture. March 3, a complete demonstration of the carbon process will be given by the Autotype Company.

Holborn Camera Club.—February 19, Mr. T. O. Dear in the chair.—Samples of Eastman's extra-rapid bromide paper were distributed amongst the members present. A representative of the Incandescent Gaslight Company, Limited, demonstrated the use of this form of gaslighting as applied to the optical lantern. The light seemed very powerful, and was, without doubt, a long way ahead of the oil lamp for use in the lantern. Next Friday (February 26), American slides.

Lantern Society.—February 22.—Three sets of slides, which had been made from three different 12×10 negatives, each set consisting of seven slides by seven different processes, were submitted for comparison. Two lanterns, each having the same kind of lenses and condensers, and arranged to give equal-sized pictures with an equal amount of light, were used. Two slides from the first set were then shown on the screen, and, the best having been selected by the audience, the other one was removed and a third slide substituted, and so on, until the best of the seven was finally selected. The same process was then gone through to get the second best; and so on with all the seven. This was done with all three sets. No information whatever was given to the audience concerning the slides, either as regards the maker's name or the process, until the judging was finished, when it was found that the order of merit was as follows:—*First Set*: 1. Collodio-bromide (Ackland); 2. Gelatine; 3. Wet collodion (York); 4. Wilkinson; 5. Collodio-bromide (Brooks); 6. Albumen (Levy, Paris); 7. Collodio-albumen (Ackland). *Second Set*: 1. Collodio-bromide

Ackland); 2. Gelatine); 3. Wilkinson; 4. Collodio-albumen (Ackland); 5. Albumen (Levy, Paris); 6. Collodio-bromide (Brooks); 7. Wet collodion (York). *Third Set:* 1. Collodio-bromide (Ackland); 2. Gelatine; 3. Wet collodion (York); 4. Albumen (Levy, Paris); 5. Collodio-bromide (Brooks); 6. Wilkinson; 7. Collodio-albumen (Ackland). The agreement between the two best slides in each set is worth noting. A new spirit set by Mr. Turnbull, of Edinburgh, and a lantern-slide printing frame by Mr. Dove, of Sandown, Isle of Wight, were exhibited; also a new projection lens, by Wray, of nine inches equivalent focal length and two and a quarter clear aperture of back lens, which gave most admirable results. This lens is corrected for photographic work as well.

Polytechnic Photographic Society.—Some prize lantern slides were shown. It was suggested that these exhibitions would be very much more valuable if the size of the original negative, method of preparing the slide, &c., were given, instead of having only the titles of the pictures, as in the present instance. March 4, *Flashlight Photography*, by Mr. T. Paternoster.

North London Photographic Society.—February 16, 1892, Mr. J. Traill Taylor in the chair.—Mr. A. MACKIE reported that, under the rules governing the affiliation scheme of the Photographic Society of Great Britain, the Society was entitled to send two delegates to the Committee, and Mr. E. W. Parfitt was accordingly elected to act as second delegate. Mr. J. WEIR BROWN then read a paper *On Uranium Toning of Bromide Prints* [see page 133], dealing very fully with the discussions which had taken place since he introduced the process, and the various modifications which had been recommended. In the result, he was disposed at present to prefer the process as he originally recommended it, although some of the alterations suggested would possibly be of assistance when more fully tested by experiment. The paper was followed by a demonstration, in which a number of bromide prints were toned under varying conditions, and a cordial vote of thanks was tendered to Mr. Weir Brown at the close of the discussion which resulted from the paper. Bromide prints were shown by various members. Next meeting, Tuesday, March 1, *Platinotype Printing*, by Mr. J. Martin. Visitors are invited.

North Middlesex Photographic Society.—February 22, Mr. J. W. Marchant (President) in the chair. Mr. T. SMITHIES TAYLOR, of Leicester, delivered a lecture on the *Use and Design of Photographic Lenses*, fifty-four members and friends being present. Mr. Taylor dealt with the subject in a most lucid and concise manner. Beginning by illustrating the progression of the waves of light by comparing them to the motion communicated to a rope, when the long, slow waves represented red light, medium waves yellow, and short, rapid waves blue, he followed on by showing diagrams by means of the lantern, explaining that light proceeded from its source in a succession of hollow shells or spheres; the manner in which a minute ray of such a wave of light would be transmitted by a pinhole, or larger quantities of the wave would be condensed by a lens to form an image. In this connexion he used and amplified Professor Sylvanus Thompson's illustration of a line of soldiers marching forward, and encountering rough ground in their course, showing how the line of march would be altered by the obstacles met, and showed the similarity of effect when the waves of light meet a dense medium, in their passage through the air, in the shape of a lens. Having dealt with the principles involved, Mr. Taylor conducted his audience with equal esse through the bewildering varieties of lenses, explaining the suitability of each for its special purpose, and its disadvantages for others. Samples of lenses in various stages of preparation were shown, and the general methods of production explained. In answer to a number of questions, Mr. Taylor supplemented his lecture by dealing with standard tests for the desirable qualities in lenses which might be applied by photographers—*e.g.*, for flatness of field, definition, spherical aberration, mechanical perfection of surface of lenses, centering of lenses in the mounts, ratio value of stop in single and R. R. lenses as compared with their actual diameter, and the coincidence of visual and chemical foci. On March 14 Mr. Walker will have a chat with beginners on *Photographic Procedure*.

South London Photographic Society.—February 15, the President (Mr. F. W. Edwards) in the chair.—Specimens of work with the rodinal developer were shown, and the merits of it were discussed. The following proportions were found to give better results than those advised by the manufacturers:—One part in twenty-five parts of water for negatives, one in forty-five for lantern slides and transparencies, and one in sixty for bromide paper. The PRESIDENT brought to the meeting a large number of prints from isochromatic and ordinary plates, and explained the occasion on which the use of the former was advantageous. Mr. Miller exhibited some prints from negatives taken on Britannia plates which had been kept at the Cape for over twelve months before use. The platinotype paper used was over two years old, and the results were quite equal to any which can be obtained on fresh plates and paper. The competition for the best print on bromide paper had but few entries. Mr. Whitby was declared to have produced the best results. Messrs. Whittingham & Co. showed their new pattern cameras for the coming season.

Brixton and Clapham Camera Club.—February 18, Dr. J. Reynolds in the chair.—Mr. Crouch, who had been announced to deliver a lecture *On Lenses*, had telegraphed at the last moment to say that, by his doctor's orders, he was confined to his house. An *impromptu* question box was made of the Chairman's hat, and various remarks and difficulties, which had occurred to members, were discussed.

Lewisham High Road Camera Club.—February 19, Mr. H. Davis in the chair.—Professor CARLTON J. LAMBERT, M.A., gave a lecture *On Light Measurement*. He showed the difference between the visual, actinic, and heating effects in the spectrum, and explained the cause of colour blindness. The following tables, by Captain Abney, showed how rapidly the actinic value of sunlight falls off as the sun's altitude decreases:—

	Candles at 1 foot.	Actinic.
Sunlight—June, overhead—visual	5500	120,000
30° altitude	4700	72,000
20° ,,	3300	42,000
10° ,,	2000	9,000
Before sunset	140	1·7

Professor Lambert tested the tables on February 18, 1892, when the sun's altitude was 20°, and found the visual effect equalled 2700 candles at one foot. The following is another table, by Abney, of actinic values:—

1 visual candle of sunlight	= 20	ordinary candles.	
,, ,,	electric arc = 10·7	,,	,
,, ,,	magnesium = 2·5	,,	,,
,, ,,	limelight = 2	,,	,,

Professor Lambert found that 20-candle-power gaslight gave a print on albumen paper in 27 hours. Captain Abney found a trace of a print on platinum paper in 20 hours. When there is a very bright moonlight night, people are apt to say that it is almost as bright as day. To show how ridiculous that is, Professor Lambert found that full moonlight in February = 1 candle at 10 feet, and that full sunlight in June = 550,000 such moons, which would cover the whole vault of the sky five times over. By means of photometers he compared different kinds of lights with a standard 16-candle-power Argand. Vulcan petroleum lamp = 30 candles (badly trimmed); limelight (blow-through jet) = 107 candles (gas was running short, or it would have been 150 to 200); Welsbach incandescent, with special mouth = 60; small incandescent electric lamp, lighted by 9 E.S. dry batteries = 1¼. He explained the method of comparing sunlight with standard candle by means of a rotating disc, with section cut out measuring ¼ part of sunlight; this was compared with magnesium light directly, and the magnesium compared with a standard candle. It is worked out in the following manner, viz.:—¼ sunlight = magnesium at 2 feet = 200 candles at 2 feet = 50 candles at 1 foot. ∴ sunlight = 54 × 50 = 2700 candles. Thia is how the result, stated as obtained on February 18, 1892, was arrived at. Abney's corresponding figures for same at 20° elevation were 3300. The following tables have been worked out by Professor Lambert, the cost of electric light being obtained at the Crystal Palace Electric Exhibition, so are right up to date:—

EFFICIENCY OF GAS-BURNERS.

	Candle Power. Standard Candles.	Consumption. Cubic ft. of Gas.	Efficiency. Candle Power per Cubic foot.
Common Bray, No. 2	3	3	1
,, ,, No. 5	9	6	1·5
,, ,, No. 7	14	7	2
Bray's Special Batswing, No. 9	20	8	2·5
London Argand	16	5	3·2
Albo carbon	20	3	6·6
Wenham	90	10	9
Welsbach	36	3	12
Gas engine, driving dynamo and 100 incandescent lamps	3200	400	8

DOMESTIC LIGHTING.

Annual cost of maintaining a light of 48-candle power, say, 2000 hours' burning. Results of tests under practical conditions:—

Gas.

Argand.—Three 16-candle lamps, consuming each 5 feet of gas per hour = 30,000 cubic feet of gas, at 3*s.* per 1000, 90*s.*; renewals of chimneys, 3*s.*:—Total, 93*s.*

Wenham Regenerating.—One small Wenham lamp, consuming 6 feet per hour = 12,000 cubic feet of gas, 36*s.*; repair of lamps, &c., 5*s.*—Total, 41*s.*

Albo-carbon.—Two No. 2 Bray burners, consuming each 3½ feet per hour, carburetted with naphthaline = 14,000 cubic feet of gas, 42*s.*; 52 pounds of naphthaline, at 3*d.*, 13*s.*—Total, 55*s.*

Welsbach Incandescent.—One new large mantle 48-candle power, burning 3½ feet per hour = 7000 cubic feet of gas, 21*s.*; renewal of mantles, 3 at 2*s.* 6*d.*, 7*s.* 6*d.*; renewal of chimneys, 1*s.* 6*d.*—Total, 30*s.*

Petroleum.

Large Lamp.—One 48-candle Vulcun, burning 1 gallon in 28 hours = oil, at 7*d.* per gallon, 41*s.* 8*d.*; chimneys, wicks, &c., 2*s.* 4*d.*—Total, 44*s.*

Small Lamps.—Four 12-candle lamps, each burning 1 gallon in 84 hours = oil, 55*s.* 6*d.*; chimneys, &c., 2*s.* 6*d.*—Total, 58*s.*

Electric.

Incandescent.—Three 16-candle lamps, absorbing each 56 Watts = cost of current, at 8*d.* per Board of Trade unit (1000 Watt hours), 224*s.*; lamp renewals, 6 at 3*s.* 6*d.*, 21*s.*—Total, 245*s.*

Note.—The figures above apply to the use of the various illuminants under ordinary household conditions. Careful laboratory tests, of course, give better results.

COMPARATIVE ESTIMATE OF COST OF LIGHTING BY ELECTRICITY AND GAS.

ELECTRICITY.

Outlay on Plant.

	30 Lamps.	300 Lamps.
6-lbs. gas engine, 2 h. p. nominal, 4½ h. p. indicated	£85	£330
Dynamos—50 volts, 40 ampères	40	200
Lamps (16-candle), switches, &c.	20	100
Fitting	10	60
	£155	£600

Annual Expenditure.

Renewal of lamps, 30, at 3*s.* 6*d.*	£5	£50
Depreciation, 10 % on £130	13	55
Labour	20	30
Gas and oil for Engine, 3 h.p., 1500 hours, ¾ per h.p. per hour	14	120
Interest on plant, 4 % on £150	6	27
	£58	£282

(If using accumulators, add £100 to cost of plant.)

Gas.		
Gas consumption 288,000 cubic feet, at 2s. 6d. per 1000, using good ordinary burners, averaging 2½-candle power per cubic foot	£36	£360
Depreciation, repairs, interest on cost of fittings	4	40
	£40	£400

Note.—If electricity is supplied from public mains, at 8*d.* per Board of Trade unit, the annual cost, including renewal of lamps, will be £89 and £890.

Of course, what cannot be reckoned in above figures is the improved health when electric light is used; besides, the furniture, &c., does not get spoilt as when using gas.

Croydon Camera Club.—February 15, the President (Mr. H. Maclean, F.G.S.) in the chair.—Mr. A. Smith, junior, was elected a member. Mr. J. Wirth Brown gave a paper, which dealt with the newest modifications of his now well-known process for obtaining warm tones on bromide paper by means of the uranium toning bath. Prints and various solutions of precipitated uranium were shown, and a demonstration of the procedure necessary was given. Besides the usual brown and red tones, the lecturer explained how a green image could be obtained, suitable for sea pieces, also a blue one. The voting to decide the winner of the President's prize for the best print from a negative taken at a Club excursion in 1891 resulted in favour of Mr. Holland. The Annual Dinner of the members and friends will be held at the Greyhound Hotel, at eight o'clock on Thursday, March 17. An early application for tickets, price 4*s.*, should be made.

Putney Photographic Society.—February 17, Dr. W. J. Sheppard in the chair.—Undoubtedly the most elaborate, and one of the most practical, demonstrations before the Society was given by Messrs. Burton and Braham (representing the Autotype Company) *On Carbon Printing*. A short introduction and history of the process by Mr. Braham was followed by detailed explanations and the working of each stage in the process. Numerous prints, enlargements, opals, and transparencies, in all colours, were arranged about the room, and samples of the tissue supports, with the various actinometers, were handed round for inspection. That the process possesses the merits of cheapness, beauty and great simplicity, there can be no doubt. Its wider adoption by members of this Society is assured.

Brechin Photographic Association.—February 17, Mr. A. R. McLean Murray in the chair.—Mr. J. D. Ross (the Secretary) read a paper on *Shutters*. A large number of shutters were described, and about a dozen specimens shown, including snap-shot shutters with safety blind and time and instantaneous shutter with speed indicator, kindly sent down for exhibition by the Thornton-Pickard Manufacturing Company. These shutters were favourably commented on by the members, the safety blind being a particularly useful adjunct, especially in "magazine" cameras. Samples of the new Eastman rapid bromide paper were distributed.

Leeds Photographic Society.—February 15, Mr. S. A. Warburton (Vice-President) in the chair.—The subject for the evening was *Toning Bromide Prints*, upon which Mr. A. A. Pearson spoke as follows:—It is averred that after development, and before fixing, a bromide print will tone to almost the same range of colours as an albumenised one in the following bath:—Ammonium sulphocyanide, twelve grains; hypo, one grain; gold chloride, one grain; water, four ounces. I have failed to get anything but a little strengthening of the natural black, though gold is evidently deposited on the image, because it refuses to bleach in a solution of mercuric chloride. A second method is to bleach a finished print in a saturated solution of mercuric chloride, made by dissolving about ten grains to the ounce of warm water, and allowing it to cool, until the image nearly disappears; wash thoroughly for at least one hour, and immerse in a very weak solution of ammonia—not more than one drachm of "880" to a pint of water. The result is a rich, dark brown, which is unaltered by drying. If the ammonia is stronger, the colour disappears on drying. As this process intensifies the image, it is necessary to allow for it by a little over-exposure and under-development. A similar, but rather warmer, brown is obtained by substituting for the ammonia a ten per cent. solution of hypo. In this case the intermediate washing may be reduced to a mere rinsing under the tap, by immersing it after the rinsing in a five per cent. solution of potassium bromide for a few minutes, which is again washed out under the tap before immersing in the hypo. The tone is also improved by its use. We now come to the uranium method, by which any colour from dark brown, through sepia to Bartolozzi red, is easily obtained. The formula issued by the Eastman Company answers well, and will keep for a day or two in the dark:—Ferricyanide of potassium, nine grains; nitrate of uranium, eight grains; glacial acetic acid, five drachms; water, sixteen ounces. Drop the ferricyanide into a measure, pour a little water on, and run it off to dissolve away the coating of ferrocyanide which may have formed by the action of the light and air, add the nitrate, a few ounces of water, crush the crystals with a glass stirring rod, and, when thoroughly dissolved, add the acetic acid, and finally, the uranium nitrate. Immerse the finished print, which has been properly fixed and washed, and preferably dried. If dried, it is advisable to wet it again, by immersing in water. The brown tones appear in a few minutes, and finally the reds. Then wash well in running water for about twenty minutes, until the stain is cleared from the high lights. Too long washing will dissolve away the tone as well. The secret of success lies in thoroughly eliminating the hypo after fixing, the slightest trace causing a stain in the high lights which cannot be removed. If running water is not available, the prints may be floated, face downwards, for half an hour or more in a dish of water, which is changed several times. The above quantity will tone equally well a single quarter-plate, or a dozen 10 × 8 prints, the toning of the greater surface being only a question of time. It is recommended to tone by daylight. The acetic acid may be dispensed with if the solutions is to be used immediately, but if the water is hard, a little must be used to prevent the decomposing action of the lime, and any precipitate must be filtered out. Don't use rain water unless boiled and filtered. In this case, use three or four grains of each salt to the ounce, and after toning, clear, by immersing in a weak alum bath, or an ordinary hypo fixing bath, followed by a final washing. For brown tones, the print must be developed to about full density, but for reds the intensifying action is so great that it must be allowed for by using a rather weak and somewhat flat print. I find it best to use the ferrous oxalate developer—one drachm of iron to eight drachms of oxalate, and a single drop of bromide solution (Eastman's formula), and give a full exposure, so as to develop rapidly. Hydroquinone may be used; preferably the Ilford formula:—No. 1. Hydroquinone, one hundred and sixty grains; potassium bromide, thirty grains; sodium sulphite, two ounces; water, to twenty ounces. No. 2. Sodium hydrate, one hundred grains; water, twenty ounces. Use one part No. 1, one part No. 2, one part water. The exposure required will be about twice that for ferrous oxalate. Hydroquinone has a tendency to blister and soften the film, whereas ferrous oxalate hardens it. For blue and green tones put five or six drops of a saturated solution of ferric chloride (perchloride of iron) into a measure and add two ounces of water; pour this on to one of the washed red or red-brown prints in a dish; the half-tones will rapidly become bluish-green, and, if stopped by immersion in water before the shadows are fully changed, the resulting print will present a moonlight effect, with dark olive-brown shadows and blue-green half-tones, and just sufficient tinting of the whites to be natural. This tone is most effective in a transparency or an enamelled print, which should not be weak or flat to begin with. For pure Prussian blue, put three or four drops of hydrochloric acid into a measure, add two ounces of water, and pour over the print. In the meantime put three or four drops of the ferric chloride solution into the measure, and return the acidulated water to it; flood the print with the mixture, which will rapidly change it to the colour of a ferro-prussiate print. If this be well washed, and a very weak solution of ammonia (not more than two drops to the ounce) poured over, it will change to a purple blue, very like the bloom of the agapanthus, or African lily. A stronger solution will completely bleach it. In all cases, wash the print finally as directed. With regard to any slight stain in the high lights, it does not appear to be detrimental to the artistic effect of a picture, if the stain is not so deep as to materially shorten the scale of gradation.

Manchester Photographic Society.—February 11, Mr. Abel Heywood, jun. (President), in the chair.—A number of every-day matters photographic were introduced. The question of plate backing received attention from several of the members, who gave their methods and experiences. Mr. Chilton used burnt sienna, as sold at the colour shops, mixed with a weak solution of gum, laid on the back of the plate with a flat brush. Mr. Coote used a brown pigment in a similar way. Mr. Wood was in favour of black tissue paper stuck on with glycerine. This is easily removed, and he did not consider the glycerine left on the plate any detriment to the developer. Mr. Hughes employed a piece of black velvet pressed against the plate in his single backs. The opinions as to the benefits from backing plates were varied, as far as the speakers' experiences went. Under some conditions backing was of very little use, and a reliance on correct exposure, in the opinion of a few, was more important in obtaining good results. To dry plates treated with a moist pigment, a light-tight box or packing case, which had been previously well warmed before a fire, was recommended as the simplest and safest, the well-dried wood being sufficient to absorb the moisture given off. Mr. Edwards gave a demonstration of his method of working. He first explained his hand camera, which was the result of several seasons' experiences. It is for plates 3¼ × 3¼, a special feature being that the lens is fixed on the outside of the roller blind shutter and a little above the centre line of the plate. This gives the benefit of a raised front, which he had found to be most required. By placing the camera on its side, the horizon would be central on the plate, and by holding the camera upside down the advantage of a falling front was obtained. Mr. Edwards did not print direct from his small negatives, but by means of a very simple home-made apparatus printed enlargements on bromide paper. He very successfully demonstrated the ease with which these were obtained, though good results could only be obtained by proper timing of each negative and careful development. He used the albo-carbon gaslight in his lantern. This gives a fairly regular light, so that, once the correct exposure is obtained for each negative, any number of prints of a uniform quality can be made. In developing, ferrous oxalate was used; and, by the control given by the use of the acid bath and local application of developer with a brush, he considered it the best for general work. Mr. Edwards promised to show his method of putting in clouds to the developed prints, and other dodges in finishing up pictures, at the next meeting. Swinden and Harp's latest hand camera was shown and explained by Mr. Bennington. Several improvements have been made since the last appearance of this firm's apparatus was before the Society. A developing contest was arranged for. A number of variously exposed plates were to be distributed to the members, who were to develop them to the best of their ability, and bring the results to the next meeting.

Midland Camera Club.—February 19, Dr. Hall Edwards in the chair.—Mr. Belcher showed the "Cytos" electric dark-room lamp, a new introduction of Philip Harris & Co., worked by five cells; Frederick Iles, a method of his own of etching lantern slides; Professor Allen, two platinum prints, to illustrate charp versus fuzzy prints. The meeting then adjourned to the Examination Halls, where a good muster of ladies and gentlemen, friends of the members, were waiting for the lecture by the President on *Photography as an Art*. In the course of his lecture, the President showed slides by the following members:—Mrs. Welford, Roland White, S. G. Mason, and W. D. Welford; also by Mr. and Mrs. Francis Clarke, J. P. Gibson, Edgar G. Lee, Harold Baker, and G. W. Wilson & Co. The slides receiving most appreciation at the hands of the audience were decidedly those of Mrs. Clarke and Edgar G. Lee. A number of freaks and distortions were shown as, "what not to do."

Newcastle Photographic Association.—February 16, Mr. J. P. Gibson (Vice-President) in the chair.—The Secretary (Mr. Edgar G. Lee) read the report of the Council for 1891, which congratulated the members upon the continued prosperity of the Association, the membership having increased from 115 to 140 during the year. Outdoor meetings had been held at Bellingham, Fountains Abbey, Rothbury, and Barnard Castle, and had been unusually well attended. In the competition promoted by the Association, the

class devoted to lantern slides was of very high quality; but the class for prints, confined to amateur members of the Association, both in number and in quality, was much below what ought to be expected from an Association like theirs. The report was adopted. Mr. T. O. MAWSON read a paper *On Platinum Toning on Matt-surface Paper* [this will appear in a future number].

North Wales Photographic Society.—The want of an amateur photographic society has long been felt in North Wales, as, notwithstanding the fact that there are some 250 such Societies in Great Britain, only three of these are in Wales, and they are in the southern portion of the Principality. To meet this want a few of the leading local photographic lights met at the Llandudno News-rooms on the 18th inst., and, as a result, a Society has been formed under the title at heading. Two well-appointed, commodious dark rooms are already being fitted up with the latest, most approved appliances and fixtures. All the daily and weekly papers—of course, including the photographic—will be available to members; a billiard room, with two tables, adjoins the reading-room, and there is a well-stocked library. It was decided to admit visitors to membership during the time they are staying in the neighbourhood for a subscription of 1*s.* per week, the use of dark rooms for developing being charged for at the rate of 1*s.* per hour, which charge includes gas lamp, fixing bath, water, trays and measures, &c. For changing plates a charge of 3*d.* for ten minutes will be charged. This is expected to prove a great boon to visiting amateurs, who flock to the town in large numbers during the summer months. The Secretary will be glad to receive further names of members wishing to join, addressed to him at the Llandudno News-rooms, Mostyn-street, Llandudno. Meetings, first and third Thursday in each month; also, monthly lantern exhibitions, demonstrations, lectures, or *soirées*. A paper was read on the 19th inst., in the rooms of the Llandudno Debating Society, by Mr. W. A. Whiston, on *Amateur Photography*. The lecturer gave a very complete history of the birth and development of the "black art." This he followed by a practical demonstration, comprising, *inter alia*, the production of a negative by flashlight of the Chairman (Rev. J. Raymond). This was developed in view of the audience, fixed, dried with spirit, and a lantern slide printed, developed, fixed, dried in a very few minutes, and shown by the oxy-hydrogen lantern, ably manipulated by Mr. Hughes, of Rochester House. Several defective slides were then thrown on the screen, the lecturer pointing out the faults in each. One slide, made by the lecturer, was a most amusing instance of double printing. It was a large steam yacht, steaming up Lake Ogwen. Puzzle—How did the yacht get to this inland Welsh lake?

Tyneside Camera Club.—February 11, the President (Mr. J. F. McKie) in the chair.—A paper was given by Mr. W. BELL *On Chloride of Silver Emulsion Papers*. In the discussion Mr. ROTHWELL said he printed a piece of chloride of silver paper, and made a toning bath ten months ago, and toned the print last week; the whites of the print were slightly grey, but it toned splendidly; the print was not kept from the air, but in a dark place.

Correspondence.

DALLMEYER'S REFLECTING MIRROR.

To the EDITOR.

SIR,—I have just finished reading, in your last number, Mr. T. R. Dallmeyer's paper on *Reflections Combined with Refractions*. It concludes thus: "Another application that has struck me as useful for such class of reflecting mirrors, on account of the large angular aperture attainable, is in regard to use in naval work for scanning the horizon in dull weather. If such a mirror, a foot or more in diameter, were mounted in some manner, such as a ball and socket mounting from its centre, carrying an eyepiece on an arm, a rapid and powerful search might thus be made of the horizon." If by this Mr. Dallmeyer means the employment of the mirror he describes to throw a strong beam of light over the sea as a search-light, he has been anticipated in his suggested application several years ago, the mirror being a lenticular one, similar to that which he describes in his paper. Reflectors of this nature, that is, concavo-convex lenses, silvered on the convex surface, have long been before the public, and have been applied to the very purpose now suggested.

The credit of this application of the reflector belongs to Messrs. Mangin, Lemonnier, & Co., of Paris, who protected their invention by patent some years since. There are eight special claims in their patent, the two first being as follows:—"1. The construction of a reflector of silvered glass, with spherical surfaces having different curvatures, and in which the spherical aberration, due to reflection, is compensated by the spherical aberration due to the refraction. 2. The employment, substantially as described, of the said reflector in the construction of apparatus for projecting light." If, therefore, Mr. Dallmeyer has presented the reflector as a novelty, I hope he will not take it unkindly of me in pointing out its antiquity relative to every-day inventions.

Perhaps I may also be permitted to express my surprise at such veterans as Captain Abney and Mr. Traill Taylor, who, according to your report, were present when the paper was read, and both of whom must have known better, listening to the paper without saying a word indicating knowledge of the previous existence and application of the mirror, facts of which they must have been well aware.—I am, yours, &c.,

Devonport, February 16, 1892. COMMANDER.

[Our correspondent is too clever. Mr. Dallmeyer's paper consisted merely of a mathematical demonstration of means by which the spherical aberration of parallel rays from a large reflecting concave surface could be eliminated, and the exhibition of a reflector in which this was accomplished. His suggestion for the employment of such a mirror for naval purposes had not necessarily any connexion with its use as a search-light, and if "Commander" had grasped the subject more comprehensively he would have noted, what he quotes above, that an *eyepiece* forms an element in the suggestion, implying the formation of an image, a thing totally different from the scope of a search-light. We freely grant to the French firm named the credit of the application of this special form of mirror to the purpose claimed, but take exception to the validity of the first of their claims, viz., the construction of such a reflector; for in a work on the ophthalmoscope, by Dr. Adolf Zander, kindly brought under our notice by a friend, a translation (from the German) of which, by Dr. Brudenell Carter, was published by Hardwicke in 1864, we find a drawing of just such a reflector as that claimed by the French firm, whose patent only dates from 1880, thus being anticipated by sixteen years. There was nothing in the paper to call for other remarks from Captain Abney and Mr. Taylor than those made by them—viz., the former speaking of the advantages of a reflector for a certain class of investigations made by him, and the latter stating that the reflector made and exhibited by Mr. Dallmeyer exceeded in angular aperture anything he had ever previously seen.—ED.]

MR. COLES AND MR. HOWSON.

To the EDITOR.

SIR,—The remarks made by me at the meeting of the London and Provincial Photographic Association to which Mr. Howson takes exception were to this effect, that Mr. Howson claimed *absolute* permanency for gelatino-chloride prints, and quoted Professor Burton as an authority for such claims, but that I thought the Professor was too careful a writer to have committed himself to the statement that either gelatino-bromide or gelatino-chloride prints were *absolutely* permanent. (The reports vary slightly, but the above is what is evidently alluded to.) As Mr. Howson says last week, "This is a matter which can be easily verified;" but it is, I submit, for him to do it by quoting the Professor's words from his published writings.

I am, of course, responsible for mixing up the questions of the permanency of bromide and chloride prints, but it never occurred to me that any one would claim greater permanency for the latter than for the former. Although in the latter, when toned with gold, the image may consist partly of that metal, yet, as the toning process is usually carried out, the substitution of gold for silver is by no means complete, and, unless special precautions are taken to the contrary, the image must consist to a certain extent of silver.

It did therefore, and does still, appear to me that if bromide prints are found to be unstable under the unfavourable conditions to which photographs must frequently be subjected, it is somewhat premature to claim "absolute permanency" for gelatino-chloride prints.

I have no wish to injure any reputation which Mr. Howson may have gained for moderation, but it was precisely because his claims seemed the reverse of moderate that I ventured to call it in question.

I readily agree, after the admission that has been made, as to the way in which the Alpha prints used as illustrations to THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC were produced, that we cannot regard any faded copies as necessarily implying instability of the process. No one would rejoice more than myself to find eventually that we could look upon the new gelatino-chloride paper as thoroughly reliable under all conditions to which photographs have to be subjected. As, however, there are probably no prints by that process existing which Mr. Howson would admit as evidence if found in a faded condition, may I be allowed to make the following suggestion, which I think many of your readers would like to see carried out?

Let Mr. Howson arrange with the publishers of one of the photographic papers to issue a print on the new printing-out paper, bearing a statement to the following effect:—

"This print is on . . . . paper, the correct manipulation of which is guaranteed by . . . . Prints, by this process being *absolutely* permanent, may therefore be subjected to the same treatment as engravings or platinum prints, *i.e.*, may be hung on a damp wall, sent abroad to damp climates, exposed to the impure atmosphere of badly ventilated rooms in which gas is burnt, used as book illustrations in contact with ordinary printing paper, or mounted with ordinary paste on common cardboard without risk of fading."

Notwithstanding occasional differences of opinion, Mr. Howson's genial presence is always welcomed at the various photographic meetings, and it would enhance the value of the print if he would let it be a portrait of himself. He is a good subject for the camera, and no doubt many would like to have a portrait of him, which we must hope would prove to be permanent.—I am, yours, &c.,

WILLIAM COLES.

Watford, February 22, 1892.

P.S.—I have no wish to prolong the controversy; but, if continued, may I ask the favour of its being restricted to one paper, as I cannot undertake to write letters on the same subject to two or three different periodicals.

ROYAL COMMISSION FOR THE CHICAGO EXHIBITION, 1893.

PHOTOGRAPHIC DEPARTMENT.

To the EDITOR.

SIR,—I should be much obliged if you would kindly give publicity to the following facts relating to photographs, &c., at the Chicago Exhibition.

Photographic apparatus and photographs are classified under Group 151 (instruments of precision, experiment, research, and photography, photographs), which is included in the department of Liberal Arts.

Photo-mechanical prints and processes, photogravures, &c., are classed under Group 76 (photo-mechanical and other processes of illustrating), which is, like lithography and printing generally, included in the department of Machinery.

All the photographic exhibits, however, will be placed together in the portion of the Liberal Arts and Manufactures building allotted to the British Section.

Screens will be fitted up for the exhibition of photographs, photogravures, and other pictures produced by photographic methods.

For the space on these screens the charge will be 2*s.* 6*d.* per square foot, with a minimum charge of 2*l.*

Exhibitors desiring to erect their own screens or stands can do so. In that case they will be charged for the ground they occupy according to the same scale as other exhibitors, viz.:—

									s.	*d.*	
For spaces not exceeding 100 sq. ft.					...	...	...		5	0	per sq. ft.
,,	exceeding 100 sq. ft.		and not exceeding		200	sq. ft.			4	6	,,
,,	,,	200	,,	,,	,,	300	,,		4	0	,,
,,	,,	300	,,	,,	,,	500	,,		3	6	,,
,,	,,	500	,,	,,	,,	750	,,		3	0	,,
,,	,,	750	,,	and upwards		...	...		2	6	,,

The minimum charge will be 5*l.*

All goods intended for the Exhibition will be admitted duty free, but on anything sold the usual Customs duty will have to be paid.

The English railways have undertaken to carry goods for the exhibition at half rates, and several of the more important steamship companies have consented to convey them at the reduced rate of 11*s.* per ton. The American railways will charge their ordinary rates on goods to the Exhibition, but undertake to bring them back free.

The Exhibition will be opened on May 1, 1893, and closed on October 30, 1893.

Applications for space in the British Section must be made upon forms to be obtained from myself, at the Society of Arts, John-street, Adelphi, London, W.C., and I shall also be very pleased to supply any further information. The forms should be sent in, properly filled up, not later than February 29, 1892, and addressed to me as above. After the end of this month, applications can only be received subject to space being available.—I am, yours, &c., HENRY TRUEMAN WOOD, *Secretary*.

Society of Arts, John-street, Adelphi, London, W.C.,
February, 1892.

PHOTOGRAPHERS AND THE TRADE.

To the EDITOR.

SIR,—Allow me to thank you for your article on this subject, and, as a member of the N.A.P.P., to congratulate the executive on what it has achieved in inducing some of the trade houses to treat photographers a little better than they have hitherto done. I have no doubt that if, during the last eight or nine years, the manufacturers and trade houses had invariably accorded such terms to the profession as they had a right to, the severity of the depression which has afflicted professional photography would not have been felt so keenly as it has. It is notorious that amateurs and the general public have very frequently been allowed to buy as cheaply as, if not more cheaply than, the poor professional, and the consequence of this is that a great deal of work that should have passed through his hands has been diverted from them. In fact, the amateur and the public have been allowed to buy too cheaply.

In other fields of commerce the wholesale houses make a study of protecting the trade by not supplying their goods retail, and by this means they encourage the retailer, and are sure of his support, and consequently of the ultimate patronage of the public. To the system lately obtaining in the photographic trade I can only see one finish—namely, depression among the manufacturers and trade houses, arising out of the fact that the middlemen (*i.e.*, the dealer and the photographer) have been passed over in favour of the general public, whose support wants cultivation of a particular kind which the wholesale man is less able to exert than the photographer.—I am, yours, &c., A COUNTRY PHOTOGRAPHER.

Leeds, February 22, 1892.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—March 7, *History of Gelatino-bromide Photography*, by Mr. J. Burgess. Visitors invited.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—March 3, *A new Enlarging Lantern without Condensers*, by S. H. Fry. 10, *The Wet Collodion Process*, by W. E. Debenham. 17, Monthly Lantern Evening.

ON Saturday afternoon last the *employés* and friends of Messrs. Percy Lund & Co., to the number of over one hundred, held their annual social evening in the Temperance Hall, Bower-street. Tea was served at 4.30 p.m., and at six o'clock the entertainment was commenced with a few opening remarks from Mr. Percy Lund. The principal items of the programme were an action-song, "Merry Gleaners," in which twenty-four of the junior *employés* took part, and a performance by the Practical Professional Amateur White Minstrels. A number of songs, duets, recitations, and instrumental items were given, with games interspersed.

CHICAGO EXHIBITION.—We understand that the British railways have undertaken to carry goods for British exhibitors at the Chicago Exhibition, to and from the port of shipment, at half rates. The American railways will charge their usual rates to Chicago, but will bring back the goods free at the close of the Exhibition. Many of the principal steamship companies have reduced their rates considerably, and will take freight for the Exhibition at 11*s.* per ton. Many of them have also consented to adopt a reduced passenger tariff for exhibitors and their *employés*, certified as such under the authority of the Royal Commission.

THE Birmingham Photographic Society's exhibition of photographs by the members will be held in the Young Men's Christian Association Rooms, Needless-alley (electrically lighted), on April 5, 6, and 7, 1892, from ten a.m. until ten p.m. each day. Twenty-six silver medals, a silver cup, two hand cameras, and other valuable prizes (besides certificates), are offered for competition among members only. In connexion with the exhibition there will be an exhibition of apparatus, and lantern shows will be given each evening. The Hon. Secretaries are Messrs. J. T. Mousley, 26, Portland-road, Edgbaston, and A. E. Tucker, 26, Paradise-street, Birmingham.

A CAMERA CLUB FOR CHISWICK.—A meeting of a few of the amateur photographers of Chiswick was held at the residence of Mr. R. W. Watson, to consider the advisability of forming a Club for this district. The matter was fully debated, and a resolution to form such a Club was carried unanimously. A Committee was appointed, and a number of members enrolled. A room has been taken at No. 344, High-road, Chiswick, which will be open for the use of members every Monday evening from seven to ten. Mr. H. Harding Miller has been appointed Hon. Secretary, and will be pleased to see any inquirers at the rooms on Monday evenings. A meeting was held on the 22nd inst., Mr. R. W. Watson in the chair.—The subject of platinum and bromide printing was discussed. February 29, *Lenses*, by A. E. Steadman.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN AFFILIATION SCHEME.—At a meeting of delegates, February 15, 1892, Mr. W. Bedford (P. S. G. B.) in the chair, the rules of the affiliation, as approved by the Council, were adopted. It was agreed that the Lantern Slide Sub-committee should put the Indian and Colonial set in circulation, obtain other sets as gifts or loans, and formulate regulations. It was decided to await the report of the Committee appointed by the Photographic Society of Great Britain on the methylated spirit question before taking any steps in the matter. It was decided to ask the Council what funds were at the disposal of the Committee, and that a list of dark rooms, available for the use of the members of the affiliated societies, should be prepared. It was decided that summonses to meetings should be sent to delegates only; all other communications were to be addressed to the secretaries of the affiliated societies. It was also decided to form a collection of good and instructive work for circulation, and that steps should be taken to promote the interchange of papers between the societies forming the affiliation.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—In the St. George's Hall of the Champion Hotel, Aldersgate-street, on Thursday evening, February 18, the Annual Musical and Lantern Entertainment was given to a large assemblage, including many ladies. Mr. J. Traill Taylor presided, and, in welcoming the guests, remarked that the London and Provincial Association was recognised as the leading English technical photographic Society, the reports of its proceedings always being read with great interest. A deal of useful work was done by the Association, and the entertainment of that evening was a relaxation from those labours. A capital programme was then gone through, to the extreme pleasure of the visitors. Misses Edith Teape and Helen Anderson, and Messrs. F. Bull and W. A. Ellesten contributing songs, Misses Jessie Drage and Edith Teape pianoforte soli, Messrs. Ashley Cowan and A. S. Newman recitations, Mr. H. Ellesten mandoline and Mr. F. W. Parfitt violin soli. Displays of lantern slides, the lantern microscope, by Mr. T. R. Freshwater, and the lantern polariscope, by Mr. J. J. Briginshaw, lent an agreeable diversity to an entertainment which was most successful throughout.

RICHMOND CAMERA CLUB.—An Entertainment was given in the College Hall, Richmond, on Friday, the 19th inst., consisting of music and a display of lantern slides by members of this club. About 300 friends of members were present. Mr. F. P. Cembrano, the President, in a few introductory remarks, asked for a little indulgence as regards the lantern part of the performance, the club being a young one. He said, however, that, although the club was young, it was rapidly growing. The programme was so arranged that music and slides alternated, an arrangement which gave considerable satisfaction. The musical part of the programme consisted of glees, songs, recitations, party and piano solos, all being well rendered by friends of members. The lantern display was of a miscellaneous character, slides being shown by Messrs. Cembrano, Behan, Such, Hunter, Ardasser, Faulkner, Davis, Perry, Bickerton, Ramsey, Keysey, and Ennis. The slides by Mr. Cembrano of Salisbury Cathedral and Glastonbury Abbey, taken during the meeting of the Photographic Convention last year, attracted a good deal of attention; and Mr. C. H. Davis's slides of Venetian and Tyrolese scenery were much applauded. The lantern was kindly furnished and manipulated by Mr. Beard. The entertainment passed off without a hitch, and the members of the Richmond Camera Club have every reason to congratulate themselves on this—their first—performance.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

**** Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," *2, York-street, Covent Garden, London.*

R. T. MARSLAND.—Received.

J. F.—Either form of jet will answer.

IRIS.—Thanks. By all means let us hear from you.

BART ROUS; D. D.; and others.—Thanks; in our next.

E. W. MANDEN.—No such report has appeared in our pages.

C. J. KIRK.—See answer to "E. P. C.," in the JOURNAL of February 12.

ARGUS.—From what we know at present we would give preference to No. 2.

H. J. BRISTOWE-DAVIS.—The picture is an admirable example of this class of work.

W. A. T.—1. There is a chapter on "Enamelling Prints" in the current ALMANAC. 2. Yes.

W. BARNETT.—The use of cyanine is not patented, neither is that of chlorophyll. The results are interesting.

CHARLES SWAIN.—Thanks. Such an arrangement as you sketch has been in use for a number of years.

ECONOMY.—Modern developers do not hold silver in solution, hence the "reduction" you speak of would be futile.

HERMANN ERNST.—Dr. Kopp exposed the paper in the camera, by which means he is said to have obtained positives in colours.

W. A. LEGG.—For the proceedings of the Physical Society, apply to the Secretaries of that body at the Royal College of Science, South Kensington.

AMATEUR.—With stops of equal size, both lenses named will work with equal rapidity. Your orthographic lens will not be suited for architecture, as it will give pincushion distortion.

YORKS.—Most large dealers in photographic materials supply glasses with bevelled edges for the so-called "opalines," also ground opal glass for "porcelains." Write to some of those whose address you will find in our advertisement columns.

R. A.—Quite right; you can patent anything you like, and the patent will be sealed in due course if no one opposes. The patent being sealed is, however, no protection to the owner of it from being proceeded against for infringement of another patent for the same thing.

T. PAGE.—If you get "an excellent emulsion that yields perfectly clear shadows, but is rather too slow," its rapidity may be increased by extending the time of "cooking." As you are giving an hour and a half, try two hours or more, until you obtain the necessary sensibility.

M. STARKE.—The fault in the two negatives forwarded is that of over-exposure. As a beginner, you have overlooked the fact that the quality of the light has improved greatly during the past few weeks. It will continue to do so rapidly during the next month or two, so be on the alert.

A. F. M. POWELL.—The idea is good. The movement will work quite well. It was employed more or less extensively in or about 1854. It has not been patented. If you turn to our ALMANAC for 1874, you will see the subject dealt with on page 29. It is rather more fully dealt with on page 56 of our 1887 ALMANAC.

E. S. J. says he has some bromide paper that he has had by him several years, and it works all right. He asks if enlargements made on it now will be likely to prove as permanent as those on freshly made paper?—If the results are good, we see no reason to doubt their stability as against those on newly prepared paper.

C. DE PASS.—A cast from a Woodbury gelatine relief can be made in the ordinary "fusible metal," but not from a swelled gelatine relief, as the heat of the metal would cause the raised and more soluble portions of the gelatine to melt. A mould can, however, be made in plaster of Paris. A plaster cast from a soft gelatine relief will not be so sharp and crisp as one in fusible metal from a dry Woodbury one.

D. W.—1. One ounce of hyposulphite of soda to the pint of water is quite insufficient to fix prints, even if the time be prolonged to twenty minutes. Better risk blistering than have fugitive prints. 2. One grain of chloride of gold ought to tone a full-size sheet of paper, or its equivalent in prints, to a rich tone. Of course, the deeper the prints are toned, the more gold will necessarily be consumed in the operation. If only red-browns are wanted, less gold will be required.

SCOTSMAN writes that he has heard it stated that celluloid prints do not keep so well as plates, that is, after a time only foggy negatives can be obtained. He asks if this is correct?—Different opinions have been expressed on the subject. Theoretically, glass is inert on the gelatino-bromide. That can scarcely be said of a substance containing camphor and other volatile compounds. The emulsion may also be a factor in each case. On glass even some emulsions prove more stable than others.

WANDSWORTH asks, Can the rector of a village church prevent any one who has not obtained his permission from taking a photograph of it from the roadway? He adds that a friend of his was, some time back, "ordered off" by the sexton, on the ground that the rector had given a local photographer the exclusive right of photographing the building.—The rector has no power to prevent any one from taking photographs of the church, and we should not have surmised that any minister would be so foolish as to usurp it.

C. F. R.—1. Both Messrs. B. J. Edwards & Co. and Mr. J. Cadett would, we believe, supply you with a coating machine. 2. *Photography with Emulsions*, by Captain Abney (Piper & Carter).

SIWASH writes: "1. Can I copyright a portrait of a gentleman taken by me gratis without a letter of assignment? 2. Or a portrait, the negative of which was taken in my studio on the sitter's plate and then presented to me?"—In reply: 1. The copyright in a photograph is vested in the author of it. 2. The mere fact that a photograph was taken in a certain studio does not confer a copyright in it to the owner of the building, nor does the presentation to him of the picture itself, for the reason given in reply to the first query.

S. W. sends us a cabinet photograph, half of which has been stuck on to a mount, while the other portion is left free. That part which is attached to the mount shows unmistakable signs of fading, whilst the other does not. Our correspondent asks if this is not conclusive evidence that the cards are the cause of the fading, and if the dealer who supplied them is not liable for damages?—The evidence is by no means conclusive, inasmuch as the material used for mounting may be the cause of deterioration. Before taking proceedings to recover damages, our correspondent must make sure that he can prove that the fading is caused by the cards, and the test applied certainly does not do that.

H. HOLMES write as follows: "Most modern songs now bear the following on the titlepage, This song 'may be sung in public without fee or licence.' With this intimation, should I be doing wrong in making lantern slides of the music and showing them on the screen for the audience to sing from?"—All the modern music we have seen bearing the above intimation also bears something to the following effect: The sole and exclusive right of making manuscript or other copies of this work is vested in the owner of the copyright, and any other persons making such copies, without permission, render themselves liable to heavy penalties or damages. "Other copies" would certainly include photographic ones, whether for the lantern or on paper.

F. S. writes: "1. Can you kindly inform me if it is a usual thing for makers to put up seven drachms in the so-called one-ounce bottles of pyrogallic acid? Of late I have noticed that negatives having had plenty of exposure fail to give the required density without a further addition of pyro. On searching the formula of another maker, they say, 'Pyro, one ounce; but if the ordinary one-ounce bottles are used, add an additional drachm.' On following this advice, I found it answer my purpose. 2. In another formula, where carbonate of soda is used, the mention of (not bicarbonate) is made. Will you be kind enough to inform me of the difference, if any, between them? for on purchasing some at a chemist's, I informed him I wanted carbonate (not bicarbonate), which caused him not a little amusement. On mixing my developer, I failed to get the least appearance of my subject. Having tried two or three times, I purchased some at another chemist's, and, lastly, at a grocer's, all to the same effect. On writing to the makers of the plates, explaining my failure, they kindly offered to develop a plate for me, and, on the return of same, I found they had produced a negative with good printing qualities, informing me the only thing they could suggest was the impurities of the carbonate of soda. If you can kindly give me any information through your 'Answers to Correspondents,' you will oblige."—1. An ounce bottle of pyrogallic acid should contain 437½ grains of the acid, which is, roughly, three-quarters of a drachm short of the old apothecary's ounce of eight drachms, of sixty each, to the ounce. If eight drachms, or 480 grains, of pyro are required, the necessary addition must be made to the ordinary avoirdupois ounce-bottle. 2. The difference between the carbonate and bicarbonate has frequently been dealt with in our columns. The former is rarely kept by dispensing chemists, but it may be obtained from all dealers in photographic chemicals or from any operative chemist.

PHOTOGRAPHIC CLUB.—March 2, *Halation* and *Public Exhibitions*, by F. P. Cembrano, jun. 9, *The Oxyhydrogen Microscope*, by Mr. T. E. Freshwater, and *The New Incandescent Light*.

MESSRS. TAYLOR, TAYLOR, & HOBSON offer twelve and six guineas respectively for the two best negatives taken with their photographic lenses. The conditions of competition may be obtained from Slate-street Works, Leicester.

LIMELIGHT ENTERTAINMENT.—On the 15th inst. Mr. George Mason, of Glasgow, delivered his popular lecture, *Jack and I in Norway*, in the Patrick Free High Church. Sir Andrew Maclean presided. A good audience was present, and a cordial vote of thanks was awarded to the lecturer.

THE Ashton-under-Lyne Photographic Society held a very successful exhibition last week. The Society is only a year old, and numbers 190 members. In addition to the members, such men as W. L. Howe, J. Crooke (Edinburgh), W. W. Winter, W. D. Welford, R. Keene, G. W. Wilson & Co., Horsley Hinton, Rev. H. J. Palmer were represented on the walls, and there were lantern lectures by Paul Large, G. E. Thompson, and others. Want of space precludes us from entering into details of the exhibits, but we cordially congratulate the young Society on its success.

JOURNAL OF PHOTOGRAPHY.

No. 1661. Vol. XXXIX.—MARCH 4, 1892.

SLUM LENSES.

And why should there not be slum lenses as well as those for portraits, landscapes, or architecture?

A 'slum,' from our special point of view at present, may be considered as a narrow, darkly lighted court, with numerous squalid women and children grouped about the doors, especially during fine weather. Owing to the high surroundings and narrowness, the light which falls upon such groups is poor and attenuated, and hence, to obtain instantaneous photographs of them, a more than usually quick-acting lens is necessary.

For some time we employed for this purpose a small quick-acting Petzval portrait combination, having a rather round field; that is, one by which the oblique rays were brought to a focus on a plane nearer to the lens than the central rays. It is obvious that when, in naval phraseology, the court was raked by the camera, the sides of the subject were much nearer than the centre, and, according to the laws of conjugate foci, they would be brought to a focus on a plane approximating to that of the centre. But, as lenses of this class do not embrace an angle sufficiently large to give proper effect to this principle, we have concluded that every object is attained by the employment of one corrected to give a flat field. And, whereas a lens with a round field cannot be efficiently used for ordinary outdoor purposes, one with a flat field can. The balance of advantages is, therefore, to be found in the latter.

After a trial of several of the portrait class specified, we cannot find one in which a diaphragm can be inserted without a more or less pronounced flare spot resulting. We are now referring to outdoor, not studio, photography, and therefore it is important that for this purpose the portrait lens be employed with its full aperture, which, it need scarcely be said, is inimical to penetration, or, as it is popularly termed, "depth of focus." It is not considered necessary at present to give the optical reasons for the production of a flare spot when a stop is employed; it is enough to know that it is so. When a lens of this class is employed for the special purpose now before us, it should, as we have hinted, be one of sufficiently long focus to ensure its covering the plate to the margins with a degree of sharpness such as will not provoke comparisons between the margin and the centre; and this necessitates its being of more bulky dimensions than is sometimes desirable, and also precludes the possibility of getting near objects in, unless these are so focussed as to render the other portions subordinate to them.

The slum lens should partake somewhat of the character of the portrait combination in being able to define well with full aperture a narrow angle of included view in a weak light; but, to render it generally useful, it should, like the lenses of the rapid rectilinear type, be also capable of being employed with a small diaphragm without giving a central flare spot. This, we know, a portrait combination would do provided it were so shielded as to prevent the sky from having access to it, a condition almost impossible to be realised. Pending the advent of a lens which shall fulfil both conditions, we can only suggest for slum purposes the employment of one of the rapid cemented type.

This is a field of research which, when the season advances, will richly repay those who enter it. The picturesqueness of the groups there to be found is often such as to cause a slum photographer to produce pictures even when the pictorial or artistic instinct is almost wanting in the camerist.

DEVELOPMENT "THEORIES."

Although avowedly designed to submit for the consideration of his auditors the various hypotheses which have been made on the subject of the theory of development, the admirable paper by Mr. Adolphe M. Levy, which was recently read before the Photographic Club, and which will be found in another part of the Journal, nevertheless concerns itself in a distinctly practical manner with the applied branch of the subject, and within a brief space reveals its whole philosophy with such clearness and succinctness that, be the reader concerned with either its theory or its practice, or both, it would be difficult for him to rise up from a perusal of the paper without a feeling of intelligent satisfaction and, perhaps, profit. The sections of the paper dealing with normal exposure, under-exposure, and over-exposure respectively, concise as they are, would, in regard to accuracy and luminosity, be difficult to excel. For the beginner and the student their expository merits are as considerable as those of any previous contribution to the literature of the subject, which is saying much.

Mr. Levy discounts the value of discussing the "theory" of development by aptly observing that we know little or nothing about the nature of the latent image, which forms the basis of development. To that knowledge, slight though it is, he attempts no addition in the paper before us, nor can we gather that he himself favours any particular "theory" or "explanation" of the change induced by light on a gelatinous film of silver haloid. While fully appreciating this reserve in the first respect, we think that his paper would have gained in interest if, as a chemist of experience and competency, he had told us which of those "theories" (we use the term advisedly) struck him as being the most feasible, and therefore the one most worthy of attempted substantiation; for, until among experimentalists there is a commonly agreed basis upon which the rails of investigation and research may be laid down, it will be futile to look for either accepted proof or disproof of any one particular "theory" of the latent image.

But Mr. Levy possibly suggests the source of a clue to the mystery which has so long baffled photo-chemical investigators by premising that to his knowledge chemical action has never been said to take place between the silver compound and its vehicle during emulsification. Two facts, however, point to the assumption that such an action is tolerably probable—the first being that a film of pure bromide of silver, unenclosed by any vehicle, is far less sensitive to light than when incorporated with gelatine; and the second, that gelatine acts as a sensitiser, *i.e.*, an absorbent of liberated halogen at the moment of exposure. For aught that we know to the contrary, some true chemical reaction between gelatine and the silver haloid may take place during emulsification, the proof of which may conceivably be deduced from the circumstance that the mixture, when exposed to light, undergoes what is practically decomposition. Gelatine and pure silver bromide simply incorporated, that is, without emulsification, produce a mixture which, we believe, is far less sensitive to light than the emulsified product. If it is only a physical change which takes place in emulsification, it is hard to account for the fact that the developed photographic impression cannot be entirely removed from a gelatine plate, though to all intents and purposes every particle of the silver image is dissolved out. We suggest, as a probability, that the halogen-absorbing properties of gelatine are due to a chemical action which is set up between it and the silver haloid during emulsification, and that the precise nature of that action must be ascertained before the composition of the latent image can be known.

In glancing at the oxybromide theory of the latent image, Mr. Levy seems to be unaware that that theory, far from being recently introduced, was advanced many years ago by the late Thomas Sutton. This, however, is a fact of which modern writers may pardonably be ignorant. But it is greatly in its favour that the oxybromide theory should, *longo intervallo*, have been independently put forth by, we believe, Dr. Hopkinson, who in all probability was not aware of Sutton's writings. In this connexion we must confess to a feeling of disappointment, that Mr. Levy has quite neglected to notice the beautiful experiments of Mr. Carey Lea, endeavouring, and not, we think, altogether unsuccessfully, to establish the identity between what he termed the photo-salts formed by light on films of haloids in gelatine, and similar bodies prepared by chemical means. Certainly, in any disquisition upon of examination of the theory of the latent image, the omission of Mr. Carey Lea's work is a serious flaw; as to our thinking, the mass of evidence which he adduced in favour of his claim to have identified the reduction products of exposure on the silver salts, is greater and more weighty than that which has been urged on behalf of the oxychloride and subchloride theories.

The discovery of the nature of the latent image would, we have no doubt, be of more interest to experimentalists than to practical photographers, although it would be extremely rash to prophesy that the latter class would not ultimately derive direct benefit therefrom, as possibly that knowledge might enable us so to employ our reagents as to be able to develop all light impressions, however brief. At present our very ignorance of the nature of the reduction product probably operates as a barrier to the arrival of that consummation, although, from the number, variety, and range of power of the new reducing agents constantly being introduced, we are justified in believing that in the immediate future some appreciable diminution of exposures may be universally permissible.

We have inferred above that Mr. Levy's paper, in parts, is or much value from the point of view of those practically concerned in the art of development; but it also appeals with equal force to the student of theory, for whom it points a moral as obvious as it is useful. This is to preserve, on the much-vexed question of the composition of the latent image, a condition of open-mindedness and freedom from prejudice. In chemical science old theories have constantly to be rejected for new ones, and the study of the fascinating problem under notice is best approached in the mental constitution pointed at, which, however, so far as photo-chemistry is concerned, is at present, we are bound to observe, rather the exception than the rule.

COLOURED PHOTOGRAPHS.

Since our articles on this subject have appeared an important contribution to the question of the fading of pigments has been made in a paper read before the Chemical Society by Professor Hartley, F.R.S., on the acid action of drawing-paper of different makes, and which we shall shortly reproduce. It is only necessary here to briefly summarise the results of his investigations, which are to the effect that almost all hand-made drawing-papers of the highest quality gave acid reactions when suitably tested. They were not acid to ordinary litmus; but, when azolitmus was laid on with a sable brush like a water-colour wash, "such washes turned red upon the paper." Further, he found that the acid had such hold upon the fabric that many hours' washing failed to remove it entirely. It is obvious, therefore, that such paper would add another to what may be termed photographic dangers in the substratum of the drawing. It would, therefore, seem desirable that all photographs intended to be painted upon should, in their production, have a final wash of ammonia to neutralise any original acid or any absorbed during the chemical operations, and possibly held stubbornly by the fibres. This retention of acid is a most important consideration, and, if proved to take place with the acids employed in various paper processes, a factor that must be dealt with.

Leaving that point to be dealt with as each sees fit, it will naturally be looked for that we make some pronouncement upon the relative advisability of the general employment of body-colour or transparent, but it is impossible. To begin with, an artist insensibly leans to a certain style according to his surroundings and the school he attaches himself to. As to the relative permanency, there is no decisive evidence one way or the other. There is before us, as we write, a ten-by-eight silver print painted in water colour about thirty-five years ago. The background has been painted in transparent colour, and photograph and pigment alike have altered. The face, beautifully painted in body colour, has given way very little indeed, so little that, if the surroundings could be repainted, few would observe anything wrong. Here, body colour has stood and actually protected the photograph. On the other hand, we have lately seen carbon prints finished in opaque colour in which the carnations are gone almost entirely through the pictures, and but a dozen years old. Side by side with one of these we recently saw, at a professional photographer's, a picture practically finished in transparent colour, the same age, and perfectly fresh. But it is well known that simple water colours fade, and to such an extent that a Royal Commission was appointed to examine and report upon the subject.

But there is still to consider another method—that of finishing in pastel; and, as this style, especially since the

exhibition devoted to drawings done by it, has become of late very popular, it is evident that, if adapted to photography, and advantageous in other ways, its use should be popularised. It has every advantage; it is considered a method more nearly approaching the permanency of oil-painting than any; it covers well, beautiful effects are obtainable by it, and, if well done, the pictures are most effective. The colour, being carried by a body of inert powder, is not brought into close contact with the photograph, and so much of it is, in comparison, employed, that a slight amount of fading would be imperceptible.

Dealing, now, with the actual pigments employed, the course of our investigations has shown us that, owing, perhaps, to the need of a powerful colour in mixture to cover the dead opacity of the darks in a photograph, the colour crimson lake has been employed in a way no one would ever think of doing in ordinary water-colour work. Even for special touches in high-class work it is employed. Thus, in a popular manual upon painting photographs, we read: "For the darker touches and deeper shadows about the eyes and under the eyebrows, a little crimson lake or Indian red, or both . . . . . the lower lip with vermilion and lake or madder carmine." Now, we have to say that crimson lake is so utterly fugitive a colour that its use is highly improper in any flesh painting whatever; nor, indeed, would we recommend it either for drapery or adjuncts; it is sure to fade eventually. Recently some permanent red colours analogous to crimson lake, but more powerful, and therefore difficult to introduce, have been introduced. They are made from alizarine, and, we should consider, may safely be trusted where they can be used. For reds of the greatest stability in water colour, we have, as reds, Indian, Venetian, and light reds, and red ochre, vermilion being uncertain, and the invaluable madder colours, rose red, purple, and carmine, being less permanent. Ordinary carmine should be classed with crimson lake and banished entirely; scarlet lake also, which is only crimson lake and vermilion.

Among safe yellows may be included yellow ochre, raw sienna, orange cadmium. Pale cadmium is of doubtful permanency, and true Naples yellow should never be used. It is a seductive colour to employ, but most treacherous; it is certain to discolour, and at no distant time after being laid on. Chromes should not be used, they also discolour, and are dangerous to use without proper knowledge as to what can be safely mixed with them. For blues, ultramarine, artificial ultramarine cobalt, and cæruleum are available. Prussian blue is doubtful, and, unfortunately, indigo still more so. Most of the browns of the colourman are safe, madder brown and Vandyke brown being among the doubtfuls, and bituminous Vandyke brown quite unsafe. Ivory-black, charcoal-black, lamp-black, graphite, and Indian ink give a wide range for the production of greys, browns, and greens, and Chinese white is all that is needed for whites. Here is a tolerably complete list for any artist, and we may say, in conclusion, that, if no other result follow these articles than the banishment of crimson lake, carmine, and Naples yellow, they will not have been written in vain.

Medals.—Those members of the Birmingham Photographic Society who exhibit at their exhibition next month can scarcely escape honours. Twenty-six silver medals, a silver cup, two hand cameras, and *other valuable prizes*, as well as an unlimited number of certificates, are offered! The Birmingham Society is comparatively a small one, hence there is a possibility that every exhibitor may be a prize winner. Except to pot hunters, of what value can medals be that are obtained under such conditions?

Dissolution of a Society.—At a meeting of the Brighton Photographic Society on February 23, a resolution dissolving the Society was carried. It appears that, in addition to having a considerable balance on the wrong side, but little interest was taken by the members in the Society's welfare. We are informed that this dissolution is the outcome of negotiations which have taken place with the Brighton Natural History Society, of which the members of the late Brighton Photographic Society will in future be a photographic section.

Imperfect Marginal Definition.—Portability in apparatus now seems to be the order of the day, often to the derogation of the work. Particularly is this the case with many hand cameras. With the view to reducing the bulk, short-focus lenses that will not cover the size plate used are pressed into service. Consequently, when the image is enlarged, or, as a lantern slide, is projected on the screen, the want of definition at the margins becomes painfully manifest; whereas, had a lens of an inch or two longer focus been employed, this imperfection would have been obviated.

The Proposed Photographic Institute.—The *Daily Chronicle*, of Monday, contained a leader on this subject, in which it extended most gratifying support to the proposition. Our contemporary says that it was in response to the appeal of certain distinguished men of science that it gave prominence to the appeal. Be that as it may, our readers will find the views we set forth in our leader of February 19 reflected in the *Chronicle* article with a degree of fidelity little short of remarkable. Both the Photographic Society of Great Britain and photographers generally are to be congratulated on having obtained outside advocacy for the establishment of a Photographic Institute from our energetic daily contemporary.

Electric Light for Photographers.—The Pilsen Electric Company recently gave a demonstration of an electric lamp for photographic purposes, which, we understand, is already being successfully employed by several London and provincial photographers. The lamp, for which special carbons have to be provided, is fitted to a large concave radiator, which is swung on a lever that is actuated by a ball-and-socket arrangement. This allows of the system being placed at any desired angle, and consequently complete control is obtained over the lighting. The Pilsen lamp, we believe, can be worked by utilising the power now being supplied by the electric lighting companies along the principal thoroughfares of large towns; but, whether this or separate power be employed, the initial cost of an installation would be relatively small.

The Albumen Process.—Is the reputation of the albumen process for lantern transparencies in jeopardy? It would almost appear like it. Hitherto this process has generally been considered the very best of all for this class of work. Indeed, to pronounce a slide nearly as good as one by the albumen process was considered about the highest compliment that could be paid it. However, the recent competition at the Lantern Society has put another face upon the subject, for the best slide of each set was on collodio-bromide, by Mr. Ackland, while gelatine came second. Albumen figured low down in the list, being sixth, fifth, and fourth respectively; while, in two sets, collodio-albumen was last, and in the other only fourth. Even wet collodion made a better record. It might be said that the different processes were not well represented in their workers, but on this occasion, at least, this would not hold good. The albumen slides were by the firm of Levy, of Paris, and the collodio-albumen ones by Mr. Ackland, who may be looked upon as the former champion of the process.

Fading.—Attention is just now being given to the subject of the stability, or otherwise, of photographic prints by certain processes. In consideration of this matter it is desirable to separate the process itself from the material upon which it is worked. Paper, so far as colour is concerned, is well known to be anything but permanent. If it be exposed to light—a portion being protected for comparison—

in nine cases out of ten it will become discoloured, sometimes even in a few days. The discolouration is sometimes due to the material of which the paper is composed, and frequently to the colouring matter added to give it a fictitious appearance. Therefore the shortcomings of the paper should not be charged to the process. We were recently shown some photo-mechanical prints that had been exposed in a shop window for two or three weeks, which had become quite yellow in the lights owing to the change in the paper. In ordinary silver printing only the *Sare* and *Rives* paper are used, and both of these may be considered stable. But in other processes less high-class papers are generally employed.

Photographers' Benevolent Association.—At the annual meeting on Friday last the following officers were elected for the ensuing year:—President, Mr. J. Traill Taylor; Trustees, Captain W. de W. Abney, C.B., F.R.S., &c., and Mr. W. S. Bird; Treasurer, Mr. John Spiller, F.I.C., F.C.S.; Committee, Messrs. H. D. Atkinson, F. H. Berry, W. Bedford (Chairman), R. P. Drage, T. E. Freshwater, G. T. Harris, T. C. Hepworth, F.C.S., A. Mackie, E. W. Parfitt, J. S. Rolph, H. Snowden Ward, H. R. Hume, and F. W. Hindley; Honorary Secretaries, Messrs. H. J. Beasley and W. J. Tabrum (55, Chancery-lane, W.C.); Honorary Local Secretaries, Messrs. H. J. Walker (8, Broad-street, Bath), R. Keene (All Saints', Derby), J. Davie (186, Sauchiehall-street, Glasgow), J. B. Payne (Mosley-street, Newcastle), B. Howie (85, St. Giles'-street, Norwich), J. E. L. Brokenshire (48, Hotham-place, Millbridge, Devonport, Plymouth), T. S. Hicks (141, Cemetery-road, Sheffield), and J. Pyefinch (Mardol Head, Shrewsbury). The report and balance-sheet (to which we have already made reference) were adopted.

Profitable Overtime.—Our contemporary, *Trade, Finance, and Recreation*, in a series of articles on "Roads to Easy Fortune," has exposed a number of advertising frauds. A few weeks back it enlightened its readers on the pastel portrait business. Last week it dealt with another advertisement having reference to photography. "150*l.* given to any one finding our home employment not genuine. 25*s.* weekly easily earned at home, evenings, either sex, old or young, everywhere; for materials to commence work, send 1*s.*, —— & Co." Now, as some of our readers may possibly like to earn another five-and-twenty shillings a week by a little evening work, we shall tell them how it is to be done according to the shilling's worth supplied to our contemporary. If they do not take advantage of it, they may, at least, be amused. The articles supplied were a piece of common glass, about two inches square, an unmounted photograph, one inch by one and a half, of a lady, with very little on in the way of clothes; half an ounce of starch, and instructions for mixing it and mounting the picture on the piece of glass. The circular states that, when perfect, you can earn from twenty-one to thirty shillings a week without hindrance to any occupation you might have during the day. Sixpence per dozen is said to be paid for *cartes*, and ninepence for cabinets. Hence, one has only to mount a hundred of the former each evening to earn the promised twenty-five shillings.—*Eureka!*

Second-hand Apparatus.—The season is now approaching when photographers, professional and amateur alike, will be setting their apparatus in order—disposing of some with a view to replacing it with other of larger dimensions, or, maybe, of more modern construction, while others will be on the look-out for second-hand apparatus, in order to save a portion of what would be necessary to purchase new. Now a novice, seeing the latter, often makes a bad bargain, and finds, to his cost, that the lowest-priced articles are not always the cheapest in the end. Often apparatus is purchased on the strength of the reputation of the maker, and, frequently, quite regardless of the usage it has received since it left his hands—perhaps many years since. With regard to cameras and the like, the condition may generally be judged by a careful examination; but this is not always the case with lenses. It is often assumed that lenses, so long as the glasses are intact, do not deteriorate with age. This may be the case provided the instruments are not in constant use. If they are, however, the case may be different, and the difference will be dependent upon the usage they have received. If a lens happens to be dropped and no glasses are broken, no harm is supposed to be done; but the bruising of the mount may have caused sufficient jamming to alter the original figure of the lenses. Furthermore, careless wiping of the glasses, often done with the focussing cloth, tends to destroy the high polish of the glass upon which brilliancy of the image so much depends. It will be remembered that a few months back we directed attention to the subject of a small film of dust on the surfaces of the lens of a detective camera preventing brilliant negatives being obtained. Imperfect polish on the surfaces of a lens is just analogous to a film of dust, and has the same effect on the negative. These remarks are brought about by the recent examination of an old portrait lens by one of our first opticians. By careless usage the mount had become dented, and thereby strain put upon the glasses, the surfaces of which, by constant wiping, were rendered dull and grey. The consequence of this is that a lens, which was once an excellent instrument, is reduced in quality to that of one of second or third-rate foreign make.

RATIO OF GRADATION.—I.

The discussion that has been going on for some weeks past on the subject of Messrs. Hurter & Driffield's experiments and their deductions therefrom has a peculiar interest for me, as some years ago I attempted an investigation in much the same direction, but was compelled to reliquish it owing to the magnitude of the task. The conclusions at which these gentlemen arrive are so subversive of some of the pet beliefs of photographers, and so apparently contrary to the daily working experience of hundreds, nay, thousands, that the question may well be further ventilated.

Before examining closely into the facts, it is, however, desirable to clear the ground of one or two obstructions in the shape of matters that may give rise to misunderstanding. In the first place, with regard to the formulæ and method of development, I have not been able to obtain the full text of Messrs. Hurter & Driffield's communications, and am therefore confined to what information I have been able to gain from some of your correspondents. But, as far as I can see, a "normal" developer has been employed, with variations of a not very pronounced character, and the action has been continued to the utmost, or, in other words, the most has been "got out" of each plate. The exposures, too, I take it, have been also of the "normal" character, that is to say, such as would give a properly graded image with any of the usual developing formulæ.

Secondly, there is the difference in meaning of the word density as used by Messrs. Hurter & Driffield, and as understood generally by photographers. In the first instance, it is applied to the quantity of silver deposited upon a given area of the plate; in the second, to the degree of opacity or printing value of the different gradations. At first sight the distinction is not very clear, for it would be supposed that opacity and density of deposit meant one and the same thing. As I take it, Messrs. Hurter & Driffield mean to say that such is not the case, or that opacity does not increase in the same rate of progression as the density of the silver deposit.

With regard to this last point, I think there cannot be two opinions as to the correctness of their view. If it were otherwise, to use an *ad absurdum* argument, it would be possible, *in time*, to produce a photographic impression through any obstruction, however thick—a brick wall or an armour plate, for instance. But we need not go to such extremes, but simply study any simple actinometer scale, made by building up increasing numbers of layers of tissue paper or similar material. If the opacity varied directly with the thickness of the obstruction layer—the density of Hurter & Driffield—then the values of the successive gradations would bear a regular relation to one another; it might be 1 : 2 : 3 : 4, &c., 1 : 2 : 4 : 8, or 1 : 3 : 9 : 27, &c.—at any rate, it would be regular. But is this so? In my own experience, certainly not; I have never yet found any form of actinometer screen that followed such a rule. The Warnerke scale is supposed to do so; but, even in the best examples of it, it is very doubtful whether the gradation is even approximately accurate.

That increasing the density of the deposit—in the sense of Hurter & Driffield—increases the opacity or power of stopping the light, "printing value"—call it what you will—in a greater relative degree

is easily demonstrated. Take two extremely thin transparencies from the same negative and superpose them, then view the combined picture by transmitted light, and the apparent increase of density (in the sense of opacity) is far greater than an examination of the separate images would lead one to suppose. Again, to take a very familiar instance, how very faint—to the eye—appear the strokes of the retoucher's pencil on the negative, yet what a marked effect they have on its printing value.

If we look, then, at the subject of ratio of gradation, bearing in mind the distinction thus made in the application of the term density, it is not impossible that Messrs. Hurter & Driffield may be right in their deductions. Of two negatives of the same subject developed differently, one may possess twice as much *contrast* as the other when put to the printing test, although the ratio of gradation is precisely the same in both. It seems to have been assumed by some of those who have taken part in the discussion that similarity of gradation implies identity of printing effect whatever the density of the deposit may be; but this is far from being the case, as can, I think, be easily shown.

Let us suppose a very thin negative, in which the relative densities of the lowest and highest gradations are represented by the figures 1 and 4 respectively, and two of the middle tints by 2 and 3. Then, taking 0 as clear glass, we have a series in arithmetical progression, 0, 1, 2, 3, and 4, representing the full gamut of the negative from deepest shadows to highest lights. But the limit is too narrow to give printing value, the steps in this scale are too minute to be appreciable, or, at least, to give the necessary contrast. But let us imagine the image to be further developed, until, according to Messrs. Hurter & Driffield, the values are doubled, and the same gradations are represented by the scale, 0, 2, 4, 6, 8. The ratio of gradation remains precisely the same, but it will be noted that there is twice the interval between high lights and shadows and between the different gradations, and that therefore the contrast has been increased, and the previously inapplicable differences have now received a printing value. Here, it seems to me, is where the first misconception exists, namely, that to alter printing value or contrast it is necessary to change the ratio of gradation.

Looking at the fact, as has been pointed out, that everything depends upon the effect produced by the original action of light, it is difficult to conceive how the result of normal or correct development could be otherwise than the production of a definite and regular series of gradations directly dependent upon its varying degrees of force. When the developer commences to act, a number of molecules of silver bromide are reduced the more closely, or the greater number in a given space, according as the force of the light's action has been stronger; each of the molecules first reduced transmits the action to another, and that again to another, until the limit of the effect has been reached; and so the reduction proceeds regularly, and in proportion to the original force set in motion. This is the boundary line of legitimate development; if it be continued further, the reduction that takes place is irrespective of any effect of light, and occurs uniformly over the whole surface of the plate, and then it is that the ratio of gradation of the image is altered. For, suppose by forced or over-development a reduction takes place, it will have the form of a uniform veil over the whole image, and, setting its density value down as equal to 1, we must add that number to the value of each of the tints produced legitimately, with the result that the series 0, 2, 4, 6, 8, becomes 1, 3, 5, 7, 9, in which it will be observed there is no "deepest shadow" or clear glass, and all the other gradations are brought proportionately closer together, producing flatness. Contrariwise, if the development is stopped too soon, or before it has produced the full effect possible with the exposure, we must make a deduction all round from the values of the gradations, with the result that there is a superabundance of shadow and general heaviness.

It is obvious that the developer takes some time to perform its work, and that that time depends upon the force of the light's action; or, in other words, that reduction is more rapid in the higher lights or when the action has been strong than in the shadows when it has been much weaker, or perhaps scarcely appreciable. If it were not so, the formation of the image in all its gradation would take place instantly, as soon as the *vis inertiæ* of reduction was overcome, or the development commenced. But what is the fact? First the high lights appear, and as these gradually gather strength the half-tones are brought out and finally the shadows, and upon the correct adjustment of the development to the exposure depends the possibility of bringing out the faintest radiations before the high lights have acquired too much force. For every variation of exposure there is a variation in development necessary, but Messrs. Hurter & Driffield say that with a given exposure no possible variation of developer can alter the result so far as gradation is concerned.

This brings me back to the conditions under which they appear to have worked, namely, with the conditions normal and using the developer to the full extent of its legitimate power. This being the case, it is no wonder that the result as regards ratio of gradation is invariable; for, if a developer of medium power produce a certain result when pressed to its legitimate limit of utility, a stronger or a weaker will, as I have shown, only alter matters proportionately. But let the development be carried further than what they consider its proper limit, or let it be stopped before it has expended its full power, and alteration of ratio at once commences. If, as I believe, Messrs. Hurter & Driffield have ignored variation in time of development, they have overlooked one of the greatest powers the photographer possesses.

I have already said that the rapidity of the reduction depends upon the relative force of the light's action on various portions of the image; but naturally it is affected quite as much by the strength and character of the solution, and more still by the combination of the two factors. What I mean is that, whereas a developer of normal or medium strength may take three times (say) as long to develop out a faint shadow than it does to produce the high lights for negative, a weaker solution may take perhaps six times as long, or a stronger only twice as long. Obviously, unless such different developer be permitted to act to their full extent, they must exhibit some sort of abnormal result as measured from Hurter & Driffield's standpoint; in other words, they must, if they do not alter the ratio of gradation, at least "change the pitch," so to say, of the image by raising or lowering it on the gamut of tones.

For instance, let us suppose we have two similar plates exposed to the same subject under like conditions, and, on developing one with a normal developer, we find it much over-exposed, incapable of being brought up to printing density, and altogether wanting in contrast. What do we do with the next? Well, most likely strongly increase the dose of bromide and reduce that of the alkali. But, say Hurter & Driffield, "the result will be the same; you will have the same ratio of gradation, but greater density." So we might if we used each developer to its full power; but suppose we stop the second developer when it has only half performed its work. We shall find that the high lights have forged ahead, being comparatively little affected by the extra check, and, owing to the slowness of the development, have had time to acquire some density; the half-tones come on gradually, gaining strength as they grow, while the fainter shadows, and, above all, the veil or fog that overspread the first plate, are kept back still more. We have no wish that they should appear, so we arrest development just before their time comes, and so secure a result that, if not perfect, is still much better than the first. This is what the practical photographer does every day, and calls it "latitude in development."

Whether the ratio of gradation can be considered to have altered in this case, or whether the image has simply been pushed higher up the scale, may be argued by those who choose; but this seems one proof to me that, right or not right, Messrs. Hurter & Driffield's theory does not interfere with the photographer's pet idea of latitude in exposure.

W. B. Bolton.

CONTINENTAL NOTES AND NEWS.

Photography in Colours.—M. Louis Ducos du Hauron writes to a French contemporary to point out that Mr. F. E. Ives's method of obtaining coloured lantern positives by superposition of different coloured pictures was anticipated by himself and M. Charles Cros so long ago as the year 1869. He therefore claims that it is a purely French invention, which has only been copied in America.

Cresco-Fylma.—The *Photographic Gazette*, in which this

communication appears, goes in for a little attempted patent smashing on its account. After ridiculing the claims for novelty of this method of enlarging made by one of our English contemporaries, the *Gazette* informs us that the process in question is described in its pages for March 25, 1891, the inference, of course, being that the English inventors have been anticipated. Apparently all good things are invented in France, in which country, by the way, the victors of Waterloo are said by some people to have been born.

Another New Developer.—Dr. Eder is at present experimenting with a new developer, which he calls Metol, a substance with which he associates glycerine. It is said that this mixture surpasses in energy all developers known, and that it keeps better than them. Next, please!

Pyro an Antidote for Nicotine.—So says Dr. Gautelet, who recommends placing a pledget of cotton wool, impregnated with a ten per cent. solution of pyrogallic, in the bowl of the pipe, which will neutralise the nicotine condensed there. But a critic of the dodge—probably a member of the Anti-Tobacco League, and therefore hopelessly prejudiced—suggests that the best way to avoid the baneful effects of nicotine is simply—not to smoke.

Mica for the Carbon Process.—Sheets of mica, coated with bichromated gelatine, are now stated to be on the Continental market, thus obviating transference. It is said that the sheets are saleable in various sizes from 9 × 12 c.m. to 180 × 240 c.m. We do not know if the idea is a "patented" one; but, if so, as we pointed out in an article on the subject some weeks back, its validity is doubtful, as the application to mica for this purpose is not at all a new one.

Monument to Petzval.—The Photographic Society of Vienna has taken the initiative in raising a subscription for the erection of a monument to perpetuate the memory of Professor Petzval. The Society has opened the list with a donation of 1070 francs. Remembering the enormous services which this illustrious *savant* rendered to photographic optics, and in which this country has been as large a participant as any, we commend the project to English photographers and opticians, in the hope that they will not allow themselves to be unrepresented in the subscription list.

Souvenir of the Vienna Photographic Exhibition.—A superb album, containing thirty-seven photogravures of pictures, shown in the late Vienna Photographic Exhibition, has just been issued, English photographic art being represented by Mrs. S. Frances Clarke and Messrs. A. Burchett, Adam Diston, P. Lange, R. W. Robinson, Lyddell Sawyer, Ernest Spencer, F. H. Worsley Bennison, and A. R. Dresser. The art portion of the descriptive text is contributed by Herr Jacob von Falke, Dr. Eder being responsible for the technical details supplied. We hope our compatriots will not be unduly puffed up with pride at having their work shown among that of an Archduchess, a trio of Barons, a Countess, and a Prince!

Camera Positives.—M. P. Cardin, in *Cosmos*, publishes a method of obtaining positives direct in the camera on "ordinary negative paper." An exposure of from five to ten minutes, with a large diaphragm in full sunlight, is given, a weak developer being employed to develop the image, the details of which are already visible. It is said that a dark room might be dispensed with in development, provided that the operation be conducted in "the shade," the dish being covered. The picture is, of course, reversed, but this disadvantage disappears with pellicular supports. This "method," as our readers are aware, is founded upon the phenomenon of "solarisation," or "reversal."

Snow Statues Photographed.—During the recent severe weather, M. Buls, the Burgomaster of Brussels, devised a novel means of helping those who suffered most from the arctic inclemency in the Belgian capital. He appealed to a number of sculptors to decorate the principal walk of the Brussels Park with snow statues, an invitation that was most readily responded to. Admission to view the statues was by payment, which produced a sum of 11,000 francs. Among the subjects selected for treatment by the artists were bears, Pierrot and Pierrette, a bust of H.M. the King, &c. Photographs of these snow statues were taken by M. Alexandre, of Brussels, and reproduced in the *Bulletin* of the Association Belge; and they form a highly interesting memento of a novel experiment, which may be commended for imitation on this side of the Channel when opportunity—that is, a bounteous snowfall—next offers.

Taxing Amateurs.—Herr Brand, a Viennese photographer has suggested to the Finance Minister of his native country the levying of an annual tax of twenty-five florins on amateur photographers; but, the Minister having closed his eyes to this seductive idea for increasing the revenue, the aggrieved Herr Brand has delivered himself of a long letter to the Vienna *Tagblatt*, in which he lays bare his reasons for his suggestion. These are, of course, that amateurs are the ruin of professional photography, &c. He admits that there are some amateurs out of whom professionals make a profit, but these, he says, are in the minority. He bitterly complains of those who lend their cameras to friends, and who employ photography for commercial purposes, thus taking the bread out of the mouths of the ill-used professionals. He believes that a tax would change all this, by discouraging the employment of the camera amongst amateurs, and so bringing back a great deal of work to the professional. Herr Brand seems to have succeeded in nothing so much as getting himself well laughed at for his pains.

ON THINGS IN GENERAL.

With the Editor's permission I should like to make some comments which, I am afraid, cannot be made brief, on a subject of great importance—a letter on the 5th ult. from Mr. M. J. Michael, and Messrs. Hurter & Driffield's reply to it; for, from the absence of further response from the former, and the statements made by the latter, each correspondent seems ignorant of what these two experimenters did say in their paper. Let me at the outset say that this paper, read before the Society of Chemical Industry, is a monument of clear investigation and experiment which I, for one, value most highly; but, while giving all honour to its writers, I think it undesirable the facts should be obscured. The greatest investigators are liable to error, but it is not often that they betray such ignorance of their own work a short time after its publication as do these authors in this instance.

Mr. Michael's letter and Messrs. Hurter & Driffield's reply may, for the present purpose, be summed up in the following quotation from that reply: "Mr. Michael is, apparently, under the impression that we hold that the ratio of gradation is unalterable, not only by modifications in the constituent parts of a developer, but that it is invariably the same whatever the developing agent employed. The former we do hold, the latter we do not. In our original paper we distinctly say: 'There is a theoretical possibility that a plate may be rapid to one developer and slow to another, so as to require different exposures, according to the developer used.'"

Let us go to the original paper, as reprinted from the above Society's *Journal*. The unfortunate point about quotations is that they may be said to be garbled. I endeavour to give the just context, and I refer those interested to the quoted portions by indicating the page. The italics are my own. Page 6: "If two different densities be developed upon the same plate to their extreme limits, the ratio existing between the limits must depend solely upon the action of the light. The question we have now to consider is whether it is possible, by *any modification of development*, to influence this ratio." Page 7: "The results clearly show that the ratio of densities is given by the light alone. . . . . This ratio, we find, is *altogether unalterable*. No modification we have made in developers or development has ever seriously disturbed this ratio of the densities." A "Manchester Slow," having received three different exposures, was cut into four portions; two were developed with hydroquinone, and two with

eikonogen." Page 8: "The result"—other plates being used (F. L.) - "is extremely interesting and important, since it shows that the ratio between the various densities is identically the same *whatever* developer is employed, except in the case of eikonogen, in which the ratios are a little different. . . . . These experiments all confirm the statement that the gradations of a negative, as expressed by the ratio of the densities, are independent of the time of development, cannot be affected by alterations in the composition of the developers, and are almost *identically the same, whatever developer* is employed. We are thus driven to the conclusion that the photographer has no control over the gradations of the negative . . . . by no means at his disposal can he alter the ratios existing between the amounts of silver reduced in the various parts of the negative; they are regulated entirely by exposure."

How, after these portions of Messrs. Hurter & Driffield's paper being brought forward, can they say they "do *not* hold" that "the ratio of gradations" "is invariably the same, whatever the developing agent employed?"

I do not at this stage wish to complicate the plain point at issue by endeavouring to prove that the universal practice of photographers to alter the ratios by modifications or changes of development is founded on possibilities. For the present I simply state, as an expression of personal opinion, that the ratios can be changed at will.

The remarks in my last upon the wise provision of the Editor in supplying in the ALMANAC tens of thousands of instances year by year, to show the liability of bromide prints to fade, or otherwise, were quickly taken up, and at a meeting of the London and Provincial Photographic Association it was pointed out that some ALMANAC pictures had faded. Afterwards, a good explanation was given why some had faded, and it must be admitted that almost any process, if worked improperly, may give fugitive results. But, at the same time, no process will readily obtain a good reputation unless a disclaimer is made before fading has made itself evident. Bromide prints are very valuable, but no photographer has any justification whatever for representing them as absolutely permanent, and he who does so, in my opinion, dishonestly handicaps those who, at greater expense, issue prints that can justly be entitled permanent.

Those interested in lantern matters who have not read the description, by Mr. H. Brier, of the method of testing the stability of gas cylinders after their power of withholding pressure has been proved, should look up their back JOURNALS and read that gentleman's letter on page 126. When chains and cables are tested as to their ability to stand certain strains, the question has been often raised as to whether the testing itself may not have reduced the strength; but as to the cylinders no question need arise. The extremely ingenious method described enables any ordinary workman to ascertain whether or no a permanent stretch has been given to the metal.

I feel it desirable to call attention to a letter recently published in these pages, recommending a method of calming the surface of water when covered with ripples. The plan was to throw oil on the surface, and so still the waves. This is, indeed, a retrograde plan. When I have a view to photograph in which important objects are reflected in a lake or pond, it is always my aim to partially destroy those reflections, for nothing is more hideous to the artistic eye than to see a handsome building, for instance, so reflected as to show all its details below as well as above the horizon. No, instead of stilling waves, let me recommend that they be produced, and, if a sheet of water "reflects beautifully," let the photographer pitch a stone therein just before taking off the lens cap; the view will be twice as valuable.

FREE LANCE.

CARBON PRINTING.*

RAPIDITY, COST, &c.

As regards speed of printing and working, compared with other processes, I find it pretty quick working, decidedly quicker than ordinary sensitised albumenised paper. In the rather poor daylight of December and January, working in the shade of a building, the average time of exposure in the printing frame seems to be about twenty minutes for each "tint" of the actinometer required—that is, for a negative requiring two actinometer tints, forty minutes; one requiring four tints, one hour and twenty minutes; but, in the brighter weather of summer, and with white fleecy clouds in the sky, the time will be reduced to half that. I am convinced that, in dull weather, in the best part of a winter day, it is comparatively easy to make prints from dense negatives in one hour and a half, which would take a whole day, or even two days, with platinotype or weakly silvered albumenised paper.

Speed of work in development will depend mainly on one's appliances and method of working, but in my own case I can develop and finish off half a dozen 12 × 10 prints (including the time taken to heat the water to 96° in one hour and a half.

Perhaps it may interest you to know something about the cost of production, and I consider carbon work one of the cheapest processes we have, provided no waste prints are made; but as the element of waste is common to all processes if sufficient care is not observed, carbon work is not singular in that respect. As I said before, when once the correct actinometer time has been ascertained by the experiment, all subsequent prints from that negative ought to be a certainty, and therefore no waste prints ought to be made. I find for my size of print (11 × 9) the cost of production (apart from waste) is about three shillings and sixpence per dozen. There is no chemical required except alum, and that is so cheap as to be outside of calculation; only hot water is needed, and the glass supports can be used over again indefinitely if care be taken against breakage. Calculations made for whole-plate and half-plate negatives should come at about 2*s.* and 1*s.* per dozen, and ought not to exceed 2*s.* 6*d.* and 1*s.* 6*d.* respectively. Those who work much in bromide or platinotype at present prices, can tell for themselves what difference they find.

Finally, I think that if you will give the process a trial, you will be so pleased that you will probably take it up with as good results as any other process you may have tried. To me, one great point of its appreciation is the knowledge that the prints are permanent; as beautiful in quality as platinotype, and at far less cost of production.

GEORGE BANKART.

* Concluded from page 136.

THE "THEORY" OF DEVELOPMENT.

[Paper read before the Photographic Club.]

AMONG the numerous operations connected with the production of a photographic picture, all offering special points of interest, there is none which possesses the same fascination as the development of a negative. No item in photographic manipulation has originated more discussion in the technical Press, or at the meetings of Photographic Societies, and still we are bound to admit that little more is known about the actual transformation which the silver haloid undergoes during exposure than what had been already suggested by the earlier observers.

Our subject for to-night bears to my mind a somewhat misleading title. How are we to discuss the theory of a phenomenon when we know little or nothing about the nature of the latent image, which forms the basis of development? A scientific theory is essentially based on well-established facts, and no speculation deserves the appellation of theory which does not satisfy this requirement. There is probably no word in the English language which is more often misused than the word Theory. What has often been called "Scientific Imagination," is put forward as a theory. Is there any wonder that occasionally theory of this kind disagrees with practice?

In opening this discussion, I cannot pretend, therefore, to lay before you a theory. All I can do is to submit to your consideration the various hypotheses which have been made on the subject, none of which may represent the actual truth, however well they may appear to explain the phenomena observed during the development of the negative image. Before entering on the question of development, we may profitably examine the material we have to deal with, and give a few minutes to the nature of the film, which carries the latent image we are about to develop.

FORMATION OF THE LATENT IMAGE.

Negative films are composed of silver haloids, suspended in an organic vehicle, which may be gelatine or collodion. In the case of the modern dry plate, bromide, sometimes with a small proportion of iodide of silver, is emulsified in gelatine. As far as I have been able to ascertain, no writer on this subject has ever hinted that, during the process of emulsification, any chemical action took place in which the organic vehicle, gelatine or collodion, was involved. In all cases, the sensitive part of the film is admitted to be solely composed of silver haloids. The action of light on the sensitive salts of silver has never been determined, so as to leave no room for doubt as to the nature of the transformation which takes place during exposure. Though the existence of the sub-bromide of silver has never been proved, and, indeed, does not seem in accordance with the teachings of the atomic theory, the time-honoured hypothesis of a sub-bromide of silver being formed by the action of light on the normal bromide has been handed down from text-book to text-book.

Of late, the fact that the presence of air and moisture seems to have a certain influence, has led to the presumption that an oxybromide

of silver might be the result of the action of light. However, this has not, so far, been substantiated. One thing seems to be certain, the formation of the latent image is a chemical process and is not due to mere physical action. It has been established, without doubt, that when light acts on one of the silver haloids, part of the contained halogen is evolved. This is amply demonstrated by a very elegant experiment, due to Professor Meldola, and which was shown by him at one of his lectures at the Royal Institution.

It had been suggested by some observers that part of the haloid having lost its halogen by exposure to light, the residual product was a mixture of unaltered haloid with reduced silver. The fact that silver chloride, immersed in strong nitric acid, darkens when exposed to light, shows the fallacy of this assumption.

Whatever the case may be, we known that chemical decomposition has taken place, and that a certain portion of the silver haloid has been transformed, yielding what we will call, in our ignorance of its nature, a "reduction product." It is this reduction product which, submitted to the action of suitable chemical solutions, yields the nucleus of the developed image. It must be noted, however, that the quantity of silver bromide which has been transformed during exposure is very minute indeed. The silver reduced from it would be totally insufficient to account for the quantity of metal present in the fully developed negative.

Causes of Density.

Every photographer is aware that, if the developer is washed off as soon as all the detail in the picture is visible, the plate, on fixing in the usual way, will show the merest ghost of an image. It is only by a prolonged action of the developer that density is obtained. This affords ample proof that density is not the result of the exposure alone. The balance of the silver forming the image must, therefore, be sought from some other source.

Ammoniacal pyrogallol dissolves a minute proportion of silver bromide from the film, but certainly nothing like the quantity necessary. There is no doubt that the surplus metal is derived from the unaltered bromide in the film, which, under the combined action of the developer and of the metallic silver reduced from the modified bromide, decomposes in its turn.

A classical experiment by Captain Abney shows conclusively that the accretion of density is derived from the haloid remaining in the film. An exposed gelatine plate was coated with colledion emulsion on one-half of its area. It was then developed, and the portion covered with collodion emulsion proved to be denser than the other half. On stripping the collodion film, the image was found to be impressed on it also. This certainly indicates that an action has taken place during development, which has affected silver bromide, which had not been exposed to light. This phenomenon has been explained by an action which should take place between the silver reduced by the developer at the start and the unaltered silver bromide. An electro-chemical action is set up according to this hypothesis, in which the silver in a nascent state would form the cathode of an electric couple, in which the anode would be constituted by the silver bromide in the film. This hypothesis has in its favour the fact that it has been possible, by imbedding minute particles of silver in a wetted gelatine bromide film, to make these the nuclei of progressive development in a plate which had not been exposed to light. The conditions under which this experiment took place were such as to preclude the results from being ascribed to the effect of pressure, or, as it is called, "shearing stress." Following out, however, this electro-chemical hypothesis, it is necessary that a sufficient quantity of reduction product should have been formed by light all over the picture. If the silver deposited from this reduction product is not in sufficient quantity, the potential of the metal will not be sufficiently great to overcome the resistance which silver bromide offers to decomposition.

It has often been said that, however short the exposure, we ought to be able to develop the picture. Unfortunately, the means we have at our disposal are not, so far, powerful enough to cope with very much reduced exposures, and there is no doubt that it is absolutely necessary that the action of light should have lasted long enough to effect the reduction of an appreciable quantity of silver haloid even in the deepest shadows of the picture.

If the reduced silver, set free by the first action of the developer, be in too small a quantity, the image fails to build up, so as to attain the required density. In other words, in the parts of the negative which have been less brilliantly illuminated, only faint indications of detail, or even no trace of an image, are obtained. This is the case in an under-exposed negative.

The Function of Gelatine.

The phenomena produced by over-exposure are of a very much more complex nature. In order to arrive at a satisfactory explanation of the facts observed, it will be necessary to say a few words on the function of the gelatine which holds the silver bromide in suspension. Silver bromide obtained by precipitation, and exposed to light in a state of purity, is not very sensitive. If, however, it is placed in contact with a substance capable of absorbing the liberated bromine, the sensitiveness to light is enormously increased. The bromine, or, in general, haloid absorbents, are of various kinds, according to the process adopted in preparing the film. They are usually termed "sensitisers." In the Daguerreotype plate this function was filled, to a certain extent, by the metallic surface of the plate. In the wet-collodion process, the free nitrate of silver, which remains in the film, absorbs the bromine set free by the action of light. Lastly, in the gelatine dry plate, the gelatine is the sensitiser. The quantity of reduction product, formed by light in a given film, will be, within certain limits, proportional to the duration of the exposure. The gelatine will continue absorbing the liberated bromine till it becomes saturated with the halogen. At that moment, the brominated gelatine seems to have the property of rehalogenising the reduction product, so as to transform it back into normal bromide. This action may proceed far enough to reconvert, in the more brilliantly illuminated parts of the picture, the greater portion of the reduction product. On development, the high lights are thin or even transparent. This is what is termed solarisation or reversal. If a plate has received a sufficient exposure in the camera, the high lights of the picture may give, on development, a positive, instead of a negative, image. This reversal, however, need not necessarily be complete. Part of the reduction product may have been reconverted, the remainder being still capable of development. It is now easy to understand why an over-exposed negative should be one rendering all the detail in the subject, but which is flat, wanting in contrast, and thin as regards printing density. Meldola, in his *Chemistry of Photography*, draws attention to another very important fact, which, to my mind, throws some considerable light on the appearances observed during the development of an over-exposed plate.

Gelatine which has absorbed a considerable amount of bromine, set free by the silver salt in the film, becomes very much less permeable to aqueous solutions. Of course, when we speak of a "considerable" amount of bromine, we mean relatively to what would have been evolved during a normal exposure.

This being the case, the developing solution will not permeate the high lights as rapidly as it does the less exposed parts of the film. Development, therefore, proceeds more energetically as regards accession of density in the shadows than in the high lights. If, at the same time, we consider that the partial reversal of the high lights may have taken place, leaving less reduction product, it will be easily understood why the image should be thin and wanting in contrast. In fact, under certain circumstances, a strong developer yields a positive, when a weak one would have given a negative, image.

Nature and Influence of Reagents.

We have now endeavoured to explain the action which takes place during exposure and development. We have next to consider the nature of the chemical solutions used, the influence of each constituent on the final result, and, last of all, to examine whether the various hypotheses made are in accordance with the actual practice of development, as carried out by photographers.

Leaving on one side iron development, which appears to allow of much less possibilities than what has been termed alkaline development, we may define a complete developer as constituted by three factors, viz., a reducing agent, an accelerator, and a restrainer, these three chemicals being compounded in variable proportions according to circumstances of exposure, nature of subject, as also to the effect desired.

I think we may take pyrogallol as the type of the reducers generally in use, hydroquinone and eikonogen having the same mode of action, the only difference being in the relative energy of the last-named bodies. Pyrogallol in a neutral solution has but little energy as a reducer, and still less if in an acid solution. If, on the contrary, an alkali, such as ammonia, is added to it, it becomes a powerful reducer, of which the activity increases, in a certain measure, with the degree of alkalinity in the solution. Alkaline pyrogallol can be prepared that will instantly decompose the silver bromide on an unexposed plate, and produce what is called chemical fog. In the developer it is the pyrogallol which both develops and gives printing density. The other elements simply modify its action.

If a soluble bromide, such as potassium or ammonium bromide, is added to the developer, the alkalinity of the solution can be increased considerably without inducing fog. This is of great value when, in cases of under-exposure, a very energetic developer must be used to force out detail.

The soluble bromide appears to form, with silver bromide, a double salt, which, though still capable of reduction, is much less easily

reduced than the normal salt. This property of soluble bromides in the developer enables the photographer, as we shall see later on, to overcome certain difficulties which, without it, might prove unsurmountable. Pyrogallol and ammonia, used alone, will, in many cases, attack the unaltered haloid in the plate before the development of the latent image has had time to be completed. An admixture of soluble bromide lessens this evil to a very great extent, and, in fact, with some plates, cannot be dispensed with. It must be borne in mind that, with an exposed plate, it is very difficult to avoid a certain amount of decomposition in the unused bromide, if the developer employed be very strong.

The aim of the operator should be to reduce only that part of the haloid which has been modified by light. The developer should not decompose directly the unused bromide of silver. This, as we have already said, should be reacted on by the deposited silver, so as to form a fresh quantity of reduction product, which, being in its turn attacked by the developer, yields the increased density of deposit sought for. The alkali, or accelerator, simply increases the energy of the reducer, rendering its action more rapid, more searching, so as, in many cases, to enable one to force out insufficiently impressed detail. We will now examine what takes place in the three well-known varieties of exposure, and endeavour to see, at the same time, how facts agree with the explanations suggested:

Normal Exposure.

Every part of an illuminated object reflects light of an intensity proportional to that which it has received, subject to certain conditions of colour and nature of surface. In the special case of photography, we have only to deal with the actinic intensity of the reflected light, and this is, unfortunately, very much more influenced by the colour of objects than the visual rays. A normally exposed negative would be one in which each portion of the subject would have impressed itself proportionally to its actinic value, or, in other words, a negative in which each degree of light intensity would be represented by a strictly proportional quantity of reduction product. This definition, I need not say, is never realised in practice, but approximations can be obtained to this ideal, and these constitute the simplest case of development. In dealing with a correctly timed negative, the main object should be to avoid any veiling or fog. The introduction of this defect would at once destroy the advantages of correct exposure, and would affect seriously the scale of gradation in the picture. A slight veil may make little or no difference in the high lights, while it would be very perceptible in the half-tones, and still more so in the shadows. A veil is sometimes said to be an advantage in printing thin negatives. I do not think, however, that it should be introduced during development. There are plenty of means of doing this after the negative is finished. This being the case, a developer must be compounded which will do its work with relative rapidity, so as not to leave time for the unaltered haloid to be attacked by the reducer. It will contain the full amount of alkali, and a small amount of soluble bromide to keep the plate clear. Of course, the pyrogallol is varied according to the nature of the subject. What is alluded to here is always the quantitative ratio between the alkali and the reducer. Development proceeds gradually, though rapidly, each portion of the image building up proportionally to the exposure it has received. In this hypothetical case, the shadows possess the required density when the high lights have become sufficiently opaque. I need not say that a correctly timed negative is the exception; photographers generally prefer to expose fully, as development allows of a certain latitude in this matter.

Under-exposure.

In a negative of this kind, the high lights are fully impressed; the shadows, on the contrary, have not received sufficient exposure to form the requisite amount of reduction product. I have already pointed out that, with our present means of action, it is indispensable that a certain quantity of the reduced haloid should have been formed by exposure. If this is not the case, the metallic silver liberated by the first action of the developer will not be sufficiently abundant to start the electro-chemical action on which the building up of density is dependent. If the case of under-exposure is not hopeless, there will be, however, a small proportion of reduced bromide even in the deepest shadows, and this will develop, though very slowly, and at a rate which will not keep pace with the gain in intensity of the more brilliantly illuminated parts of the picture. If such a negative were developed in the ordinary way, the high lights would be absolutely opaque before the shadows had even started development. And, on account of the short exposure, it is indispensable to use a strongly alkaline developer to bring out what detail may exist in the shadows, or, in fact, to start action in them. We are thus placed between two equally unfavourable cases. Either we get a negative with high lights of printable density, and patches of clear glass for the shadows, or we obtain better-rendered shadows, with the high lights entirely opaque and therefore devoid of detail. In both cases the result is useless as far as picture-making goes. We have, however, a means of producing a more harmonious result, suggested by the various considerations which we have examined above. It is quite certain that the rapidity with which a negative gains in intensity is much more dependent on the quantity of pyrogallol present in the developer than on the alkalinity of the solution, though this factor has some influence. At the same time, the amount of detail obtainable from a given exposure does not seem to be affected in any great degree by a variation in the concentration of the reducer, but is brought out the more rapidly that the solution is more alkaline. Taking these facts into account, the most suitable developer for an under-exposed plate would contain just enough pyrogallol to start development, a large proportion of alkali, so as to set up energetic action in the shadows, and the smallest quantity of soluble bromide that will prevent the increased alkalinity of the solution from inducing fog. With such a developer, the high lights would remain very thin for a considerable time, the detail in the shadows coming up under the influence of a solution strong in alkali. When the whole of the picture has thus been brought out, it will be wanting in density, and quite unfit for printing if left at this stage. The minute quantity of pyrogallol employed, though sufficient to start development, has not been able to promote any great accession of density. It will be noticed, however, that the scale of gradation is much nearer to what it should be, and, at all events, much more satisfactory than what could have been obtained by the use of a normal developer. At the same time, silver has been reduced in every part of the picture, and this deposited silver will enable us to start further decomposition in the unaltered bromide, and so obtain density of deposit. An alternative method has been suggested, with a view to enhancing still more the obtention of detail without undue accession of density in the high lights. Many operators advocate soaking the plate in an alkaline solution, containing the requisite soluble bromide to protect the film from fog, but no reducer. After this solution has been allowed to act for a few minutes, a small proportion of pyrogallol is added, and development starts. The action of the reducer is rendered still more gradual by this plan, while the detail in the shadows is dealt with very energetically. Whichever of these modes of procedure has been adopted, the deposit obtained, so far, will be very weak, and our next step is to promote the accession of density, without which the plate would be worthless. At the same time, the treatment selected must be such as shall not disturb what scale of gradation we have succeeded in establishing. Here, again, the facts we have had under consideration furnish us with the means of attaining our object. Pyrogallol, we have said, gives density, but this action is, at the same time, proportional, as regards rapidity, to the degree of alkalinity of the solution. A strong solution of pyrogallol, made only very slightly alkaline, will act slowly on the deposit and will cause all parts of the picture to gain density, proportionally to the amount of reduced silver they already contain. At the same time, the alkalinity of the solution will be too much reduced to allow of any change being made in the contrast which exists already between the various lights of the picture. The very alkaline developer first used should, therefore, be washed off, and a fresh solution, strong in pyrogallol, and containing very little alkali, should be applied, when, if the exposure has not been hopelessly short, a negative should be obtained possessing fair gradation and printing density.

Over-exposure.

This case, which is by far the most frequent, is much more amenable to treatment than under-exposure. I have already gone fully into the nature of an over-exposed plate, and I think I have shown what would be the result of treating such a case with a normal developer. The considerable quantity of reduction product formed in the film by over-exposure will yield, on the first action of the developer, a large quantity of metallic silver, and this, combined with the developer, will reduce the unaltered haloid before it has had time to undergo the intermediate stage of decomposition, already alluded to several times. The picture "flashes" out, and refuses to take up density. The first step to take, where over-exposure is know or suspected, is to overcome the differences of permeability in the various parts of the film, differences which appear, according to Meldola, to be of considerable moment. The rapid reduction of the unaltered haloid by an increased proportion of silver from the reduction product must also be guarded against. Development should be slow and gradual. This will prevent all the silver from the reduction product from being set free at the same time. If an increased amount of soluble bromide is put into the developer, so as to mitigate the too rapid reduction of the unaltered haloid, the effects of the prolonged exposure will be rendered much

less harmful. The plate should, in consequence, be soaked for a sufficient time in a strong and neutral solution of pyrogallol, containing an increased amount of soluble bromide. This solution will permeate both the soft and hardened parts of the film, while the soluble bromide will form, with the unaltered haloid, the more stable double salt. A strong solution of pyrogallol is recommended, because, as we have already noticed, density is proportional, in a certain measure, to the concentration of the reducer. A very small quantity of alkali is now added to the developer. The action of the alkali is rendered still more gradual by the fact that the pores of the gelatine being filled by a plain solution of pyrogallol, this must be displaced by the now alkaline solution before action can start. If the exposure has not been sufficiently prolonged to give an undue amount of reversal, there will be a gradual gain of intensity in the lights, and these will, under very slow treatment, attain relative opacity before the shadows have made too much progress. Ample time must be given, excess of alkali guarded against, when, in many cases, a good negative will be secured. Hydroquinone and eikonogen have a similar mode of action to that of pyrogallol. They appear, however, to have a lesser tendency to act on the unaltered bromide of silver. This explains why many writers have dispensed with the use of soluble bromides in conjunction with these reducers. I have refrained from making more than a mere reference to iron development. This is much less under control, and does not seem to give anything like the amount of latitude in cases of incorrect exposure. In reality, it is by far too energetic for delicate treatment. As will be seen, the methods of development suggested above are fairly well in accordance with the various hypotheses and explanations I have endeavoured to make clear to you.

Free Silver in Wet Collodion Development.

Though the use of wet collodion is now restricted to a small number of applications, the mode of action of the developer is such, that I think it right to say a few words about it, if it were only to show the variety of ways in which the accretion of the silver forming the image can take place. The sensitised collodion plate is exposed while still wet. The solution of silver nitrate retained in the pores of the film is, in this case, the bromine absorbent, or sensitiser. If a wet plate be *thoroughly* washed after sensitising, and then exposed, it will prove to be reduced in sensitiveness. The presence of free nitrate of silver is therefore indispensable. After exposure, the plate is developed by ferrous sulphate, to which a quantum of acetic acid has been added. Here, again, the free silver nitrate plays an important part, as the silver with which the image is fed is derived from it, and not from the haloid in the film, as in the gelatine process. That this is a fact can be shown by washing away the free nitrate of silver after exposure. If iron development is then attempted, no image, or, leastwise, a very faint one, will be developed. The addition of a few drops of silver nitrate to the developer will, however, start development. The acetic acid has the same function as the soluble bromide in dry-plate practice, and moderates the action of the ferrous sulphate, which, if used alone, would at once fog the plate. In comparing the gelatino-bromide with the wet-collodion process, it may be said that the first action of the developer is identical in both. During exposure a certain quantity of reduction product has been formed by the action of the light on either film, and this is reduced to the metallic state at the very outset of development. It is the after-process of growth of the metallic deposit which differentiates the two methods. In the gelatine process, as we have seen, the silver is supplied by the unaltered haloid in the film. In the collodion process it is obtained from the free nitrate of silver on the plate. It may be said that, in the gelatine plate, the image is fed from beneath, whereas, in the collodion film, it is fed from above. I often hear it said that silver is precipitated on the image during development. This expression is entirely wrong, and gives no idea of the action which takes place. The mode in which the silver appears to be fixed is similar to that observed in the electroplating of metals. The metal is not precipitated in galvanoplastic operations, it is fixed by the cathode by a kind of molecular deposition. There is a very great difference between the two modes of action.

Platinotype Development.

The remarks I have made would probably not be deemed complete f I did not allude to printing processes by development. The gelatino-bromide paper for positives calls for no special remark. The action of the developer is similar to that described for negative work. In the platinotype hot-bath process, the prints have to undergo development, but the process is of a quite different nature to those we have examined so far. The object of the developing solution is mainly to bring the ferrous oxalate, formed during exposure, into solution. It can then act on the potassium chloroplatinite. The ariations in the temperature of the bath simply modify the energy f the reaction between the two salts. In contrast to what takes place in the development of a negative, this is really a case of precipitation of metallic platinum from the chloroplatinite of potassium.

In closing these remarks, it may be asked what benefit we should derive if the true nature of the transformation, which silver haloids undergo during exposure to light, were known. It is not probable that we should learn thereby to use our actual developers with more effect. Long practice and experience have taught photographers how to meet most cases in the development of their negatives. What we must hope for in the disclosure of a reliable theory of photo-chemical action is the means of discovering and applying new agents to the work of development, agents which shall be free from the discrepancies which we have found in our old and, so far, trusted developers. We may then be able to discuss the "theory" of development; what we are doing to-night is simply to compare one with another—the various aspects of the question. We cannot have the pretension of being in possession of anything more than a few experimental facts, and some more or less plausible speculations as to their nature.

Adolphe M. Levy.

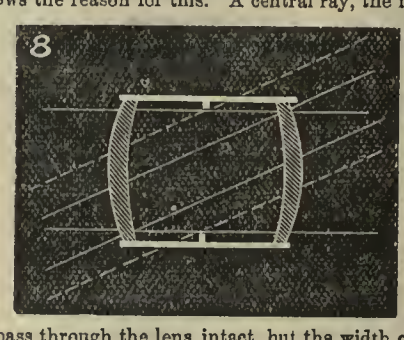
ELEMENTARY NOTES ON PHOTOGRAPHIC LENSES.*

The Rapid Rectilinear Lens.

For moderately rapid, architectural, and copying work, the standard type of lens is the rapid rectilinear, or rapid symmetrical, as it is sometimes called. This consists of a concavo-convex cemented combination, mounted at each end of a tube, the convex side being towards the end of the tube in each case; and, from the previous illustration of the curvilinear distortion of a single lens, it will be apparent that, on account of the stop being placed behind one and in front of the other, the tendency of one to distort inwards is neutralised by the outward tendency of the other, and mathematically correct projection is obtained. The two combinations being turned in opposite directions relative to the sensitive plate, the spherical aberration of one is corrected by that of the other, and brilliant definition can be obtained with the full diameter of the lens, this rendering it very rapid.

Where great variety of work is done, it is the most useful of all lenses, sufficiently rapid for portraits in a well-lighted studio, and, for all ordinary instantaneous work; it is very useful for general outdoor purposes, and absolutely necessary for architectural, mechanical, and copying where perfect accuracy of projection is essential.

For landscapes it is not quite so good as a single lens, by reason of its increased number of reflecting surfaces, four; and two of these are concave towards the plate, while in the single there are only two surfaces, and neither of these concave in the same direction. But opticians have been more successful in curing the rapid rectilinear of the defect of producing "ghosts" than the portrait, as they very rarely appear, though they probably exist in a diffused form, and prevent the image from being so crisp and brilliant as it would otherwise be. A second, though perhaps slight, objection is, that the face of the front lens is exposed to such a glare of diffused light, independent of that forming the image, though a sky-shade would be an efficient protection against this. A third objection is inequality of the amount of light reaching different parts of the plate when the larger stops are used, the beams of light forming the margins of the picture being much smaller in area than those in the centre. Diagram 8 shows the reason for this. A central ray, the full diameter of



the stop, can pass through the lens intact, but the width of the marginal ray is determined by the extent to which it is cut by the lens mount, or the portion that the lens itself is capable of transmitting. The full diameter of the stop is shown by the dotted lines. In negatives exposed under those circumstances where full advantage has to be taken of the rapidity of the lens, this inequality of illumination is a serious objection,

* Continued from page 138.

as the centre of the plate frequently develops denser than the edges, and this detracts strongly from the value of the gain in rapidity.

Wide-angle Lenses.

On the subject of wide-angle lenses, the greatest misconceptions exist in the minds of those who have given the subject of lenses little or no consideration. The width of angle included depends on the ratio of focus of lens to size of plate, and is in no way influenced by the form or construction of the lens. A wide-angle and a narrow-angle lens of eight inches focus each would produce absolutely identical images on a half-plate, the difference between the two lenses being the capability of one of including a wide angle or covering a much large plate, while the covering power of the other is more limited. If a rapid and a wide-angle rectilinear of six inches focus each were attached to a 12×10 camera in turn, it would be seen that the "rapid" would only illuminate a circle of six or seven inches diameter, and all the remainder of the focussing screen would be dark; while by substituting the wide-angle lens the illuminating circle would probably be increased to thirteen inches, or double the diameter of the other, but all within the six-inch circle, the actual sizes of all the objects and relative positions being exactly the same in each case.

A lens may be said to include a wide angle when its focus is not greater than the longer side of the plate. It may be described as a wide-angle lens when it is capable of covering a plate whose larger side is equal to or greater than its own focus.

There is no type of lens that has been so injudiciously used as the wide-angle, and a beginner should be very cautious in availing himself of its advantages. As a general rule, it is advisable not to use a lens of shorter focus than one-and-a-quarter to one-and-a-half times the longer side of the plate—frequently a longer focus is a decided advantage under very special circumstances a shorter focus must be used. Experience is the best guide if general principles are appreciated.

Including a wide angle generally produces the effect of very exaggerated perspective, though this appears somewhat inconsistent with the previous statement, that the size of the objects is directly proportionate to the focus of the lens; the reason is that, having decided on a given amount of subject, a wide-angle and a narrow-angle lens would not be used from the same standpoint to include the view. An example will assist in explaining this: A photographer is arranging a view in which he wishes a cottage to form the principal near object, and some distant hills appear just about the same height of the cottage, which is, say, four inches. Now, if a lens of half the focus is substituted, the hills would still be just level with the cottage roof, but both would be reduced to half their former size, *i.e.*, about two inches high, and the cottage would lose its importance, and the foreground would be occupied by objects that the other lens would not include. In order to get the cottage the same size as before, the camera is moved much nearer to it; but this change of position is not sufficient to make any appreciable alteration in the height of the distant hills, which remain about two inches, only half the height of the cottage, and, in consequence, they appear dwarfed and insignificant, and, by contrast, the cottage conveys the impression of being an enormous size, this effect being quite different from the rendering of a similar cottage and smaller hills by a long-focus lens, as in the wide-angle view the extreme convergence of the perspective lines is a potent factor in producing the strained effect equally as the relatively large size of near objects contrasted with the diminutive appearance of the distance. The wide-angle rectilinear is similar in construction to the rapid, the combinations being mounted very close together, and specially designed to transmit oblique rays well. Their principal use is for engineering and architectural subjects, both interior and exterior, where a large amount of subject has to be included from a very near point of view. Their limit of covering power is generally a plate whose longer side is one and a half times their own focus, or about double that of a rapid rectilinear, though it is never advisable to work them to this limit if it can be avoided, on account of the undue prominence given to near objects, and comparatively small size of the more distant. In equality of illumination they are better than the rapid type, but this is principally due to the fact that they are used with smaller stops.

The wide-angle single is intended for those landscapes where the position is too confined to obtain the desired amount of subject with an ordinary single lens, to which they are almost identical. Their focus is generally about the same as the size of the plate they are intended to cover.

The *universal* lens, or *curvscope*, is a rapid rectilinear of very large diameter, and, the construction allowing full advantage to be taken of this increased size or light-transmitting power, it is considerably more rapid.

Henry W. Bennett.

(To be continued.)

EASTMAN PHOTOGRAPHIC MATERIALS COMPANY, LIMITED.

The shareholders in the Eastman Photographic Materials Company, Limited, have every reason to be satisfied with the progress which the business is making under the able direction of the board of management. The Kodak camera is now a household word, and "to kodak" will shortly take its place in Nuttall as a convenient verb to signify photographing instantaneously. The difficulties which the Company have had to contend with have now passed away, and apart from the very satisfactory piece of information that during the past year there has been an increase of 7000*l.* in the turn-over, there is also the prospect that in the future the new buildings and plant just erected will be able to produce the Eastman Film to the extent of about 1000*l.* per week. There will therefore be no difficulty in supplying the demands of the public, and the inability to turn out orders quickly enough will be a thing of the past. Under all the circumstances, the dividend of ten per cent. on the Preference shares, and seven per cent. on the Ordinary shares, must be considered as highly satisfactory, as it warrants the assumption that, when the photographic season arrives, the business will produce much larger profits than heretofore.

Colonel J. T. Griffin occupied the chair at the annual meeting, held on Monday at Winchester House. In moving the adoption of the report and accounts, he said: I am happy to congratulate the shareholders on the gradually increasing business of the Company. It has not been in all respects so rapid as we could have desired, but you must remember the difficulties with which we have had to contend. Our business has been in all respects successful and prosperous; but from circumstances wholly beyond our control we were unable for months to supply the demand of our customers. Our friends in America were engaged as well as ourselves in the erection of new and larger works, and they were unable to supply us with goods from that side of the water. We, using all diligence, were unable to complete our works, so that we could manufacture film and other material, until the month of August. These difficulties are now overcome, and we have in hand a large stock, not only of film but of Kodaks, we believe, sufficient to meet any demand which may arise. We have now the capacity to produce film to the value of 1000*l.* per week in anticipation of the trade which we hope to have. In addition we have nearly 10,000*l.* worth in stock. But, while our progress has been somewhat less than was anticipated, we are able to show an increase of 7000*l.* in the business done during the year, and we look forward most confidently to a large increase of this business and a corresponding increase of profits. There is one point to which I ought to call your attention. You will note from the balance-sheet that we have not written off anything for what are termed patents and goodwill. This course has been adopted after due consideration and consultation, not only with our solicitors, but with our auditors and others. We think that the time has not arrived when it is necessary to write anything off the sum which stands in the balance-sheet for patents. It will be remembered, when the Company was formed the original Eastman Company had been doing business for some time in England. The English Company took over the business as a going concern, together with the stock and patents. No specific sum has ever been mentioned as representing the value of the patents. But we assume that the patents are good and valid ones, and that their value for the time being is increasing, and that for a year or two it will not be necessary to write off anything on their account unless our profits are so large as to warrant us doing so. We have had to contend against infringements of our patents, and to defend what others have termed infringements, and we have been successful in every case. This gives us some encouragement, and it is gratifying to know it. During the year a branch has been opened in Paris in one of the most spacious streets, and already this has become a source of profit, although it was not opened until August, and we have every reason to believe the business there will be as productive as it is at home. We have also opened an establishment at Nice. I trust that in another year we shall be able to show you a much larger profit and increase of business.

Mr. Gifford, in seconding the motion for the adoption of the report, thought that the business had gone on even better than they might have expected. The Company had been doing better work, and although possibly the dividend was not so large as the directors might wish, it must be remembered that the opening of the Paris and Nice branches absorbed a certain amount of money inseparable from establishing new agencies, and was equivalent to putting some of the profit into capital.

Mr. Barbrook: Do you think the patents are as valuable now as they were? I find that in England you have taken out sixteen patents, four of which were taken out in 1884 and four in 1885, the last two being taken out in 1890. As a patent only lasts fourteen years, I do not see how some of them can be as valuable as they were, and I think something ought to be written off.

The Chairman: Since the report has been prepared, new patents, not only for England, but abroad, have been taken out, which we deem of even greater value than those which we already possess; therefore it will be seen that the directors are endeavouring to protect the Company in every possible way.

The motion was then carried.

A resolution, moved by Mr. Verden, recommending a dividend of ten per cent. on the Preference shares, was then carried; and a similar one, moved by Mr. A. Pringle, seconded by Mr. G. Davison, declaring a dividend of seven per cent. on the Ordinary shares, was also adopted.

Mr. Jay then moved the re-election of Mr. George Davison and Mr. Strong, the retiring directors. He was sure the shareholders would adopt the resolution with great pleasure, for the Company had been so well managed from the first that he would be very sorry to see any change in the directorate.

Mr. J. Spiller seconded. From the long personal knowledge he had had of Mr. Davison in connexion with photographic matters he knew how thoroughly his heart was in the work. He felt quite sure that Mr. Davison would do his utmost to bring the Eastman Company to a successful conclusion. Mr. Strong, he believed was the American representative on the board, and he (Mr. Spiller) ventured to congratulate the Company upon having so powerful a connecting link between the English and American companies.

The motion was carried, and Mr. Walker (Managing Director) moved, and Mr. Gifford seconded, the re-election of the Auditors, which also was adopted.

A shareholder inquired whether there was any probability of the interest being paid half-yearly.

The Chairman: In view of the large extensions in the way of building which the Company had undertaken, it was found necessary to retain funds in hand, but the matter will be taken into consideration in future by the board, and, if possible, acceded to.

A vote of thanks to the Chairman terminated the proceedings.

—*Financial World.*

CAMERA CLUB CONFERENCE.

The 1892 Conference will be held in the theatre of the Society of Arts on Tuesday and Wednesday, March 22 and 23, under the presidency of Captain W. de W. Abney, C.B., D.C.L., R.E., F.R.S.

The following programme has been arranged:—Tuesday, March 22, Conference at the Society of Arts, 18, John-street, Adelphi, to be opened by the President at 3 p.m. Papers to be read from 3 p.m. to 6 p.m. in the theatre:—

Opening by the President.

Mr. C. H. Bothamley, *Some Points in Connexion with Development.*

Mr. Leon Warnerke, *On Chemigraphic Etching.*

Mr. A. Pringle, *Photography applied to Medical Research.*

Mr. W. Willis, *Recent Improvements in Platinotype.*

Renewal of Conference at 8 p.m.

Symposium on Artificial Lighting in Photography.

Mr. Van der Weyde, *Demonstration of Use of Electric Light for Portrait Effects.*

Mr. E. J. Humphrey, *Oxymagnesium Lamps for Printing and Lighting.*

Mr. H. E. Armstrong, F.R.S., *Theory of Development.*

Wednesday, March 23, 3 p.m., Renewal of Conference in the theatre Society of Arts. Papers to be read from 3 p.m. to 6 p.m.:—

Mr. Henry Blackburn (editor of *Academy Notes*), *The Debt of Art to Photography.*

Mr. H. Stannus, F.R.I.B.A., *The Uses of Photography to the Decorative Artist.*

Mr. H. P. Robinson, *Paradoxes of Art, Science, and Photography.*

Captain Abney, *Some Uses of Celluloid Films.*

At 7.30 p.m. the annual Club dinner for members and friends will take place at the Monico Restaurant.

On Thursday, March 24, at 8 p.m., there will be an exhibition of lantern slides in the theatre.

All photographers are invited to take part in the Conference.

Our Editorial Table.

Kallitype, No. 2.

From the Birmingham Photographic Company we have received some specimens of kallitype printing No. 2, which illustrate in a favourable degree the varied capabilities of this beautiful process. The albumen like gloss on some of the pictures certainly conduces to the provision of the finer details, while the matt surface on others is as near an approach to the characteristic beauty of platinum as could be obtained. We welcome kallitype as a distinct and agreeable advance in silver printing.

To the professional photographer, the trade price list of Messrs. J. Martin & Co., of New Southgate, should be of direct interest. The "business memoranda" it gives are quite an education in the economics of enlarging, and the list also contains prices of the various kinds of work which Messrs. Martin undertake for the trade. We note with pleasure that Messrs. Martin & Co. have a ceramic department. Accompanying the list is a photograph of some ice crystals deposited in a porcelain dish last Christmas, exhibiting a wonderfully beautiful floral design. The picture has been seen by Professors Huxley and Tyndall, Mr. Ruskin, Mr. Glaisher, and Mr. Symons, who all express admiration of it.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

February 25,—Mr. W. H. Harrison in the chair.

Messrs. W. T. Coventon and J. Lillie Mitchell were unanimously elected members of the Association.

Mr. P. Everitt read the report of the Association's delegate on the Photographic Society's Affiliation Committee, and some discussion ensued as to the uncertainty of the financial position of that Committee.

A question premised that, by putting the lenses of a half-plate doublet of six inches focus close together, the objective became a whole-plate wide angle, and it was required to know whether the lens would then cover as well with the same stop?

Mr. W. E. Debenham said that in no case would a lens with the same stop cover equally for illumination or definition a whole plate and a half plate.

Mr. Everitt asked whether a more equal illumination could be obtained by a doublet with a short tube than with a long tube?

Mr. Debenham replied that the better illumination would be obtained with a short tube, because with a long tube, by putting the eye to where the plate would be, and looking through the stop, the whole of the surface of the stop is

not seen through, and the illumination with the longer tube must therefore be unequal.

Another querist desired to know if, in photographing an object with perpendicular lines, the camera was tilted to an angle of twenty degrees, at what angle must the camera be put to correct the distortion?

Mr. TEAPE mentioned that Mr. Chapman Jones had said, to obtain perpendicularity in such a case, the negative would have to be placed at an angle of thirty-one degrees.

After some slight discussion, the subject dropped on the understanding that it was to be dealt with in a paper by Mr. W. E. Debenham at a future date.

Mr. A. HADDON said that it would be within the recollection of members, that a strip of discoloured paper, from the margin of an Alpha print in the 1887 ALMANAC had, at a former meeting, been handed to him to test. He had submitted it to some experienced chemists, and had asked them to tell him what it contained. They had tested it, first by means of dilute hydrochloric acid and ferrocyanide of potassium, which produced a most distinct blue stain on both sides of the paper. All papers contained a certain amount of iron, and it was difficult to say whether that strip of paper contained more iron than was in it originally or not. But iron was in the strip when tested, and the colour in the paper was discharged by hydrochloric acid. If the stain were due to sulphide of silver it would not easily have been discharged by hydrochloric acid. Part of the strip was then tested for the presence of silver by boiling it in strong nitric acid. The addition of dilute hydrochloric acid to that solution produced a feeble cloudiness which was chloride of silver. His conclusion was that the print did not receive as much washing as it should have had, both iron and silver being left in. Either silver hyposulphite or a certain amount of the sensitive salt undissolved by the hypo must have been left in the paper.

After a short further discussion the meeting concluded.

Camera Club.—February 25.—Mr. J. B. B. Wellington exhibited his series of slides illustrating a *Tour in Norway*. Captain Abney occupied the chair.—After Mr. Wellington's lecture a miscellaneous set of fine lantern pictures by the same gentleman followed, and other slides were shown by Messrs. Urquhart, Hansard, Barton, and Scott. On March 10 a paper entitled *The Photographic Expression of Thought* will be read by Mr. A. Horsley Hinton.

Hackney Photographic Society.—February 25, Mr. Augustus W. Wilson in the chair.—The SECRETARY announced that several new books had been added to the library. A member asked for a good developer. Mr. HUTSON gave the following:—A. Hot water, 2 ounces; sulphite of soda, 4 ounces; sulphite of soda, 480 grains; ammol, 240 grains; water, to 20 ounces. B. Hot water, 20 ounces; carbonate of potash, 2 ounces; carbonate of soda, 2 ounces; water, to 20 ounces. For instantaneous work, 1 ounce A, 1 ounce B, and 3 ounces water. Landscape work, 1 ounce A, 2 ounces B, 4 ounces water. A question was asked whether the surveyor of a district would have any voice in the erection of a studio. Mr. CAPEL said he would not if 9 feet from highway and 15 feet from adjoining property. He said that if four small wheels were put on the question, it would obviate any difficulty in the matter. The CHAIRMAN then introduced Mr. A. L. Henderson, and prefaced the introduction by passing a high encomium on Mr. Henderson for his work in years past. Mr. HENDERSON gave an excellent lantern lecture on the Riviera, illustrating the subject with some capital slides, many being of a panoramic nature. Some two hundred slides were put through by the Hon. Secretary in response to Mr. Henderson's "Pass on, please."

West London Photographic Society.—February 26, the President in the chair, Lantern Evening.—Slides shown by Messrs. Lewis, Kellow, Hilton, Lewis, Hodges, H. [illegible], Secretary, [illegible], Hilliard, Whitear, and J. D. Rowland. Mr. England exhibited slide by slide, celluloid and glass slides, to show the difficulty of distinguishing one from the other, and explained that the celluloid slides were mounted in Mr. Scanlan's metal film-holder.

Putney Photographic Society.—February 27, Rev. L. Macdonald in the chair.—A short paper on *Exposure* was read by Dr. J. F. FARRAR, who confined his remarks mainly to the principles of light, its effect upon the dry plate, and the remarkable investigations of Messrs. Hurter & Driffield, illustrating the conclusions of these gentlemen by numerous carefully prepared tables. The Decoudun & Wathin exposure meters, and Messrs. Hurter & Driffield's actinograph, kindly supplied by Messrs. Marion, were exhibited and explained. The spectrum was thrown upon the screen by means of a bisulphide of carbon prism and attachments, lent by Messrs. Taylor, Taylor, & Hobson, to whose courtesy the Society is again indebted. There was a capital attendance, the presence of an unusual number of ladies being noteworthy. Mr. Rodney Few was elected a member.

Richmond Camera Club.—February 26, Mr. Cembrano in the chair.—The delegates (Messrs. Cembrano and Ramsay) appointed in connexion with the Photographic Society of Great Britain Affiliation Scheme reported what had occurred at the meeting on the 15th ult. Sample packets of their new rapid bromide paper having been forwarded by the Eastman Company, and distributed amongst the members at a previous meeting, Mr. Davis showed some results he had obtained with it, comprising a contact print (three seconds' exposure at twelve inches from gas flame) and an enlargement of a minute portion of the same negative to half-plate size, about nine and a half diameters. An alteration in the programme was made by the substitution for the subject announced (*Finishing in Monochrome*) of a demonstration by Messrs. Hill of their invention, "Cremo Fylma." The properties and capabilities of the sensitive solution were very clearly explained by Mr. Hill, jun., and his brother then proceeded to carry out a series of experiments, while specimens of the work, showing films positive and negative, enlarged and transferred to paper, opal, glass, &c., were handed round. The experiments were completely successful and the process was much admired for its simplicity and the apparent certainty in the results.

Croydon Microscopical and Natural History Club (Photographic Section).—February 26, Lantern Night, Mr. Edward Lovett (President) in the chair.—The Incandescent Gas Light Company demonstrated the use of their light as adapted to the optical lantern. One hundred and fifty slides, the work of members, was passed through the lantern during the evening.

West Kent Amateur Photographic Society.—February 24, Mr. John Taylor in the chair.—Mr. CLARK gave a demonstration with his Optimus enlarging apparatus, using a nine-inch condenser and a three-wick lamp, making several successful enlargements from half-plate to 12×10.

Bath Photographic Society.—February 24, third annual general meeting, Mr. Austin J. King in the chair.—Mr. P. BRAHAM said he understood Mr. Pumphrey did not seek re-election as President. He was sure they all valued Mr. Pumphrey's services highly. He now had the honour to propose Mr. Austin J. King as the future President. They had ample testimony of his fitness, of his ability as a photographer, and his congeniality. The motion was carried by acclamation. The PRESIDENT said he took the chair with reluctance, feeling that it was impossible to fill it as satisfactorily to the Society as it had been by his good and esteemed friend, Mr. Pumphrey. It was often a question in photographic circles whether a President should be an amateur or a professional. In Mr. Pumphrey they were able to combine the two. He had long been a professional, but of recent years he was an amateur—indeed an enthusiast. Following such a President, it was very difficult for any one to fill the office satisfactorily; he therefore moved: "That the hearty thanks of the Association be accorded to Mr. Pumphrey for the great energy and ability which he has displayed during his period of office as President, his many services to the Association, and acts of kindness to its members, and for the zeal which he has manifested in the progress of the art and science of photography." This motion was seconded by Mr. E. J. APPLEBY and carried by acclamation. The HON. SECRETARY then read the report and balance-sheet, which were adopted. Mr. P. Braham was elected to fill the office of Vice-President for the year. The following gentlemen were elected the Committee: Messrs. E. J. Appleby, A. F. Perren, G. F. Powell, W. Pumphrey (permanent member), Rev. E. A. Purvis, Canon Williams, and D. Williams; and Mr. W. Middleton Ashman, Hon. Secretary and Treasurer. Dr. PRESTON KING read a short paper on the subject of *Rudge's Biophantascope*. The biophantascope is an adjunct to the ordinary magic lantern, by means of which the animal depicted on the screen can be made to move with life-like accuracy. In the machine shown there are a number of photographs on glass of a man's face, taken under different conditions. In one the face is at rest, in another it is smiling, in a third frowning; in others the tongue protruding, or the eyes alone that move, so throughout the whole series. It is by throwing the light of the lantern alternately through first one and then another of these various photographs, making each image fall upon the same portion of the screen as the preceding one, and without any intermediate loss of light, that the life-like movement of the portrait is obtained. The speaker then dealt with the mechanical details of construction, after which the utility of the instrument was practically demonstrated by Mr. Rudge, who invented it. In the discussion which followed Mr. BRAHAM pointed out that an instrument constructed to register as perfectly as this one was a very difficult mechanical achievement, the smallest deviation in the positions of the negatives would be painfully apparent when enlarged. He thought Mr. Rudge had made a distinct step in advance by photographing the subject with the same arrangement used for projection.

Brighton Photographic Society.—February 23, Special Meeting, Mr Slingsby Roberts in the chair.—Mr. CAVEAT proposed that the members be asked to contribute towards a fund to pay off the financial deficiency. The resolution was agreed to unanimously. Mr. FOXALL then moved, "That this Society, known as the Brighton Photographic Society, be dissolved, such dissolution to take effect immediately upon the settlement of the liabilities of the Society." He did so principally to test whether there was sufficient life and animation in the Society to warrant them in carrying it on. He was at a loss to account for the unsatisfactory state of the Society, but there it was, and it had to be dealt with. If those present decided, under the circumstances, to continue the Society, he would do what he could to make it a success, but if, as he feared, there was not sufficient vitality in the Society, the best thing they could do would be to dissolve it. The CHAIRMAN proposed as an amendment that the words, "to have effect immediately upon the settlement of the liabilities of the Society," be omitted from the resolution. He thought they must have finality in the matter. It seemed to him that, if they postponed the dissolution of the Society to an unknown time, they would do no more good that night than they did at their recent annual meeting. He had felt a great deal of interest in the Society, and had done what he could to promote it, but there was no doubt about it, they were living, as it were, from hand to mouth. The deficiency would probably be as large, if not larger, a year hence. The meetings were not attended as they deserved. In the event of the dissolution taking place, though they would cease to meet as a Society, there was no reason why they should not meet in another form—namely, under the wing of the Natural History Society. He had been in communication with the Secretary, and had received a letter from him to the effect that the Council of the Natural History Society intended to institute a photographic section, and cordially invited members of their own Society to join it. The Natural History Society was an established institution in the town, and it struck him that, as a photographic section of it, they would take a far better stand than as a Society trying to run alone. Mr. HARRICANTLE seconded, but the amendment was lost, and Mr. Foxall's motion was then agreed to. At the adjourned annual meeting, which immediately followed, a Sub-committee was appointed to wind up the Society in accordance with the terms of Mr. Foxall's resolution.

Liverpool Amateur Photographic Association.—February 25, the President (Mr. William Tomkinson) in the chair.—Ten new members were elected. The PRESIDENT made a statement with reference to the new club rooms, and asked for suggestions regarding excursions during the coming season. Mr. FRED CLIBBORN then gave his new lecture, entitled *Two in Touraine*, illustrated by slides made by Mr. G. E. Thompson from photographs taken by him during a recent tour of the two gentlemen in France. The lecture was delivered in Mr. Clibborn's well-known racy style, which, whilst conveying valuable and interesting information, keeps the audience constantly amused by his exhaust-

less fund of dry humour. The photographs, which embraced views of the principal châteaus and churches of France, were all of that high order and pleasing variety of tone for which Mr. Thompson is noted.

Newcastle-on-Tyne and Northern Counties' Photographic Association.—February 25, the President (Mr. A. S. Stevenson, J.P.) in the chair.—Special Meeting to discuss and note upon the scheme proposed by the New Premises Sub-committee.—The scheme, which since last meeting has undergone some modifications, was recommended by the Council, and, on the motion of the Chairman, was carried enthusiastically. Mr. C. E. Borkas, the lessee of the Art Gallery, is to provide a commodious room for weekly or fortnightly meetings, and two or more dark rooms, with all conveniences, and to allow the Association the use of the Lecture Theatre for lantern shows, &c. The necessary alterations will be completed in September, when the Association will then enter into possession, and on January 1, 1893, the annual subscription will be raised to ten shillings and sixpence, and the entrance fee abolished.

Rotherham Photographic Society.—The third Annual Exhibition of the members of this Society was held on Tuesday and Wednesday in last week. The year's work, as shown by the 360 prints on the walls, revealed considerable technical progress, while, from an art standpoint, there had been some little advance made. Very excellent results were displayed, principally on bromide and albumenised paper. The chloride paper seemed to be gaining ground, while alpha and the ferro-prussiate methods had their followers. So far, none of the members appear to have taken up platinotype printing. Landscapes were very largely in evidence, while architecture (interior and exterior) was not extensively represented. There were practically no portraits or enlargements, and only one floral study. The exhibitors were Dr. Baldwin (President), Mr. E. Isle Hubbard, Mr. W. H. Haywood, Mr. G. T. M. Rackstraw (Vice-Presidents), Mr. H. C. Hemmingway (Hon. Secretary), Mr. J. Leadbeater (Treasurer), Mr. W. Mason, Mr. W. H. Shephard, Mr. J. W. Whittington, Mr. J. Caseldine, Mr. T. W. Mosby, Mr. F. W. Barwick, Mr. John Clarke, and Mr. J. Sykes. Hand-camera work, which, by the way, seems to be becoming a feature of the Society's efforts, was shown by Mr. Rackstraw, Mr. Hemmingway, and Mr. Clarke. The Sheffield Photographic Society, which has always shown a warm interest in the welfare of its near neighbour, lent several exhibits. There were some choice platinotypes by Mr. Ernest Beck (prize medallist); Mr. T. G. Hibbert had on view several sea pieces and landscapes, in which some particularly fine cloud effects were noticeable; and Mr. Crowther had sent a number of picturesque examples. Mr. A. H. D. Acland, M.P. for Rotherham Division, had forwarded half-a-dozen framed photographs of small size, but of much merit. Mr. Acland was a member of the Photographic Society, Christ Church, Oxford. There was a fairly large collection of choice reproductions contributed by the Autotype Company. Other exhibitors were the Eastman Materials Company, London; the Fry Manufacturing Company, London; Messrs. Elliott & Son, Barnett; the Britannia Company, Ilford; Mr. J. Crosby, Rotherham; and Mr. J. Leadbeater, Rotherham. Miss Crossley, of Maltby, as an amateur, sent several whole-plate prints pleasingly executed. The portrait work of Mr. Crosby was much admired, as were also the fine examples from the other firms named. Mr. Leadbeater's photo-micrographs were a source of a good deal of interest. During each evening there was a musical programme. There was also a short lantern entertainment in charge of Mr. Leadbeater, the chief slides being a series lent by the Fry Manufacturing Company, from slides made from negatives of the late Mr. Rejlander.

Shropshire Camera Club.—February 24, Annual Lantern Entertainment.—The exhibition opened with slides representing portraits, prepared from photographs, of the Mayor and Mayoress, by Mr. Naunton, followed by a selection, lent by Messrs. Valentine and the Woodburytype Company, illustrating scenes in Jamaica, Switzerland, Venice, &c., continued by a series by Mr. F. P. Cembrano, consisting of very fine examples of Moorish architecture, together with charming scenes of the Alhambra, which may be considered almost unique. Exhibition of members' work concluded the proceedings.

Tyneside Camera Club.—February 23.—The slides of the *Yosemite Valley* (by the California Camera Club) were shown before a large company of members and friends. Mr. Thomas Simpson read the lecture that accompanied the slides.

Edinburgh Photographic Society.—February 24, Second Popular Meeting.—The lantern slides shown were the selected works of the members, and principally those taken during the preceding year. Prominent among these were the three medalled pictures of the recent exhibition of the members' work for the past season. Perhaps a running commentary on the artistic qualities of the pictures would have been an added advantage to the simple titles and names of the exhibitors, but that is always delicate ground to deal with before so numerous an audience. The musical arrangements and the management of the lantern by Mr. Haddow were carried through with great perfection. The only fault, if it be one, was that the time occupied was too extended. There was a collection at the door in aid of the Dr. Maddox Fund.

Leith Amateur Photographic Association.—February 22, Lantern Night, Mr. W. A. Bill presided.—The lantern was managed by Mr. Berrie, and, in addition, musical accompaniments, vocal and instrumental, with a humorous lecture by Mr. Hunter, varied the programme. Upwards of one hundred and sixty slides were shown. They comprised, among the number, several copies of engravings, a class of subject which ought not to be seen at a photographic society's meeting. The great majority were of a high class of merit. The most prolific among the exhibitors were Messrs. Ewark, with twenty-eight; F. L. Lorimer, with twenty-one; and the Hon. Secretary (Mr. A. Pitkiethly), with thirty-two. As a proof of the activity of this numerically small Society, the whole number of whose members are under fifty, this meeting, showing examples of the works of seventeen of them, may be taken as an example by others of a more pretentious nature.

LANTERN SOCIETY.—March 14, Exhibition of Slides, for members and their friends.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

PERMANENCY OF PRINTS.

To the EDITOR.

SIR,—I am glad to have narrowed the issue down within its proper channel, and to have elicited Mr. Coles' opinions. For my own part, I can only repeat what I have previously said, that the balance of evidence is distinctly in favour of the permanency of gelatino-chloride paper, and, as long as this is so, I must be excused if I decline to hold different opinions. I would also say that I have never—either in writing or speaking—made use of any opinion of the experts above mentioned without quoting their "actual words." On the principle that "one swallow does not make a summer," I do not see the use of the test that Mr. Coles proposes. I will leave the matter in the hands of the future.—I am, yours, &c.,

JOHN HOWSON.

The Britannia Works Company, Ilford, London, E.

CUTTING PRICES.

To the EDITOR.

SIR,—A great deal has been said and written at one time and another about *cutting prices* and the injury that low-class photographers do themselves and the profession generally by making such ridiculously low charges, and turning out wretchedly bad work, which has the effect of bringing photography into evil repute amongst many persons residing in the neighbourhood of the *cutting man*; but, for downright absurdity (not to put too fine a point upon it) I never met with a case to equal that of a man trading near here, whose so-called "complimentary coupon" I enclose, and these coupons, circulated by thousands, have a villainous caricature of some unfortunate male or female pasted in one corner, and sets forth that our worthy brother professional is prepared to supply the public at the following rates, viz.,

	s.	d.
1 cabinet or 3 cartes for	1	0
3 cabinets or 1 cabinet and 6 cartes for	2	0
12 cartes	2	6
1 cabinet and 12 cartes	3	0

Now, how in all conscience is it possible for that man to do justice to his customers and himself, to say nothing of those who are endeavouring to get a fair share of public support, giving fair work for a fair price? No, the idea of forcing trade by such tactics is a false one, and only tends to spoil some who would pay the average charge for a good photograph without a murmur—they get instead a lot of rubbish, which, having paid for they don't like to throw away, and are ashamed to give to friends.

It would, in my humble opinton, be far better for our complimentary friend to do less work in a better manner, and get more profit; he would probably satisfy his clients and get repeat orders and would soon find that such a trashy way of making up business is a delusion and a snare. I venture to think, sir, that you will strongly condemn practices calculated to lower the standing of the professional photographers, and I know your words have the weight and influence born of experience and sound judgment.—I am, yours, &c.,

OLD PYRO.

Tottenham.

[The specimens enclosed are undeserving the name of photographs. We are constantly condemning such tactics as our correspondent complains of.—ED.]

LOSS OF DENSITY IN FIXING.

To the EDITOR.

SIR,—In the last issue of THE BRITISH JOURNAL OF PHOTOGRAPHY you refer to the statement of Mr. Albert Levy anent the loss of density in the fixing bath, and deny the possibility of such a thing. But I think, from experience, you must be wrong. The plates with which I am most familiar are the Ilford, Barnet, and Paget. With the first-named, if, on taking it out of the hypo, I think it would have been better if it had been a little less dense, I generally leave it twelve or fourteen hours longer in the hypo, and this generally is sufficient. With the Barnet the same thing will occur, but in a lesser degree; but, as regards the Paget, the reduction is scarcely to be noted. But I have before now accidentally left a plate in the fixing three or four days, and, when taken out, there has been little else but the ghost of an image. I judge, therefore, that a normal solution of hypo will dissolve the silver image. Try an Ilford plate, and prove it.

That funny paragraph *re* "Lynn Camera Club" is good, but I know of a certain amateur photographic club where, if the man don't turn up who is to read a paper or give a demonstration, the Chairman suggests penny Nap, which the assembled members receive with acclamation, and the evening is devoted to the charms of the spotted pasteboards. I think the members go home after such a night quite as edified and pleased as if photography had been on the *tapis*. Will you be good enough to hand

the enclosed (postal order 10s. 6d.) toward the Maddox Fund?—I am, yours, &c., C. H. EVANS.

Gainsborough Studio, Swansea, February 29, 1892.

[Our correspondent misapprehends the point of our remarks. We simply questioned the probability of any diminution of density taking place in a normal fixing bath used for a normal time. Immersion of a negative in hypo for "twelve or fourteen hours," or "three or four days," is, to say the least of it, rather a drastic and abnormal experiment which does not disprove anything that we alleged. As for the first part of the second paragraph of our friend's letter what can we say, but *O tempora, O mores!* We have forwarded the contribution.—ED.]

FADING OF THE LATENT IMAGE.

To the EDITOR.

SIR,—Some weeks ago you had a leader about the fading of latent image in bromide prints undeveloped. I am now able to assert that such fading does take place, that it occurs within a few weeks, and, finally, that longer delay does not increase the fading. Seven years ago, wishing to have copies from a number of negatives, I got some packets of bromide paper, tested my exposure, and the following day exposed two dozen. When I came to develop, I found I had made a blunder as to distance, and that all were hopelessly over-exposed for normal development. I laid the packet aside, and forgot about them until the other day. I now found them so under-exposed, that half an hour of a normal developer was required to bring them up. The paper remains as sensitive as ever, and, when I exposed half of one of the sheets under a fresh negative, it developed in the usual time free from appreciable trace of the original picture, which came up very slowly on the other half of the undivided paper. A month ago I had occasion to take a dozen bromide prints from one negative. Having got the correct exposure, I did the whole dozen, each with two-thirds of an inch of magnesium ribbon at a measured distance of three feet. Six of the sheets I developed, and got excellent prints. The others I tried last night, developer and temperature being identical, and had a repetition of my former experience. I enclose a sheet showing the two prints of the latter experiments.—I am, yours, &c.,

February 25, 1892. BAILEY HEATH.

URANIUM-TONED BROMIDES.

To the EDITOR.

SIR,—It has often been remarked that the colour imparted to bromide by uranium is easily washed out with ordinary water, and can, from my own experience, be rapidly and entirely destroyed by adding a few drops of ammonia, or a little soda, to the washing water. Now, could a question not arise that, as the colour is fugitive under such simple treatment, a doubt as to its absolute permanence is reasonable? A mountant containing any trace of an alkali would cause irretrievable damage, and an atmosphere with traces of ammonia vapour perhaps be ruin. I think it is worth consideration.

I note that Mr. J. Weir Brown says Mr. Levy suggested that the ferricyanide of potassium combined with the silver image, and forms a ferrocyanide of silver, with which the uranium nitrate enters into combination. If this is the case, does the after-treatment with ammonia reconvert it, or what is the action?

I may remark that the ease with which ammonia will reduce the colour can be taken advantage of in treating negatives where local reduction is requisite, by very slightly intensifying the whole image, and subsequently rubbing the part with a stump or other suitable appliance, moistened with a dilute solution of ammonia. I have found this more expeditious and certain than with Farmer's reducer.—I am, yours, &c.,

Glasgow, March 1, 1892. ALEC. J. JONES.

DARK ROOM AT RIGI-SCHEIDEGG.

To the EDITOR.

SIR,—It may be perhaps of some interest for your readers to know that from June 15 next they will find at Rigi-Scheidegg a nice small laboratory for photographic work, and open to visitors.—I am, yours, &c.,

Lucerne, February 25, 1892. D. R. SCHERLER-HAUSER.

INSTITUTE OF PHOTOGRAPHY.

To the EDITOR.

SIR,—I sincerely hope that the efforts of Messrs. Bolas, Meldola, and Warnerke, together with your own powerful leader of the 12th instant, will result in the commencement of a Technological Institute, if only on a modest and unpretentious scale. Is anything more likely to command the support of all intelligent photographers than the establishment of an institute for the purposes you name, and also, I hope, without encroaching on any one else's preserves, of a central club, to which could be attracted all the men of "light and leading" in the practice of photography.

It should not be difficult to get, in a matter of so much importance, the co-operation of the local societies; and, as bearing somewhat on the subject, I would like to interpose my own personal experience. Six years ago, being at the time connected with a well-known society, I advocated, in committee, the formation of classes for the study of theoretical photography, the crude idea being to work on the syllabus of the City and Guilds of London Institute, and for the society to give to any successful student certificates signifying competency not only for theory, but, after contributions of work in open exhibitions, for practical work. I considered that such certificates could not fail to be of value to the possessor, although possibly the field of study would have been somewhat limited. The project fell through, but from one cause only, which was, however, a very important one—viz., the want of a qualified (by City and Guilds of London Institute) teacher. There was otherwise, I think I may say, no objection whatever to the scheme. I never gave up entirely the idea; but when, a few years later, I found myself (after passing the necessary examinations) in a position to offer my own services, circumstances removed me from the town. If it had not been for that removal, I should certainly have endeavoured to make a beginning. Let me say here, that if, in my present position, I can do anything in the direction indicated, I shall certainly be ready to help, but there should be concerted action.

I would suggest the formation of a "British Photographic Institute," subscription one guinea for London members, half a guinea for country members, with the usual offices; and an educational and research committee to be formed of men of such calibre as Captain Abney, and others, whose names naturally present themselves in a case of this kind, who would formulate a syllabus of study for the guidance of provincial teachers; examinations to be held yearly, exhibitions of photographs, &c., also yearly, certificates then to be awarded with reference to competency. It would be strange, indeed, if throughout the country we did not find here and there a promising recruit for the research laboratory at headquarters.

Your suggestion, *re* the "art" side, is not to be overlooked. It would not do, for instance, to place this important branch in the hands of a man who, after laying down the canons and founding, may be, a school, is liable to turn tail, and generally to play the dence with our young and budding workers. On the whole, perhaps, it would be better to follow as much as possible the old masters until such times as the "new" men have discovered a better course.

Hoping that this proposal for the establishment of an institute will not be allowed to drop,—I am, yours, &c., D. D.

February 23, 1892.

A WORD IN SEASON.

To the EDITOR.

SIR,—The long-vexed question as to the right of photographers—professional and amateur—to call themselves "artists" is one of easy solution. By the right of custom they have a trade right to the distinction. Have we not "artists in hair," and "artists in boots?" Why not, then, artists in photographs?

The French, as a nation, are the most artistic people in the world (unless it be the Japanese). In France a painter calls himself a painter, never an "artist;" he leaves that to the artisan, and holds the term in small esteem. I am a painter, photographers may call themselves artists without offending my prejudices.

Would not all reasonable ends be served by people calling themselves what they really are? To wit, doctors, lawyers, authors, painters, photographers, &c., prefixing the qualifying "amateur" when not professional.

In respect to the question whether photographs are works of art, something may be said on both sides. That a photograph may possess much artistic merit, no cultivated mind could doubt. That the best photograph that ever was, or ever could be, made could have the same art qualities which characterise the works of the world's renowned painters, no sane mind could assert.

To try to force upon the improving art perception of the present generation any fad-photographs as works of high artistic merit is vain and ridiculous. The most rampant of professors who tried this ended ignominiously in "a renunciation." On the other hand, all that is artistic, all that is good and true in a photograph, will earn instant recognition and retain admiration.

Processes and materials are something, but the man who uses them gives to his work all the art quality it possesses. With a natural artistic temperament and feeling a man may produce photographs of great artistic merit. A painter needs, and must possess, in addition to these natural endowments, an executive skill of a kind which only years of devotional study can give, and imagination, with which it yet remains for science to discover a means to give to the camera.—I am, yours, &c.,

Bloomsbury Square, W.C., February 22, 1892. BART ROUS.

Exchange Column.

Answers to Correspondents.

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

John Thomas Barker, Stourbridge.—*One photograph, Snow scene, Vine Inn and Flour Mill. Two photographs, Snow scene, Adam's Hill, Clent, Stourbridge. One photograph, Snow scene, St. Kenelm's Church, Clent, Stourbridge.*

NEGATIVE.—Copy the photograph, and from the transparency make another negative.

J. CRAWFORD.—We know nothing more of the matter than that which appeared in the paragraph to which you refer.

A. F.—The Sciopticon Company, of Colebrook-row, N., who are the makers of the camera, will give you all particulars.

O. B.—1. The silver nitrate is largely in excess. 2. The old methylated spirit is not now retailed in such small quantities as you require.

H. W.—1. The pictures are excellent. 2. The stains may probably be removed by dilute nitric acid. 3. Preferably after the picture is printed.

W. MAJOR.—1. By a separate pneumatic tube, we should think. 2. The ventilator would answer the purpose. 3. Consult our advertising columns.

WELSH PHOTOGRAPHER.—For *cartes* and cabinets you had better continue to employ your portrait lenses. No other lenses are so suitable for that kind of work.

J. PEARSON.—Mr. Ackland is not a commercial maker of collodio-bromide plates, a modification of which process is simply named after him as the author.

J. C. P.—The material is celluloid. We do not know where it may be obtained in such thin sheets; probably Mr. J. R. Gotz, of Buckingham-street, can supply you with the necessary materials.

F. A. BRUTON.—Probably Mr. Common or Mr. Isaac Roberts, have numerous photographs of nebulæ, star clusters, &c.; but it is doubtful whether you could obtain them from them. They are not on sale anywhere, to our knowledge.

S. O. L. D.—Quite enough has been said with regard to the "pastel portrait" business, not only by us, but by almost every other journal. If you had only read what has often appeared in our columns, you need not have been victimised.

P. O'GORMAN.—The process of photographic engraving or etching (intaglio plates) attributed to or said to be Klic's process, is not patented; therefore, it may be worked without hindrance. Whether the process be that worked by Klic or not, it is one capable of yielding excellent results in experienced hands.

H. B. H.—1. Between the so-called sub-carbonate and pure carbonate of soda and the common washing salt there is little, if any, practical difference in development; but the hydrate (which is the caustic compound) is far more energetic. 2. Send us a letter addressed to the gentleman named, and we will forward it.

HIBERNIAN ISRAELITE (Bournemouth) asks what are the advantages, if any, of pebble spectacles over those made of ordinary glass?—In reply: Pebble glasses, owing to their hardness, retain their brilliance longer than ordinary glasses, and, being of a higher index of refraction than the latter, the radius of the curvature may be lengthened.

STAFFS. says for many months past he has been saving the old developing solution, and now he has a paraffin cask full of it, and asks the simplest method of recovering the silver from it. As the developer from dry plates contains no silver, there is none to recover. Hence the best plan of dealing with the solution is to run it down the drain.

B. A. (Cambs.)—The *Utrecht Psalter* has been reproduced photographically. The work was executed some few years back by the Autotype Company by the collotype process. We are not sure whether the reproduction was published by them, or by one of the societies. A letter to the Company, 74, New Oxford-street, will secure you the information desired.

T. STEDWELL.—It would be quite illegal to produce miniature bank notes for large, or indeed any, amounts by photography to be used as "Christmas cards." Whether the Bank authorities would interfere with such small reproductions as "an inch long," we cannot say. Our advice is, Write to the Governor of the Bank, and explain what you wish to do.

ALPHA.—If the paper is some of the first put upon the market it must now be tolerably old, and has possibly with age become somewhat deteriorated, particularly if it has been kept under adverse conditions. We recommend you to procure a small quantity of fresh, and then try the two kinds together. This will prove whether the paper is at fault or whether it is a question of manipulation.

F. H. J. RUEL (St. John, N.B.).—1. The Eastman Company, of Rochester, N.Y., have recently issued a camera known as their No. 4 Kodak, which is adapted for dark slides. The shutter is exceedingly rapid, but the lens is not equal in rapidity to Wray's 5 × 4, which works at *f*-5½. We are not aware of any one single hand camera in this country embodying all your requirements. 2. The system is excellent for the purpose.

W. H. GILDER (Baltimore).—The panoramic camera, of which you send sketches, is quite practicable, but it is almost identical in principle with that by Johnson & Harrison, which was brought out many years ago. It is, however, imperative that the camera be rotated from a point under the optical centre of the lens. The idea is undoubtedly a meritorious one, but we fear that there is at present little prospect of its commercial success on the English market.

J. P. MILNES.—1. A single landscape lens covering the size of plate used. 2. Consult our advertising columns. There are so many excellent instantaneous shutters on the market that we cannot give preference to any one—besides, it is against our rules.

BEXLEY HEATH.—There are several ways of producing what are known as "doubles." The plan we gave you in reply to your previous query, that of taking them direct in the camera, is the most general, because it is the most simple. It can, of course, also be done by double or triple printing from different negatives, but this method is more troublesome when a number of prints are required. The picture forwarded was not retained. Why not ask your friend who made it, and said he printed it from separate negatives, to tell you how he did it?

GEO. STEVENS says he has been experimenting in photo-lithography, and he finds a difficulty in applying the ink to the stone, and fears the roller may be at fault. He adds that he bought it second-hand, and wishes to know the condition the leather should be in, as his is very hard.—The leather of the roller should be soft, like leather well indurated with fatty matter. If it be as described, it is next to useless for the work. A great deal of the success in photo-lithography depends upon the proper condition of the ink roller. Better submit it to a working lithographer before wasting more time.

W. D. says: "Please to answer the following questions, and oblige, viz.—1. If a photographer wishes to prevent others from copying a photograph that he intends selling (portrait), what has he got to do and what does it cost? 2. If a photograph has the word 'copyright' on the mount, does that prevent one from copying it, or does it only do so for a certain time? 3. I have a card that says on mount 'Copyright reserved.' What does that mean?"—1. Register the picture at Stationers' Hall. The registration fee is one shilling. 2. If the word copyright appears on the mount, it infers that the picture has been made copyright. The copyright in a picture is for the life of the author and a certain period after his death. 3. We do not know the meaning of "copyright reserved" as here applied.

GEORGE GRANT writes, *re* copyright: "I would like you to give me your opinion on the following points. Not the morality, it's the law that is wanted. 1. Supposing I issued in January a photograph; somebody copied it, and I see them selling it at half-price. If I registered it on March 1, could I stop the sale of copies copied from these photographs issued in January? 2. Or could I derive any advantage by now registering the photograph?"—1. This is somewhat an open question. If we mistake not, contrary decisions have been given on this point. Perhaps some of our legal readers will express their opinion. 2. By registering the photograph now, protection would certainly be secured against piracy of any copies issued after the date of registration. Of that there is no doubt.

H. H. H. says: "Wishing to dry some negatives, the other day, in a hurry, I did as I had often done before, placed them in a dish of methylated spirit. Immediately after they were immersed the spirit became "milky," just as it would have done had "finish" been used. Thinking I had been supplied with this, I sent the remainer back; but the seller replied that it was spirit, and that it contained no gums. The negative dried opalescent, and not transparent as usual. Can you explain the cause, or has the dealer deceived me?"—The spirit used was no doubt free from gums, but, being according to the new Excise regulations, it becomes milky in the presence of the water contained in the negative. This is one of the inconveniences to photographers of the new regulation. We suppose, however, it must be put up with for the present.

THE PHOTOGRAPHIC CLUB.—March 9, *The Oxyhydrogen Microscope*, Mr. T. E. Freshwater, and *The Incandescent Light*. 16, *Shutters*, Mr. A. S. Newman.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—On Tuesday, March 8, a paper will be read on *Photography applied to the Detection of Crime* by Dr. P. Jeserich. The paper will be illustrated by lantern slides.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—March 10, *The Wet Collodion Process*, by W. E. Debenham. 17, Monthly Lantern Night. 24, *Continental Photographic Establishments and their Influence*, by W. H. Harrison.

MR. GUSTAV MULLINS, the Court photographer in the Isle of Wight, recently took the first portrait of Prince Donald of Battenberg, the youngest child of Prince and Princess Henry of Battenberg, at Osborne. The groups of the Royal tableaux at Osborne were taken on the stage. This is believed to be the first occasion on which Royalty has been photographed by flashlight.

ON Saturday, March 12, the members of the Holborn Camera Club hold their annual exhibition and *conversazione* at Anderton's Hotel. The following are the classes for competition by the members:—Class 1. For the best display of the most numerous and meritorious prints, the best average to be the basis of the judgment. 2. For best display of six pictures by new members since last exhibition. 3. For the best display of six pictures by old members of the Club who have started photography since the last exhibition. 4. Single portraiture, any size. 5. For the best set of six lantern slides. 6. Half-plate and 5 × 4, best set of six. 7. Quarter-plate, best set of six.

JOURNAL OF PHOTOGRAPHY.

No. 1662. Vol. XXXIX.—MARCH 11, 1892.

BINOCULAR EXAMINATION OF LANTERN SLIDES.

At the last meeting of the London and Provincial Association, a small piece of apparatus of the lanternoscope *genus* was exhibited, coupled with the name of Mr. George Mason, of Glasgow, as its sponsor.

Hitherto "lanternoscopes," by which we mean the pleasant and pretty little boxed-up table-stands for viewing lantern slides with a peep-hole in front containing a single magnifying glass through which to look at them, have been liable to the serious drawback implied in one eye only being available for the purpose; but in the one in question, the infinitely more comfortable and natural method of employing both eyes has been adopted. This is effected by the means we described so long ago as 1884, since which time till Mr. Mason took it up several months ago, it seems to have been lying *perdu*.

It was, as we said on the former occasion, a matter of regret that one could not examine a lantern slide under a certain degree of magnification with both eyes, as otherwise a very pleasant table instrument might result with which one could while away many an hour in looking at these attractive pictures, which would then be seen under conditions more favourable than, and with apparent dimensions quite as great as, when they are projected on a large screen for the benefit of the multitude, and when no time is afforded for studying any one or more special subjects in detail.

The remedy for the shortcomings of the single eyepiece of the lanternoscope is obviously to have two eyepieces. These must of necessity be prismatic in their nature—that is to say, the eyes must each look through the eyepiece lens under circumstances which, assuming a circular lens, shall cause decentering, or transmission to the eye through a portion of the lens at one side of its centre. This, as we have formerly shown, means really the utilisation of a prism, either with or without its surfaces being ground to a curve. In the former case a lens must also be employed; in the latter it is unnecessary.

If a *very* short focus of eyepiece be desired, it is essential that it be achromatic; but otherwise it is not necessary, as the slight bending of the rays required does not cause any appreciable colouration more than would a pair of short-focus spectacles decentered to suit vision correctly.

We have had a binocular prismatic lanternoscope made of only four-inch focus, the eyepieces being achromatic, and constructed on the principles we published six years since; but, except under very exceptional circumstances, we do not recommend the employment of such great magnifying power. By exceptional circumstances we mean placing an instrument of this nature in the hands of the public generally, on account of the possibility of its being unsuited for all kinds of vision. In Mr. Mason's new binocular, he has, at a small sacrifice of magnifying power, preferred to adapt it to the vision of the many, and therein he has acted wisely.

What is the best diaphanous material with which to form a backing for the lantern slide when viewed in this binocular diaphanoscope? Ground glass will answer, but it is far from being the best. If too close to the transparency, it causes a granular appearance that is unpleasant. Flashed opal is much to be preferred. We have, with excellent effect, employed glass coated with a thin emulsion of clarified gelatine and oxide of zinc, and pleasing effects may be readily obtained by bands of colour painted across a strip of glass at the back, by which can be imparted a blue tone to the sky, a grey to the middle distance, and a warm brown or green tint to the foreground.

In these few remarks we have employed the term lanternoscope for our own present convenience, as a descriptive word introduced by Mr. Tylar, of Birmingham, but without any desire to deprive him of its exclusive use, although as recent enactments show no protection is now given to the holder of any title or trade mark which can be shown to be of a descriptive nature—a finding with which we have no sympathy.

PHOTOGRAPHY AND THE DETECTION OF CRIME.

Dr. Jesserich, of Berlin, may congratulate himself upon having secured the enmity of several sections of the criminal classes. According to his paper, which was read at the meeting of the Photographic Society of Great Britain on Tuesday night, photo-micrography has enabled him to evolve a class of criminal evidence which a few years ago would have been deemed impossible to secure. The value of photographs of the scenes of crimes and accidents taken immediately after the occurrences has, however, long been recognised by others as well as Dr. Jesserich, but it has remained for him to apply photography to certain ends which, so far as we are aware, had not before been sought in legal procedure. His paper dealt with two sections of the subject, the first embracing photo-micrographic reproductions of substances not to be identified by other means; the second treating of the detection of documentary alterations and erasures by colour-sensitive photography.

Hairs found on the bodies of murdered persons, when photographed under microscopic magnification, have been proved to coincide exactly with the hairs of suspected persons, and in one case the hair of a dog was shown to have emanated from an animal which belonged to an accused person. This evidence was mainly instrumental in securing convictions. In like manner the hair of a victim was found to be identical with that taken from the clothing of a suspected person. Seen under microscopic magnification, the points of difference

between a man and a woman's hairs and the hairs of animals are very strongly marked.

Coming to the determination of human blood in contradistinction to the blood of mammalia, the doctor easily establishes the difference in the sizes and shapes of the corpuscules, by the same infallible means, the practical application of the proofs finding play in demonstrating that an axe, although wiped clean, had distinct traces of human blood upon it, which the accused asserted was the blood of a goat. By the same method a spot of blood on the clothes of another accused was also unerringly indentified, to the confusion of the suspected individual.

We should infer from Dr. Jeserich's complacency and exultation at the success of his evidence in bringing home guilt to accused persons—who, in many cases, obligingly confessed when confronted with these ingeniously conceived accusations—that German judges and juries dwell on a high level of scientific reason. We are not so sure that similar evidence if produced in a British Court of justice would so easily weigh down the balance one way or the other, inasmuch as that evidence is, after all, only more or less of a presumptive nature, and quite conceivably open to the admission of error.

In the discrimination of forged documents, Dr. Jeserich strikes us as having achieved results which preclude the possibility of exception. Ordinary photographs of altered writings quite fail to accentuate, or even indicate, alterations, whereas "colour-sensitive plates in a suitable light" (we quote the whole of the description of the process as given by the author, although it is obvious what is meant) not only lay bare such alterations, but also differentiate between variously coloured inks, and even distinguish the original writing from that superposed upon it. The value of photography in such cases as this, which was amply demonstrated by the slides shown on Tuesday night, seems to us to open up a gloomy prospect for so-called experts in writing.

Limited space constrains us on the present occasion to do no more than glance at the salient features of a most able paper, interesting, perhaps, rather as an account of what photography is capable of achieving in the field of strong presumptive evidence in doubtful cases, as well as in the detection of forgeries, than as an exposition of the process employed; but, with the hint thrown out by Dr. Jeserich, we have no doubt that British photo-microscopists and photographers will not long delay entering that field, for, especially in the detection of forgery, the assured penetration and fidelity of photography will be welcomed by the officers of justice and society at large.

THE EFFECTS OF MOISTURE IN CARBON TISSUE.

The reviving interest now being taken in carbon printing calls to mind an important point in connexion therewith that is often overlooked by some workers, and may still be unknown to novices. We allude to the amount of moisture present in the film. It is tolerably well understood that carbon tissue is insensitive to light when it is wet, and that, therefore, it can be sensitised in open daylight, as it only acquires sensitiveness as it becomes dry. But it does not, on the other hand, appear to be so generally known that the film is equally as insensitive when it is in a state of dryness. By dryness in this instance is meant complete desiccation. When the tissue is in this condition, it may be as safely exposed to daylight as when it is wet. Therefore it will be seen that, as the film is insensitive alike when dry and when wet, the hygroscopic condition of the bichromated gelatine is an important factor in carbon printing.

Want of knowledge of the above fact fully accounts for many of the failures met with by some who essayed carbon printing in former times, when they had to depend upon tissue of home sensitising, which was not always secured in a uniform condition as regards the moisture it contained. Hence there was frequently a considerable waste of material through errors in exposure. However, this may be considered a thing of the past, as the tissue can now be obtained commercially, either in large or small quantities, to suit consumers, ready sensitised and in the right condition for use, containing neither too much nor too little moisture.

It should, however, be kept in mind that gelatine, particularly when it contains saccharine matter, is an absorbent condition, and that, if it be exposed to a damp atmosphere, it will take up moisture, which may have a material influence upon its sensitiveness to light, especially if it be kept some little time before or after it is printed. This being the case, it is obvious also that attention should be paid to the conditions under which it is employed. For example, if the tissue be in its very best state, any alteration in its humidity, one way or the other, would be the reverse of improvement. For this reason, the paper should never be exposed unnecessarily to the atmosphere, the state of which, in this country, is continually varying. Again, if the tissue in its normal state be put into the printing frame, and backed up with damp pads, it will absorb moisture from them, and consequently become more sensitive, to say nothing of its "buckling," on account of its expansion. On the other hand, if the pads or surroundings be made abnormally dry, they will deprive the tissue of some of its humidity, and thus affect its sensitiveness.

Not only does the amount of moisture present in carbon tissue influence its sensitiveness, but it very materially affects its keeping qualities. The more humid it is, the shorter time it will retain its solubility and normal degree of sensitiveness. It is tolerably well known to most workers that, as insolubility increases, so does the tissue become more sensitive. The tissue now supplied commercially contains such an amount of moisture that, at this time of the year—for temperature is a factor in the case—it will, with proper care, keep for two or three weeks in good condition; but, if it be subjected to a humid atmosphere for a short time as soon as received, it would probably become quite unworkable at the end of a week, while before that time its sensitiveness will have become greatly enhanced.

Seeing that the presence of moisture in the paper has such a tendency to destroy its keeping qualities, it will naturally occur to some that, if it were made quite dry, it would retain its solubility for a longer period. This is the case; but, as mentioned above, a certain degree of humidity is necessary for successful working. A degree of dryness that would ensure better keeping qualities would considerably militate against sensitiveness and other essential qualities. It is a fact that carbon tissue, if it be thoroughly dried—by this is again meant completely desiccated—can be, and has been, kept good for six months and upwards. Probably it could be preserved almost indefinitely, without having its solubility destroyed. But in this condition it is quite unworkable, although it still retains its original properties if the proper amount of moisture be restored. This may be done by exposing it for a time to a damp atmosphere.

It might be suggested that carbon tissue could be supplied that would keep almost indefinitely, and have the moisture

introduced when it was required for use. So it could; but, unfortunately, practical difficulties step in the way. In the first place tissue, to possess this property, is in such a brittle condition that it cannot be bent without cracking. Then, there would be the difficulty of introducing the right proportion of moisture, and getting it evenly diffused through the entire thickness of the film. For it will be manifest, as the moisture is first absorbed on the outer surface, that that becomes moist before the inner portion is affected, and, if the exposure to damp were continued long enough for it to penetrate to the latter, the former would become too humid. This difficulty might, however, be overcome by permitting a certain amount of moisture to be taken up by the surface, and then storing the tissue sufficiently long for it to become diffused throughout. The thing has been tried, and it answered with experienced workers; but, in practice, it was found to involve more trouble, and required greater knowledge in getting the tissue in a satisfactory condition, than in sensitising it in the first instance, while the results, even in skilled hands, were less uniform. The effect of moisture in carbon printing may be recurred to on some future occasion.

PRINTING FROM DEFECTIVE NEGATIVES.

It is a very frequent occurrence to find it necessary to print from a negative that, in its natural state, is very far from giving a satisfactory result. The friendly advice, "Smash it, and take another," can rarely be followed in such cases, for the very reason that renders the task necessary—namely, that the negative, from one cause or another, cannot be replaced; and, on the same account, the risk attending any attempted dodging or patching of the precious negative itself is seldom faced.

The intensification of thin images, or the reduction of those that are too dense, are amongst the simplest and safest operations that may be required under such circumstances; yet even these are shirked, no doubt chiefly on the ground of the fatality that seems to hang around negatives that are unique. The intensification of a gelatine negative that has been made some time, and perhaps seen some use, and of whose antecedents little that is definite is known, is a different matter from taking in hand a plate that is fresh from the developer, and whose whole history is an open page. The reduction of the denser parts of an image in that way defective is even still more risky, whether the chemical or mechanical methods be adopted, for gelatine films behave very erratically sometimes under such treatment. After using the ferricyanide and hypo reducer, probably on some dozens of plates, without a single hitch, it was reserved for us to make the discovery of one of its peculiarities—its proclivity to yellow stain—on a rather valuable negative, that had done very well in its unreduced state, and which did not improve in the process. The plan of polishing with a tuft of cotton dipped in spirit is another plan that answers admirably in numerous cases, but has a most unhappy knack of breaking down when called on for a special effort.

Under the circumstances, it is not surprising that the methods which leave the original negative intact are those which find most favour. If the case is one simply of over or under-density, the plan is to be recommended in preference to that of reproducing it through the intermediary of a transparency, as it is well known that negatives that do not print satisfactorily on albumenised paper will very often give a really good result on a gelatine plate, or better still on carbon transparency tissue. This we always prefer when feasible.

Another method, and one which lends itself equally well to general or to merely local treatment is one that was first described by Mr. William Brooks some years ago, consisting in making a reproduced negative impression upon albumen paper, and attaching this to the back of the glass, so that its parts register with the negative film. Images that are generally too thin are admirably reinforced by this means, while, if portions of the negative only require modification, the remaining parts of the picture may be taken out by chemical means from the paper negative, or even cut out. The paper may be oiled in parts, and left in its original condition in others when necessary, and, finally, the surface of the paper serves admirably for retouching upon. One care should be taken—namely, that the paper negative be made to adhere to the glass by the edges only, as, if moistened and caused to adhere over the whole surface, it will expand irregularly, and the result will be a want of coincidence of the outlines.

Coating the back of the glass with coloured and semi-opaque varnishes, portions of which are scraped away when necessary, has found many supporters, and, in careful and skilful hands, is no doubt a useful method. But it undoubtedly requires this care and skill in order to ensure success. A plain matt varnish employed to form a tooth for the pencil is also useful, and is easier to work than the others.

Tissue paper and ground-glass screens fixed to the front of the printing frame, or even placed in contact with the back of the negative, are frequently of the greatest utility when local treatment is necessary; but, as already remarked, a considerable degree of care and skill are necessary in the execution of the work with brush or pencil that will be required in such cases. The trouble may, however, be greatly reduced if the plan be adopted that has been previously recommended for vignetting, of keeping the printing frame in motion during exposure, as then, owing to the slight space that exists between the negative and the mask, the effect of the pencil or brush marks is softened or vignetted, and made to harmonise more closely with the image proper. Such treatment is specially adapted, in portraiture, to negatives in which the facial gradations are too strongly marked and print heavily; if a sheet of tissue paper, or *papier minéral*, be strained over the reverse side of the negative, and the pencil applied pretty strongly over the lines or shadows that are too strongly rendered, these will be found, when printed on the rotating platform, to be wonderfully softened without, on the one hand, interfering with the definition of the negative, or, on the other, betraying the use of the pencil. Those who have tried it will know how difficult it is, without considerable experience, to tamper with the lines and shadows about the eyes of a portrait and still retain the expression, or perhaps even the likeness; but by the method given it becomes comparatively easy.

In a large majority of instances what is chiefly required is the modification of the general density of the negative without any special local treatment, and it is to such cases that our remarks are principally intended to refer. As already suggested, the reproduction of the negative by means of a dry plate or carbon tissue forms an almost invariably suitable way out of the difficulty, but it necessitates the double operation of making a transparency from which to reproduce the negative, and this is in many cases objectionable. The same remark applies to the Brooks' method, also alluded to in the earlier part of the article, which possesses the additional disadvantage of greatly increasing the time occupied in printing, owing to the want of transparency of the paper support of the auxiliary negative.

But there can be little doubt that for thin-plate negatives the system of supplementing the original image by the superposition of a second one, or, in the case of "hard" negatives, of a thin positive image, as recommended some years ago, is a thoroughly sound, if not the very best, one.

(To be concluded.)

Photographic Convention of the United Kingdom.—Although it is pretty generally known that the Convention this year takes place in Edinburgh, the time at which the meeting is fixed to be held is not so well known. We learn that the date has been fixed for the week commencing July 11. In order to be in time for the opening meeting on Monday evening, those who have to travel a considerable distance—from London, for example—will consult their convenience by leaving on the night previous, by which arrangement they will be able to arrive in Edinburgh in time for breakfast next morning.

Dallmeyer's Teleo-photo Lens.—We congratulate Mr. Dallmeyer upon having effected a genuine advance upon the original idea, which is now sufficiently familiar to our readers. We have long thought that a better back combination for a teleo-photo lens than the biconcave lens, whether single or achromatised, might be devised in order to overcome the lateral aberration consequent upon the employment of that form. By the symmetrical combination, each element of which is achromatic and concave *per se*, now adopted by Mr. Dallmeyer as a distributor, we believe that he has placed his teleo-photo lens on a substantial basis, and one by which a large field is capable of being sharply covered. The details of construction will be found on another page.

Photograph of the Moon.—In *Knowledge* for the current month there is an excellent photograph of the moon (taken about as it w entering its second quarter) from a negative taken by the Messrs. Henry. The plate was placed behind the eyepiece and the large picture then taken direct, being fifteen times larger than would have been the result if the plate had been placed in the ordinary manner in the focus of the objective.

Photography and the Behring's Sea Difficulty.—We note that photography has been used for official evidence in a novel manner. Our readers are away of the difficulties surrounding the seal-fishing in Behring's Sea question, and Sir G. Baden Powell lately paid a visit to the spot, and took a number of photographs, especially of those spots known as the Breeding Islands. The plates now developed show the presence of seals in hundreds of thousands.

Enlargement of Microscopic Objects.—Sir David Salomons recently gave a lecture on *Optical Projection*, a simile from which may be quoted. Speaking of the enlargement of microscopic objects, he brought before his audience a comparison which would bring home to the least mathematical mind among them a concrete idea of what a certain amount of enlargement, as expressed in the ordinary manner, really meant. He showed that a postage-stamp, for instance, if enlarged 4500 diameters, would cover two and a half acres!

Photographing on Wood.—At the last meeting of the London and Provincial Photographic Association, Mr. Rawlings exhibited a number of photographs on wood, which were highly admired. They were made by preparing the surface of the wood with a mixture of albumen and zinc white, rubbed in with the palm of the hand, and then coating with a film of collodion on which silver nitrate was held in suspension, the pictures being printed out under reversed negatives, and fixed, but not toned. The collodion was then dissolved off with ether and alcohol. Mr. Rawlings stated that engravers found the surface of such blocks excellent for cutting purposes. We understand that he is to read a paper on the subject at a forthcoming meeting of the Association.

Cloud Photography.—This is the title of an article in *La Nature* by M. Gaston Tissandier. It contains much instructive matter, and is illustrated by a very excellent photograph of clouds, obtained at the Pic du Midi by M. Jacques Ducorn on August 19 last. The latter, in his descriptive note, states that the only fear in exposing is that the time given may not be short enough. The ordinary method of photographing, he says, though sufficient for amateurs, leaves something to be desired for the scientific man; but, by means of isochromatic plates and a yellow colour screen (glass with parallel faces) placed within the lens, he further states that, although the screen is used, the exposure is still instantaneous, and the only fault the negatives possess is that they give the deep blue of the celestial vault as absolutely black.

Combustion of Celluloid.—The durability of celluloid and similar substances has more than once been questioned: Professor C. V. Boys has published an account of a very singular accident to a lady's dress, caused by buttons made of one of this class of compounds. She was standing in front of a fire, not blazing, but merely red; the button was entirely consumed, and others were scorched. Professor Boys has been making some "rough-and-ready tests" with one of the buttons, which, as he puts it, show that they are for all practical purposes liable to spontaneous combustion. Of course, until we knew the actual composition of these buttons, we could not justly compare them with the celluloid employed for films, but at the same time the Professor's account will cause some anxiety, and the fire insurance companies, never too eager to make things comfortable for photographers, will thus have another lever for increasing their rates, or at any rate, refusing to lower them, as it is the universal belief they ought to do.

"Truth" and the Free Portrait Swindle.—Our sixpenny contemporary, which, by the way, some years ago distinguished itself by its offensive and ignorant views on photography and photographers, has recently, *inter alia*, been having its fling at the Imperial Portrait Association, *alias* Charles Beresford, *alias* Austin & Eddy. If "Henry" had read his BRITISH JOURNAL, he would have found that his young lion had only made a second-hand discovery, that the Free Portrait trick originated in the United States, and that it was worked by one gang in this country. It seems now that "Beresford," as a new bait, professes to have bought the bankrupt stock of "Austin & Eddy," and consequently two-and-sixpenny picture-frames are now to be had at the reduced rate of—five shillings each. The other night, at the meeting of the National Association of Professional Photographers, this subject was mooted, the reply being a "non possumus." We think, however, that the Association might confer a distinct benefit on the profession and society by officially issuing a public notice warning people against Beresford, Austin & Eddy, and others of their kind.

Fading of the Latent Image.—A correspondent, in the last number of the JOURNAL, relates an experience tending to show that the undeveloped latent image, if kept for a length of time—seven years was the length in the case under notice—practically disappears, and that the paper which was exposed in the first instance may be employed a second time, and on development will exhibit little trace of the original picture. Our correspondent's experiences are very remarkable; but, as in the case we dealt with in the leader to which he refers, we are strongly inclined to refer the cause of the phenomenon to damp or gas exhalations. We do not know whether the fading might also be induced by the possible fact that the emulsion was prepared with a bromide having free bromine in it; at any rate, this, we remember, was once suggested as the cause of the fading of the latent image. *Per contra*, has it not also been contended that the latent image, instead of fading, grows by long keeping, so

that after a time properly exposed plates will exhibit the phenomena of over-exposure? Manifestly, both theories cannot be right, and, except under abnormal conditions, we fail to see how they can be otherwise than wrong.

Methylated Spirit of the Old Kind.—We append an extract from a circular that has been extensively circulated throughout the country by a firm of methylated spirit makers:—

To Photographers, Microscopists, Scientific Workers, &c.—The Excise authorities having by a recent order prohibited the sale of methylated spirit by retailers and dealers, except with the addition of a certain quantity of mineral naphtha or oil—an addition which renders it extremely unsuitable for photographic and other scientific purposes—we desire to advise you that by applying to the Board of Inland Revenue they will grant you a special authority to use the ordinary pure methylated spirit upon your satisfying them of the *bona fides* of your application and intentions. The application should be made in the first place to the officer of Inland Revenue for your district, stating the purpose for which you intend to use the spirit, and the quantity you propose to stock at one time. When this special permission is granted you, if you will forward to us an order made out on one of the official forms provided by the Excise, we will be happy to supply you with the old style of methylated spirit, free from mineral oil or mineral naphtha, at the prices as noted below.

No doubt many of our subscribers have already availed themselves of the advice. It will be interesting and useful to our readers generally if some of them will let us know of their success.

A Useful (?) Hint.—There is a photographer "out West" (it could not possibly be anywhere else) whose handsome house is said to be a monument to the prevailing vanity of women. The photographer is rich, and this is how he became so. Years ago he is said to have noticed that, when he got a lady sitter with a pair of small feet, she generally liked to place herself so that her fairy-like supports were just visible, while the lady with the large mis-shapen hoofs kept her feet out of sight. From this he inferred that the latter person would much prefer to have two small feet also, and, if she had them, she would want to display them; and then he conceived the inspiration of keeping feet on hand, and supplying them to customers who needed them. He has a dozen pairs of them—small wooden feet, with adorable boots on them—and attached to each of them is about eight inches of leg, clothed in neat stockings, and with a hook about half way up. The lady with the glorious extremities is planted in a chair, with her massive limbs and copious boots hidden as far back as they can go without dislocating her knees, and then the artificial legs are carefully hooked on to the inner hem of her dress. Consequently, she looks like a person reclining in an easy attitude, with her beautiful feet exposed by accident, and, if she can stand the strain, the resulting photograph is a beautiful thing to look at. If she can't stand the strain, her real feet come forward just in time to keep the unnatural attitude from wrenching her joints asunder, and then she appears in the negative as a quadruped. Ha! ha! "Se non è vero, è ben trovato."

Aluminium Vessels.—The use of aluminium vessels for storing, measuring, and carrying liquids, in lieu of the costly glass measures—costly through the inevitable breakages—will commend itself to the photographer if, as we may expect, they are producible at a comparatively low price. It has been asserted by two German experimenters that such vessels are unsafe to use on account of their being soluble in various menstrua. Professor G. Lange, however, contradicts the statement, and publishes in the *Engineering and Mining Journal* an account of an investigation he has made into the subject. Not to burden our readers, we may extract a portion of the conclusions that he has arrived at, as stated in his paper. He says that many portable liquids are practically inert. "Taking the worst case found, that of acetic acid, we find a maximum attack of less than 5 milligrammes per 100 square centimetres in six days." Reduced to practical results, this is equal to a litre measure (nearly a quart), losing 5 milligrammes a day, even if it were always full, or 1 gramme in 200 days; and only in 55 years would it be reduced to half its weight. Alcohol pure of fifty per cent. strength lost ·61 of a milligramme in six days per 100 square centimetres of surface; and in the same time a five per cent. solution of tartaric acid lost 1·69 milligrammes; five per cent. solution of citric acid, 2·15; one per cent., 2·15 milligrammes; but a quarter per cent. of salicylic acid, 6.35—perhaps a misprint for 0·35. It will thus be seen that, for any but the most delicate operations, such vessels would be practically untouched during the ordinary usage of the dark room.

WHY PHOTOGRAPHS FADE.

II.

Before we make an examination into the contributory causes which the various manipulatory details of photographic printing tend to produce in the fading of our prints, it would be as well to clearly understand the action of the various agencies which cause this destruction.

By far the most serious that we have to contend against is the action of the sulphuretting compounds in the atmosphere; indeed, the injury produced from any other cause may almost be put down as due to preventable causes. For instance, if we take the action of damp, where the decomposition of the size in the paper forms a destructive mouldiness which causes the fading of the picture. Here we have conditions to which I do not consider it is fair to put such a thing as a photograph, because it is due to an injury to the paper itself, and I think common care should be taken with them, as with a water-colour painting or an engraving.

Albumen prints being the greatest sufferers from damp, if a photographer knows his prints are going to be hung in a damp place, in a showcase on a platform wall at a railway station, for instance, he had better put them in nearly boiling water for a short time, to remove the size before mounting them.

The destructive action of oxidising agents is one which, in the case of gelatino-silver emulsion papers, is not receiving nearly the attention at the present time, either by the manufacturers or photographers generally, which I think it ought to. I am not referring so much to the substances used in mounting, which generate an acid by fermentation, but to the use of acids, and especially to the use of alum, whether in the emulsion or when hardening and clearing the prints.

When I say that in a series of experiments which I made some time since, to test the relative capability of various photographic prints to withstand oxidation, I found that in the case of one popular emulsion paper in the market that the images on the prints were destroyed, indeed, there was not the slightest trace left of a picture, and I think it most probable that this was due to the presence of alum in contact with the silver in the gelatine film, it having been added during the preparation of the emulsion, and I am much afraid that in the future this paper may get a bad name in consequence; and the worst of it is, emulsion papers of all kinds will suffer as well. The public will get to group them as all bad alike.

Possibly clearing the prints after development with a weak acid bath, *if they are thoroughly washed afterwards before being put in the hypo bath*, may not do much harm, but it all depends upon the thorough washing.

With albumen prints I do not think we have the same need to fear injury by oxidation as with the gelatino-chloride or bromide developed prints, as the albumen evidently acts as a preservative.

To return to the subject of the injury to the prints caused by sulphuretting compounds in the atmosphere, acting upon the paper or the substance forming the image. With regard to the paper, of course the high lights of the picture depend upon its whiteness, and, for myself, I do not consider that any photograph can be called permanent if there is any loss of the purity in the whites, due to chemical compounds left in the paper, which in time cause the latter to yellow under the action of the sulphuretted hydrogen in the atmosphere.

Indeed, in nine cases out of ten, the fading of a photograph is due to the yellowing of the whites of the picture, and not to the obliteration of the image itself, so that, practically speaking, it is of far more importance to manufacturers as well as photographers to look after the purity of the paper used, and to see that nothing is left in it which will in time cause it to yellow, than even about the stability of the image itself. Under ordinary conditions an image of silver can be made sufficiently stable, but, of course, a *printing-out* process in another metal which did not change into a yellow sulphide would be better if it could be worked with as much certainty, and with as few manipulatory drawbacks, as a silver printing-out process.

The great requirement for a sample of paper to be adapted for photographic purposes is, that it must not only be uniform in texture, but like an engraving, or for a water-colour painting, must not con-

tain in the sizing, &c., anything that will cause it to yellow in a few years.

Some experiments which I have made, by subjecting about fifty samples of papers prepared for photographic, drawing, and other purposes, to the action of sulphuretted hydrogen, showed that the photographic and the good drawing papers answered these conditions perfectly, and that they did not in themselves contain anything injurious. I wish I could say the same after these papers had been sensitised, or otherwise prepared for photographic uses. But when one sees the white paper of a so-called permanent photograph turned to something the colour of an Australian sovereign, one begins to think it is about time to inquire into the subject.

HERBERT S. STARNES.

IMPROVEMENTS IN THE TELE-PHOTOGRAPHIC LENS.

In the paper that I contributed to the Camera Club I pointed out that, in the tele-photographic lens there exhibited, I believed I had accomplished the best possible result with the least expenditure of optical means. That lens, as your readers will remember, consisted only of two cemented combinations. It is well known that any single aplanatic lens can only define properly for the axial pencil, the definition falling off very rapidly when the pencils become even slightly excentrical, for this reason: In using two combinations only, the correction for the excentrical pencils has to be accomplished by a proper form ascribed to the negative element. The main drawback to this lens is that, although it may be corrected for outstanding spherical aberration *for any particular plane*, it is not rectilinear, and, moreover, it is impossible to make it so.

At the time of reading the paper I mentioned that I was engaged upon the construction of a series of negative elements, to be employed in conjunction with rapid portrait lenses of short foci.

As your readers are well aware, the main object in photographic lens construction is to attain the best possible definition for the excentrical as well as the central pencils; and, in rapid portrait lenses, the number of elements employed enable this to be carried out to a much greater extent than is the case with a single combination lens.

The improvement that I have made consists in employing, in conjunction with a particular type of portrait lens, a compound symmetrical negative element that is practically aplanatic in itself, and is also corrected throughout its entire field, but of negative focus. This construction permits of an excellent correction for the excentrical as well as the central pencils, and reduces distortion to a minimum. Another feature in employing the particular form of portrait lens (introduced by my late father) is the possibility of correcting the complete combination (positive and negative) for outstanding spherical aberration throughout the entire field, for any chosen plane of object or screen. If a lens of this form is properly corrected for a near object, it will be found, on employing the same instrument upon a distant object, that it is no longer perfectly corrected, but outstanding aberration asserts itself. By employing the form of portrait lens illustrated in Fig. 2, a slight separation of the back lens will entirely remove this.

This matter might strike one at first sight as being of little importance; but such is not the case, in that the main feature in the utility of this type of lens for ordinary purposes consists in the employment of *as large an aperture as possible*, first on account of rapidity, and secondly on account of the fact that the larger the aperture the larger is the field that is covered or angle included. Were it not for the possible means of correction referred to by the separation of the back elements of the portrait combination, the only other method of correcting the outstanding aberration would be the employment of diaphragms, that would very materially affect both the important considerations.

I have been asked, on frequent occasions, whether still larger amplifications could not be attained with the same camera extension? This, of course, is possible by employing negative combinations of shorter foci than the particular ones which I have considered a useful mean both for the angle included and adequate intensity.

It is a very simple matter for a given extension of camera to make the amplification very much greater than that which I have adopted; but the drawback is that the angle included again becomes very small, and the loss of light considerable.

DESCRIPTION OF DRAWING.

Comparing Fig. 1 and Fig. 2, the positive element P, represented as a single lens in Fig. 1, is replaced in Fig. 2 by a portrait lens P, and the single negative element N, in Fig. 1, is similarly replaced by the double combination negative aplanatic system N in Fig. 2.

When the lens L of the portrait combination is in its primary position, the correction of the negative combination is adjusted for near objects; but, if the lens be focussed on receding planes, by the

FIG. I.

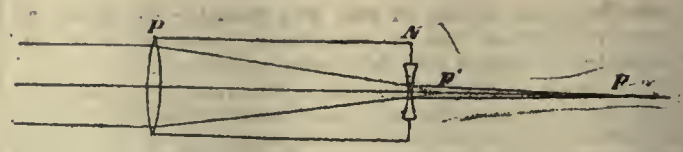

FIG. II.

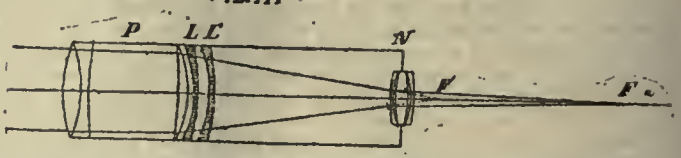

slight adjustment of unscrewing the back cell, and slightly separating the components of the posterior combination, a perfect correction for spherical aberration can be attained.

Again, if a telephoto lens of any fixed construction be focussed upon an object with a short extension of camera, it will be found that it is not perfectly corrected for a greater extension of camera. This, again, may be corrected in a similar manner by a slight adjustment of the back lens L of the portrait combination. T. R. DALLMEYER.

ELEMENTARY NOTES ON PHOTOGRAPHIC LENSES.*

STOPS.

THE *diaphragm*, or *stop*, is a metal plate having a circular aperture, which becomes the effective area of the lens by only allowing a beam of light its own diameter to be utilised in forming the image. As the rapidity of the lens depends entirely on the amount of light that it transmits to the plate, it is directly proportionate to the area of the stop. This area varies as the square of the diameter, so that, with a given lens, a stop of one inch diameter is four times as fast as one half an inch.

The rapidity does not depend on the actual measurement of the stops, but on their relation to the focus of the lens, their size being expressed in fractions of the focus, so that a stop one inch in diameter, used with an eight-inch focus lens, would be called *f*-8, generally written as a fraction, in which the letter F takes the place of the numerator, the fractional figure the denominator.

Stops are usually arranged in sets, the following fractions of the focus being the standard of the Photographic Society of Great Britain, and almost universally adopted:—Focus divided by 4, 5½, 8, 11, 16, 22, 32, 45, and 64. Each of these is twice the area of the following ones, and consequently each requires double the exposure of the preceding.

The *full aperture* or largest stop of a portrait lens is generally one-fourth of the focus, in a few special cases one-third to one-half. The euryscope *f*-5½ or *f*-6. The rapid rectilinear, one-eighth; the single landscape, one-eleventh to one-sixteenth; the wide-angle rectilinear, one-sixteenth.

All lenses are of equal speed when the aperture is the same proportion of the focus, the rapid types gaining their rapidity from their construction allowing the larger aperture to be used. A portrait lens, when stop *f*-16 is inserted, is no quicker than a wide-angle rectilinear with the same aperture.

Photographers generally use stops for one purpose far more than any other, viz., obtaining depth of focus, or the power of rendering objects at different distances reasonably sharp at the same plane. Absolute definition in the various images is impossible, but in ordinary work a slight departure from mathematical exactness in this respect is an advantage rather than otherwise. If a prominent feature in a landscape is sharply focussed with the full aperture of the lens, most other parts are fuzzy or out of focus, while by inserting a stop all may be rendered fairly sharp. No amount of reduction in the size of the stop will change the plane of greatest sharpness for any object, or alter the relative distances of correct focus; but, by reducing the diameter of the circle of light that takes the place of what should be a point, it produces apparent sharpness. When a large stop is used, if one object, whose focus is at A in diagram 9,

* Continued from page 155.

is sharply defined on the ground glass, all points in another, whose focus is at B, will be represented by circles of light, whose diameter is equal to

the heavy line in the diagram, and be simply a hazy mass. By inserting a stop the diameter of these circles is reduced in proportion to its size, as in the lower figure, and the object appears fairly well defined.

All lenses of the same focus have equal depth when used with the same stop, though many opticians will tell you in their catalogues that certain lenses that they manufacture possess "marvellous depth of focus." This is misleading; it is entirely independent of the construction or quality of the lens, as the diagram will show.

With an aperture of the same value, the depth of focus varies in inverse proportion to the focus of the lens, so that a sixteen-inch lens would possess only half the depth of an eight-inch if *f*-16 were the stop used in each.

From this it follows that the depth of focus depends on the actual size or measurement of the stop, and is not influenced by the focus of the lens; a stop, a quarter of an inch diameter, would give the same depth when used with a five-inch lens as it would with a twenty-inch. This is a somewhat startling proposition to most photographers, and it was first pointed out by our Mr. W. E. Debenham; diagram 10 will

easily prove its correctness. If points C and D, one inch apart, represent the points of sharpest focus for certain objects with a twenty-inch lens, a stop one quarter of an inch diameter, being *f*-80, would cause the diffusion from D to be $\frac{1}{20}$ inch diameter, where it met the focussing screen at C. By the substitution of a five-inch lens, the distance between the focal planes would be one quarter of an inch only, as E and F; and a quarter-inch stop being *f*-20 for this lens would make the diffusion one-twentieth of the distance E F, or $\frac{1}{20}$ inch, the same as the larger lens.

A second use of stops is to confer flatness of field. Not only is the curve of greatest sharpness flattened when the smaller stops are used, but the diffusion due to the curvature is reduced at the same time, and still greater apparent flatness is obtained.

In those lenses that give unequal illumination, the amount of light reaching the different parts of the plate is equalised by reducing the aperture. The reason for inequality of lighting was given in diagram 8; by comparing it with No. 11, it is evident that, by inserting a moderately small stop, the oblique ray is transmitted unbroken equally as the central.

In considering the subject of the diaphragm, it is best to give a little attention to its influence on the character of the image, as this is purely an optical question, although intimately connected with the artistic aspect of photography.

It is very frequently assumed that a picture taken with a large stop is

more brilliant than if a small one had been used, the principal basis for this assumption being the brilliant effect on the ground glass, with all the colours vividly portrayed in the one case, contrasted with the dull, almost uniformly dark, and lifeless scene that takes its place in the other. This is simply due to the amount of light in the latter instance being too small for the gradations to be visible to the eye; the relation between the high lights and deep shadows, and the intermediate range of tones is exactly the same in each case, and, if the exposures given with the two stops were correctly proportioned to their respective sizes, the negatives would be equally brilliant. They would not be the same, however, in other respects, the aperture influencing largely the atmospheric effect.

In a landscape negative, taken with a very small stop, the most distant portions are practically as sharp as the foreground, and the effect of distance is lost, while, if the aperture were enlarged just sufficiently to throw the distance very slightly out of focus, to the extent of slightly diffusing or softening the outline, the effect of atmosphere intervening between the observer and those planes of the picture is secured, and gives "distance" independently of the linear perspective rendering. Care must be exercised to avoid exaggerating this diffusion or softening of outline, and so destroying the effect that it is intended to produce. In many photographs sent to our leading exhibitions the advocates of the "Naturalistic" or "Impressionist" school have carried this diffusion to such an absurd degree that the distance simply becomes a meaningless mass devoid of all form and character, and, instead of suggesting soft, hazy distance, its only effect is to irritate the eye—the extreme opposite from that which would be produced by Nature herself.

It may be considered a correct principle, that softening of outline should never be sufficient to destroy the texture, form, or character of the object photographed.

The general principles governing the use of stops may be briefly expressed: the depth of focus and atmospheric effect depend on the actual size of the stop, the exposure on its relation to the focus of the lens.

HENRY W. BENNETT.

(*To be continued.*)

NOTES ON SOME NEW RAPID ORTHOCHROMATIC COLLODIO-BROMIDE EMULSION PROCESSES.

GELATINE dry plates have now taken such a hold on the photographic world that it would be almost useless to expect any general return to collodion, whatever its advantages might be. For all ordinary purposes ready-made gelatine plates must remain the most convenient medium for the sensitive film. There are, however, many photographic operations in which certain qualities are required in the negative or transparency which are far better obtainable with collodion than with gelatine, and this is the case with most of the copying processes used for the reproduction of drawings and works of art in line or half-tone. Here, in Calcutta, we are obliged to use the old wet collodion process for all our copying work in the Survey of India Office, and the same is the case in most of the establishments in other parts of the world working process blocks and other photo-mechanical processes for reproduction of line-work. Now, as some of you may know, the practice of the wet collodion process is attended with many inconveniences in the way of nitrate of silver baths, which are difficult to preserve in good order, and keep one's fingers in a state of perpetual blackness, the drying of the films, and other troubles, which may be all avoided in working an emulsion process. As collodion processes go, the wet process is fairly sensitive, and though far below gelatine in sensitiveness, it is, as a rule, much quicker than the ordinary dry collodion processes, and for this reason the latter have, so far as I know, not generally come into use in establishments like ours, where a large amount of copying work is done, and wet collodion has so far held its own.

I have often thought that the experience gained in making the highly sensitive gelatine emulsions might possibly be applied to the preparation of very sensitive collodio-bromide emulsions, and it has, in fact, already been done by Captain Abney and others, but with very little practical experience in emulsion-making with collodion, one did not quite know what process would be likely to best answer for ordinary work.

When I was in Europe last year, I was told in Berlin of an orthochromatic collodion emulsion, prepared by Dr. E. Albert, of Munich, which was said to give very good results, and to be very sensitive. So, being afterwards in Munich, I paid a visit to Dr. Albert, who very courteously showed me a good deal that was interesting, and I was specially impressed by the sight of his negatives of copies of paintings taken with his orthochromatic collodion emulsion. I have never before seen such fine negatives, full of the most brilliant soft gradation and detail, and of the beautiful violet-purple colour of the best wet collodion negatives which one misses so much in gelatine, and which indicates, moreover, an exceeding fineness of deposit. The process seemed a most valuable one, and I should have got some of the emulsion for trial, but was told that it would not keep in a hot climate. Dr. Albert's emulsion has been on sale in Europe for the last year or two, but little was known of the process of preparing it, except that the coloured solution contained one of the eosine dyes and some picrate of ammonia, the latter serving in place of a yellow screen.

Shortly after my return to Calcutta last November, I read in *Paris Photographe*, M. Nadar's excellent monthly, an extract from the *Correspondenz*, of a paper by Dr. A. Jonas, of Vienna, describing some experiments he had made, at Dr. Eder's suggestion, in preparing an emulsion similar to Dr. Albert's. It seemed to me worth trying these formulæ, and when I did so, I was quite surprised at the results obtained, and especially by the wonderful sensitiveness conferred on the emulsion by the addition of the strong picrated erythrosine-silver solution, so that the coloured collodion emulsion was about as sensitive as ordinary gelatine dry plates. No such enormous rise in sensitiveness is noticeable in orthochromatising gelatine dry plates with weaker erythrosine-silver solutions.

Dr. Jonas's method of working, as given at length in the *Photographisches Correspondenz* for July, 1891, is briefly as follows:—

The employment of the silver and ammonia method of preparing the silver-bromide emulsion, which is so successful with gelatine, does not answer so well with collodion, because the free ammonia acts injuriously on the collodion. This difficulty is overcome in the following process by neutralising the free ammonia with acetic acid; and, moreover, the emulsion so obtained is exceedingly fine in the grain and creamy.

SOLUTION I.

Ammonium bromide	64 grammes.
Distilled water	80 c.c.
Absolute alcohol	800 ,,
Thick collodion (four per cent.)	1500 ,,
Glacial acetic acid	65 ,,

The ammonium bromide is first dissolved in the water with heat, then the alcohol, collodion, and acetic acid are added in order.

For the collodion I have used a mixture of equal parts of four per cent. solutions of Schering's celloidin, and of a collodion made with Morson's pyroxyline, both in equal parts of ether and alcohol, the same as ordinarily made up in the office for copying maps, but thicker.

SOLUTION II.

Crystallised nitrate of silver	80 grammes.
Distilled water	50 c.c.

The silver salt is dissolved in the water with heat, and then strong solution of ammonia is added in small proportions till the precipitate is redissolved (this takes about 72 to 75 c.c.); 800 c.c. of alcohol, warmed to about 45° C. (113° Fahr.), are then added. This solution should remain clear and colourless. If it turns brown, the alcohol is impure. Both solutions can be prepared in daylight.

When solution II. is ready, it is poured in a thin stream into No. I., the latter being well shaken meanwhile. This operation must be performed in a dark room, with orange light. Solution II. must be kept heated from 40° to 50° C. (103·5° to 122° Fahr.), otherwise the silver-ammonia salt will crystallise out; it is desirable, therefore, to stand the solution from time to time in a water-bath heated to the above temperature. The mixing of the above quantity of emulsion should take about ten minutes. The emulsion is well shaken up and tested for acidity. A little of it being poured on glass, and wetted with water, should show a slightly acid reaction. If alkaline, it is acidified by adding acetic acid drop by drop. It is then well shaken for about a quarter of an hour, and, after standing for an hour, is poured into five or six times its volume of water. The silver bromide collodion separated out is collected in a clean linen cloth, and the ends of the latter being tied so as to form a bag, is washed in running water for about a couple of hours. It is then finally washed with distilled water, and spread out upon a thick layer of blotting-paper to dry, which takes one or two days. The dry silver bromide collodion can then be kept in black bottles in a dark place for use as required.

I found no difficulty in following Dr. Jonas's instructions, but the mixed emulsion was kept for a day before being washed, with the object of getting greater sensitiveness, and it might possibly be kept even longer with advantage, because I noticed that the unwashed emulsion gained sensitiveness by keeping, and also became much more uniform in texture, though thinner. After a week it became very thin.

To make the final emulsion, dissolve—

Silver-bromide collodion	6 grammes.
Alcohol	40 c.c.
Ether	60 ,,

The sensitiveness of the emulsion is, after an hour, about ½° Warnerke. After twenty-four hours' ripening at 60° to 70° Fahr., it increases about two or three times, and the colour of the silver bromide changes from red violet to blue violet.

All chemicals must be perfectly pure, and the greatest cleanliness must be observed in all the vessels employed.

The mixed washed emulsion can be kept ready for use; some I prepared about a month ago is now in very good order.

I have found that the emulsion can also be used unwashed with good results. At first it gives rather dense pictures, with very clear shadows; but, after a few days, it is more sensitive, and the image not quite so dense and hard; the film also becomes more uniform in texture. After a week, though more sensitive, it gives thin images slightly inclined to fog with the para-amidophenol developer, and the results obtained with the washed emulsion are certainly better. The unwashed emulsion would probably work well if used within three or four days of being made up, and would, of course, be more economical for the work on the large scale.

COL. J. WATERHOUSE, S.C.,
Assistant Surveyor-General of India.

(To be continued.)

ELECTRIC LIGHTING FOR PHOTOGRAPHERS.

IN our last issue we mentioned having inspected an electric lamp for studio purposes made by the Pilsen Electric Company. Since then we have received several requests for a fuller description of the apparatus employed, with which we now take the opportunity of complying.

The apparatus consists primarily of a suspension arrangement, a reflector, and a large current arc lamp. The suspension arrangement consists of a bar held at its centre, with the lamp and reflector hung at one end, and a

counterweight at the other. This arrangement allows the lamp and reflector to be swung in any direction without effort, so that the light can be directed on to a sitter in whatever way suits the idea of the operator. The reflector, which is made of metal and is suspended by trunnions from the end of the suspension bar, is either papered or painted a dull white on the inside, and takes the direct light from the arc, which it diffuses perfectly.

The arc lamp itself takes a current of 50 ampères, with a pressure of 50 volts across the terminals of the lamp. Its carbons are in line with the axis of the reflector, which generally is at 45 degrees to the vertical, and the most intense light from the arc is thrown into the back of the reflector and sent out direct, so that, by hanging the lamp at an angle, the only light that is lost is that which is absorbed by the white background.

Mr. Liebert, the Company's manager, after many experimental trials, has got this large current lamp to burn noiselessly for hours together. Such a result is difficult to attain, as most photographers know, because, when the carbons are not in a vertical line, the arc has much more tendency to wander about the points of the carbons, producing a roaring and spluttering that unsteadies the light as well as the nerves of the sitter, and also because large-current arc lamps are more difficult to regulate than small-current ones. To explain why this is the case, it is only necessary to point out that an eighth of an inch movement in the carbons may alter the energy consumed by the arc by two or three horse-power.

These difficulties have been got over in the arc lamp under notice, by using specially prepared carbons, which, when properly centered, keep the arc central, provided the carbons feed together without allowing the arc to get too long.

The lamp is a direct current lamp, and when it is burnt off a supply company's mains (which are generally at a difference of pressure of 100 volts) a resistance frame to put in series with the lamp can be supplied. When a power plant for the lamp is put up by the Company, a four horse-power (nominal) gas engine, a shunt wound dynamo, and a smaller resistance frame to put in series with the lamps are supplied.

We can testify to the steadiness and noiselessness of the lamp, which is already being worked most successfully by several portrait photographers. We gather that the shape of the "reflector," as shown in the cut, will be modified so as to narrow the angle over which the large mass of light emitted is diffused. Altogether, we are persuaded the system is a thoroughly good and practicable one, and well qualified to meet the requirements of the great number of photographers who are anxious to adopt electric lighting at comparatively little outlay.

THE MADDOX FUND.

We append a letter from Mr. Andrew Pringle, indicating that this fund closes, for the United Kingdom, on the 31st of the present month, and also giving a list of the contributions received or promised up till the end of February. We are aware that there are many additions to be made to the list, which, before it closes, will doubtless be greatly enlarged. It should be borne in mind that the American and Continental funds are separate in administration from the English fund.

It is only just to ourselves and our readers to here point out that the final appeal and list of subscriptions already published by our contemporaries were both unauthorised and incorrect, the editors of those journals treating communications sent to them in their capacities of members of the committee as matter for publication, although the suggested circulars were plainly marked "Draft."

In recommending the fund to the favourable notice of those of our friends who have not yet contributed to it, we deem it necessary, especially for the information of our younger readers, to lay stress on the fact that the claims of Dr. Maddox to the credit of his gelatine emulsion experiments were admitted, practically without dissent, for a great many years, and that it was only when the question of giving him some pecuniary recognition of those experiments was mooted that opposition to his claims broke out among a small number of persons, whose fertility of imagination and command of invective are apparently as great as their wilful distortion of photographic history and their envy of the substantial recognition of the value of Dr. Maddox's experiments, which is so freely forthcoming in various parts of the world.

"MADDOX TESTIMONIAL FUND.—FINAL APPEAL.

"*Cromwell House, Bexley Heath, Kent,*
"*February 29, 1892.*

"Since its start, this fund has been progressing satisfactorily, but the Committee feel that some period must be fixed for the closing of the Subscription List, and the *31st of March* has been chosen as the date for closing the list and making up accounts. It is proposed that the testimonial, when presented to Dr. Maddox, shall be in some such terms as follows:—'This Testimonial is presented to Dr. Richard Leach Maddox, in recognition of his services to photography, and especially of his investigations in connexion with gelatine emulsion.' Appended is a list of subscriptions paid or promised in the United Kingdom, and it is hoped that those who sympathise with the object will give notice of their intention to subscribe, stating the amount as soon as possible to the Hon. Treasurer.

"COMMITTEE:—James Glaisher, F.R.S., *Chairman*, Captain W. de W. Abney, R.E., C.B., F.R.S., W. S. Bird, George Davison, A. Haddon, A. H. Harman, Charles W. Hastings, T. C. Hepworth, Dr. A. C. Mercer (New York), Henry Sturmey, J. Traill Taylor, W. H. Walker, Sir H. Trueman Wood, F. York. *Treasurer*, Francis Cobb, Riverdale, Twickenham."

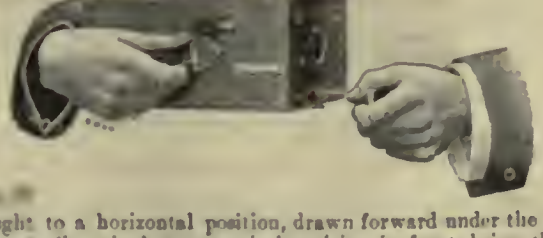
Our Editorial Table.

THE SHUTTLE HAND CAMERA.

GEORGE HOUGHTON & SONS.

THE Shuttle hand camera has the advantage that it does not much exceed the size of the plate for which it is intended, and the arrangement for changing plates is simple and novel. The plates previously placed in sheaths are stacked in the back of the camera, and after the first exposure, by ingenious mechanism (the act of changing being shown in the cut), the last or back one of the series



is brought to a horizontal position, drawn forward under the others, and eventually raised to a vertical position in front, being then on the focussing plane. The operation of changing the plates also sets the shutter, the movement being the simple drawing out of a rod and pushing it home.

THE Leeds Photographic Society's syllabus, rules, list of members and list of books in the library, is comprised within the dimensions of a neat little book, whose natural resting-place would be the waistcoat pocket. It also contains spaces for memoranda.

WE have received the results of meteorological and magnetical observations at Stonyhurst College Observatory for 1891. The

compilation, which is by the Rev. W. Sidgreaves, S.J., is of interest to astronomers, meteorologists, and others, to whom, no doubt, the observations recorded will be of abiding value.

Photographic Mosaics, 1892.

Edward L. Wilson, New York.

Following a *resumé* of the progress of photography during 1891, drawn by the editor from the writings of the principal photographic authors, *Mosaics* presents its readers with a large number of specially written articles, having familiar names appended to them, and all eminently readable. The book is illustrated to a more liberal extent than in former years, the frontispiece being a portrait of Mrs. Potter Palmer, President of the Board of Lady Managers of the World's Columbian Exposition, evidently "a fine figure of" a lady.

The Art of Retouching Negatives.

London: Marion & Co.

A new edition of Mr. Robert Johnson's work under the above title indicates that it has been favourably received by the public. Mr. Johnson treats on the texture and modelling of the eye, the mouth, the hair, and the other portions of the figure which require the aid of the retoucher. Accessories, backgrounds, the finishing of photographs in oils and water colours and composition, all fall under the author's treatment. We are rather unable to understand his meaning in saying (in a chapter devoted to "The Eye Compared with the Lens and Camera") that a single lens is unsuitable for groups because of its making the near figures on a larger scale than those farther away. This is not a special property of any lens, single or compound, but one in strict accordance with the laws of perspective.

Bromide Paper: Instructions in Contact Printing and Enlarging.

By Dr. E. A. Just. Bradford: Percy Lund & Co.

This is a condensed translation by Messrs. W. E. Woodbury and H. Snowden Ward of a work by Dr. Just, published in Vienna during the year 1889. It is perhaps the most exhaustive monograph on the subject yet issued, no detail connected with bromide printing and enlarging being, so far as we can see, omitted. Especially valuable are the sections treating of the various systems of lighting which may be employed in printing, while that which deals with enlargement by projection is equally clear and full. A great deal of the matter is, however, written from a purely scientific standpoint, which, if it does not appeal to the ordinary level of photographic intellect, will not perhaps lack appreciation at the hands of the more advanced practitioners. The work has a capital frontispiece in bromide from a negative by Mr. Wellington, and there are over thirty well-drawn illustrations in the text.

PATENTS COMPLETED.

Improvements in, and in connexion with, Photographic Printing Apparatus, an Improved Method of Preserving Sensitised Paper, and a Protective and Adhesive Solution therefor.

No. 1953. Richard John Wynkoop and John Morris Kemp, both of Paterson, County of Passaic, and State of New Jersey, U.S.A.—*February* 3, 1892.

This invention relates to an improved machine or apparatus for rapidly printing and trimming or cutting photographs.

The object is to provide means for contact printing, and the invention consists in apparatus for holding films or sensitised paper in close contact with a photographic negative during exposure, and in certain other novel features of construction and combination of parts, as will be hereinafter described and pointed out in the claims.

[Here follows a detailed description of several drawings illustrative of the invention, after which the patentees proceed]:—

For protecting the sensitised surface of the photographic paper, and for preventing chemicals or impurities in the back of the paper from contact with the sensitised surface and destroying it as a whole or in spots, we provide a preservative solution for application to the back of the sensitised paper, which will hold back the chemicals or impurities therein from contact with the sensitised surface, thus enabling the paper to be kept for any length of time without injury to the sensitised surface.

In addition to the preservative quality of our solution, it is also adhesive, so that the ordinary paste for mounting prints on cardboard is dispensed with.

The ingredients generally employed are as follows, and in about the proportions named, to wit:—

Gelatine or glue	2 ounces.
Water	40 ,,
Alcohol	10 ,,
Sugar	1 ounce.
Chrome alum or alum	5 grains.
Glycerine	2 drachms.

These may be combined in any approved manner, but we prefer to dissolve the gelatine or glue and sugar in the water, and mix therewith the alum and glycerine, after which the alcohol is added. When applied to the back of the sensitised paper it produces a thin pliable coating or skin, which, as previously stated, prevents impurities on the back of the paper from contact with the adjacent sensitised surface, and also, when moistened, forms an excellent adhesive for the cardboard or other back.

New or Improved Figures or "Puppets" for Magic-Lantern Displays, and Apparatus or Mechanism for actuating same or the like and in connexion therewith.

No. 3727. William Cheffins, Holbeach, Lincolnshire.—*February* 6, 1892.

This invention consists of (firstly) transparent automaton figures, representations, or puppets for magic-lantern displays—that is, figures, &c., which are transparent, so that the colouring, shading, &c., of such figures, &c., is, when shown in the magic lantern, reproduced; and (secondly) this invention consists of apparatus or mechanism for actuating such figures or the like, or in connexion therewith, so that such figures or puppets, being arranged, constructed, and mounted in conjunction with the "slide" or framework in which they are held while being displayed in the lantern, that such figures or puppets can be caused to move as in the action of walking, running, boxing, fencing, or gesticulating, or other movements, grotesque or otherwise.

Or these transparent automaton figures or representations may be mounted in any other suitable or convenient manner (as on a trapeze), and actuated in any well-known or suitable manner independently of my improved actuating mechanism, &c., which latter again may be used independently of my new or improved transparent automaton figures.

Heretofore, slides having moving figures or representations have been used in magic lanterns, as I am well aware, but such moving figures or reflections have been produced by painting, or otherwise producing pictures or figures on the glass or transparent part of the slide itself, and then moving such glass about—this has shown a reflection of a moving figure, &c., but the effect has been rather of a "fixed" nature and the success doubtful—as the fixed figure could only be made to move, and not the separate parts thereof, as with my automaton transparent figures.

My invention is as follows:—

First: The automaton figures, representations, or "puppets" (as I call them) are made of talc or any like equivalent transparent substances. For the sake of example, I will describe one figure only, and that the figure of a man.

The legs are jointed to the hip, and the knees also jointed if desired, and the arms jointed to the shoulders, as also the head and neck if desired.

The face, hands, clothes, &c., may be suitably coloured as desired, care being taken to leave the parts transparent where required, whilst those parts where the joints occur, or mechanism connected, or other parts also, may be rendered opaque so as to hide same.

Such "puppets" may then be arranged and mounted, and actuated or not as desired in any well-known or suitable manner, and one or more of these "puppets" may be arranged to perform and be shown at one and the same time.

These puppets are particularly adapted to be displayed and actuated by the following means, which constitute the second part of my invention, viz.:—

Second: Continuing the example of a figure of a man, one foot of the figure is attached to a projection or part of a peculiarly shaped support, the other foot being similarly attached to a second corresponding support.

Each such support may be advantageously formed of tin plate or other thin sheet metal, and has a wide turned-up edge or flange formed at right angles to the plane of the figure, &c. This flange is to form a bearing surface upon one edge of a kind of trough slide or magic-lantern slide, having a space between two transparent glasses, in which space these figures can be displayed.

These two supports (to which respectively the two feet of the figure are attached) are combined, and retained together either by the one having a bolt head thereon, working in a longitudinal or other slot in the other, or by the one having a lug thereon carrying a headed pin, which works in a slotted link pivoted to a similar lug on the other, or equivalent mechanical arrangement, so that these two supports can freely move in the direction of the planes thereof, but not away from or apart from one another.

Any suitable lever, cranks, pulleys, belts, bands, or connexions may be used in addition to the above-described invention, if required or desired.

Improvements in the Method of and Means for Modelling by the Aid of Photography.

No. 22,825. Hermann Pötschke, 4, Bergmannstrasse, Berlin. —*February* 6, 1892.

This invention relates to a method of and means for modelling by the aid of photography either on a reduced or enlarged scale, or to the natural size, and which is generally applicable to all objects which may be conveniently photographed, as hereinafter described, but is more particularly intended for the modelling or production of portrait busts.

In proceeding according to these improvements there are four principal operations, which consist in: (1) Taking photographic negatives; (2) producing silhouettes; (3) composing or joining together the silhouettes; and (4) filling in the intermediate spaces left between the silhouettes.

It will be assumed that it is desired to model the portrait bust of an individual. If we imagine a series of vertical planes, each passing through the vertical axis of the head of this individual, each of the planes will divide the surface of the head and bust of the person into two equal parts. If, again, we assume each of the planes to be non-reflecting and opaque, and a strong light to be exhibited on one side, it will be evident that only the lighted part can be photographed. If, then, successive planes be employed in successive longitudes, or if the sitter be rotated through successive angles in the same plane, a series of photographic silhouettes may be obtained covering the whole surface of the head and bust of the sitter.

The negatives must be taken in a chamber, the floors, walls, and roof of which are non-reflecting.

In order to secure the axis of the head of the sitter in a vertical line, a flat horizontal ring or head-rest is employed. By means of radial studs or adjusting screws in the ring, the head may be brought into the exact desired position and fixed there. It is preferred to employ a rotating chair, and it is more convenient to rotate the sitter than the source of light, screen, and photographic apparatus.

During the intervals which separate the taking of the negatives, the chair and sitter are turned through a certain number of degrees each time, until the number of exposures required for the whole circumference have been made. The number of degrees or the angles through which the sitter has been successively turned must be carefully noted, as this information is subsequently necessary in arranging the silhouettes together. A similar result is obviously obtainable by keeping the sitter stationary, and successively moving the whole of the apparatus around him through the whole circumference; or separate sources of light, separate screens, and separate cameras may be employed for each exposure; but, in all cases, each exposure should be numbered, and the angle between it and the previous exposure noted.

The hair, eyebrows, beard, and moustache should be powdered with flour or white powder before the exposures are made, particularly in the case of persons with dark hair.

Photographic copies or positives are taken from the negatives on thin sensitised sheets of metal, such as copper, the sensitised surface being formed upon an etching ground or varnish. The outlines of the silhouettes are traced through the etching ground with a needle or graving point, and are then etched through, thus separating the silhouette from the rest of the plate. The head-rest or ring which is photographed in each negative must be left upon each silhouette as a horizontal strip which becomes of service when the silhouettes are arranged together in the following operation.

This operation requires a suitable frame, which consists of a vertical cylindrical core and an upper and a lower horizontal ring. The core and rings have formed in them vertical radial slits at exactly the same angles as those at which the various negatives were originated in the photographic process. The silhouettes are arranged in this frame in their proper order, with the horizontal strips (*i.e.*, the photographs of the head-rest) which have been left on them fixed to the upper ring. The back edges of the silhouettes, which represent the vertical axis, are brought together at the axis of the core of the frame. Thus a radial skeleton outline is obtained, which represents the outline of the head and bust by means of a number of meridian-like lines formed by the front edges of the silhouettes, and this outline is in exact accordance with the reality. Between the silhouettes angular spaces are left which have now to be filled up.

The angular spaces which are left between the silhouettes are now filled in with modeller's clay, wax, or other plastic material, starting from the core or centre. By gradually filling it from the centre all round, the silhouettes become gradually fixed, so that the supporting rings may soon be cut away, leaving the modeller unhampered in his work.

For the face, which requires much greater care to secure the proper expression, the angles at which the successive negatives are taken should be much smaller than for the remainder of the work. The larger the number of silhouettes taken, the more easy will be the subsequent modelling and the more accurate the final result. An expert modeller will be required for the finishing touches.

The portrait bust thus modelled may be reproduced in the usual manner.

In the foregoing description reference has been made only to the production of portrait busts, but other objects may be similarly reproduced by the same means and in the same manner, and more particularly sculpture and similar works. The process is especially adapted for reproducing suitable works of art on a reduced or enlarged scale.

Claims: 1. The hereinbefore-described method of modelling by the aid of photography, substantially as and by the means set forth. 2. In the process of modelling by the aid of photography, taking a series of negatives from different points of the person or object to be modelled, the person or object being partly lighted and partly in deep shadow, and the camera being arranged in such case to take a sharp photograph of the line dividing the light from the shadow without foreshortening, substantially as hereinbefore described. 3. In the process of modelling by the aid of photography, producing silhouettes in sheet metal, or similar material, by photographic printing and etching from the negatives produced as described in the preceding clause, substantially as hereinbefore described. 4. In the process of modelling by the aid of photography, arranging the silhouettes produced as set forth in the preceding clauses radially around a central core, and filling up the space between them with suitable plastic material, substantially as hereinbefore described. 5. Silhouettes for modelling by the aid of photography, produced as hereinbefore described, and having a projection corresponding with the head-rest or ring, for the purpose of serving as an index or datum in arranging the silhouettes, substantially as hereinbefore described.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

March 8.—Ordinary Meeting, the President, Captain W. de W. Abney, F.R.S., in the chair.

The President announced that the Devon and Cornwall Camera Club, the Ealing Photographic Society, the Glasgow and West of Scotland Photographic Association, the Glasgow Photographic Society, and the Southsea Photographic Society had been admitted to affiliation of the Society.

The President also stated that Mr. F. P. Cembrano, jun., had been elected to fill the vacancy on the Council caused by the recent changes.

A paper on *Photography as Applied to the Detection of Crime* by Dr. Jaffarent, of Berlin, illustrated by a number of lantern photo-micrographs and other slides, was read by the Honorary Secretary. The author remarked that recent laboratory discoveries had developed corresponding evils, as the criminal had adapted them to his own ends, and thus certain kinds of crime had made considerable progress of late years. But, in the means for defeating those ends, photography by no means took the least place. The absolute accuracy with which scenes of crimes could be instantaneously photographed, as he had suggested, was a great assistance to the law. In one case, where there was a fight between a murderer and his victim, a clock had been displaced, and had stopped. In an examination of the scene, the officer did not notice the clock or the hour at which it had stopped. Had a photograph of it been taken it might have settled this and other matters. Cases occurred where the results of microscopical examinations had been doubted by the other side, but with decomposed blood, photo-micrographs could be used as positive evidence, and could be secured in an absolutely truthful manner. In detecting poison in the blood by such means, he had worked for many years. In the case of a murder he narrated how a photo-micrograph of a dog's hair, found on the body of the victim, had led to the conviction of the accused; for, from the appearance of the hair, it was judged to come from a yellow dog, which was a smooth-haired animal that had never had its hair clipped. A description of the dog was published, and suspicion fell upon an individual who possessed such a dog, hairs from which were proved to be identical with the dog's hair found on the body of the victim. The man was arrested, confessed the crime, and was executed. Another case was prepared from the hairs of the victim, a woman. On the clothes of two men suspected of the murder, a woman's hairs were found which coincided with those of the victim. The case was further strengthened by a trace of human blood on the clothes of one of the accused, who ultimately confessed to having done the deed alone. Human blood could be distinguished from animal blood by the difference in the sizes and shapes of the corpuscules by certain physical reactions, and its behaviour in polarised light. The corpuscules were disc-shaped, and could be accurately measured. A murderer had been convicted by photo-micrographs taken of a trace of blood left on an axe after it had been cleaned, having, the criminal said, been used to kill a goat. Photography, applied to the detection of the falsification of handwriting, showed that alterations and erasures could be clearly distinguished, and demonstrated the difference in the inks employed, which could not be perceived by the eye. Differently tinted inks had little effect on the eye, but, when photographed in a suitable light and on colour-sensitive plates, the difference became apparent. A number of slides were shown illustrating the inability of ordinary plates to penetrate alterations and erasures, which, with colour-sensitive plates, became plainly visible, altered figures and words being shown on various documents, the difference in the colour of the ink being readily detected by the colour-sensitive plates. In a court of law he superposed gelatine positives of an individual's characteristic writing upon the

forgery, thus proving to the judge the absolute truth of his method, which he claimed to be superior to other methods of identifying writing. Forged bills of exchange, postal orders, and legal documents, exposed in this way, were illustrated by several lantern slides. Blood taken from the body of a man who had met his death in a fire, when reproduced by photo-micrography, proved that the man was dead before the fire occurred.

Mr. ANDREW PRINOLE thought the author of the paper was, perhaps, a little too sure with regard to the possibility of differentiating the blood of mammalia from human blood. He considered it very difficult to make certain as to the difference between the various corpuscules. Of course, in the determination of a hair with the blood, the double evidence was much better.

The PRESIDENT said he once discovered a forgery by photography of the signature on an old engraving, as he was able to bring out the original signature. The engraving was supposed to be valuable, but turned out to be worthless with the new signature. He had done this in the same way as Dr. Jeserich.

A vote of thanks to Dr. Jeserich, and to Mr. Carl Gregor for having translated the paper, concluded the proceedings.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 3,—Mr. T. E. Freshwater, F.R.M.S., in the chair.

Mr. E. J. Wall was elected a member of the Association.

Mr. A. L. Henderson passed round a number of Dunmore's cloud negatives on ground glass.

Mr. J. Hay Taylor exhibited a binocular lanternescope of his own construction. It was stated that Messrs. G. Mason & Co., of Glasgow, were making such instruments.

Mr. Rawlings showed several photographs on wood. The wood was first coated with zinc white and albumen, and a film of plain collodion in which silver nitrate was suspended next applied to it. The picture was printed under a reversed negative in the usual way, the film being dissolved off with ether and alcohol. In answer to questions, Mr. RAWLINGS said the pictures were fixed in the ordinary way but not toned. Engravers found the surface excellent for cutting purposes.

A question, what functions do hydrochloric acid and nitric acid perform in emulsions, gelatine and collodion, was, after a lengthy discussion on gelatine emulsions, answered by reference to Abney's *Treatise on Photography*, in which it was stated that, if an emulsion is prepared with an excess of silver nitrate, it must be acid.

In the absence of Mr. S. Herbert Fry, who was to have demonstrated his new enlarging lantern, Mr. J. TRAILL TAYLOR, at extremely short notice, gave a discourse on *Enlarging Methods*. He said he knew nothing of the process or method of enlarging that was to have been brought before them that night, and he thought that a talk on enlarging generally and the means hitherto adopted might form a fitting introduction to a discussion on the subject. He would not however touch upon the surfaces to be enlarged upon, which might be collodion, wet or dry, gelatino-bromide, or other sensitive surfaces. Solar camera enlarging was little practised at present, thanks to the superior sensitiveness of printing surfaces, the only processes to which it was now applicable being carbon and platinum, no one thinking of printing enlargements on albumen paper. Rapidity depended upon the size of the condenser used, and sharpness was secured by an equatorial motion. Having described and figured the double condenser, by which the solar camera could be used with the electric or limelight, he said that a large volume of light could be obtained in that way, and, if the condensers were not very perfect, it was necessary to use a piece of ground glass to diffuse the light. He incidentally remarked that the limelight would probably be used more in future for enlarging purposes on account of the anticipated intense cheapening of oxygen, which, he believed, could now be made at a cost of 1*s.* 6*d.* per thousand feet, the process being the extraction of oxygen from air by permanganate of potash. He next referred to enlarging by means of radiated light from white surfaces by sun or artificial light, a piece of cardboard or the sky forming the white backing to a negative. By this arrangement no condenser was necessary, and it formed a very excellent method of producing enlargements. A modification of the lantern was made in New York, and sold under the name of the Wonder camera, and by Dancer in this country, as the Opaque Lantern many years ago. The late J. Solomon also made it, and he (Mr. Taylor) had one in his possession, which he described. It formed a pleasing way of projecting pictures or transparencies. He next described Mr. T. N. Armstrong's system, in which the negative intercepts the radiant, gas being used, as it gave greater facility than the electric or limelight or magnesium, and was cheaper. It was desirable to have two lamps instead of one, these being so placed and protected that no light fell on the surface of the negative.

Mr. A. CLARKE said this was exactly Mr. Herbert Fry's system.

Mr. TAYLOR said there was still another method which had been used and patented, consisting of illuminating the negative through ground glass, but by such a method only the centre of the negative was illuminated. It was said that equality of illumination could be obtained by increasing the number of surfaces of glass, but this was insufficient for equality. The system was bad if only one light be employed. The only way by which success could be had was by placing two other lights at the sides. A patent had been obtained for the substitution of opal for ground glass. This necessitated a fearful and wonderful exposure. Having contrasted glass coated with kaolin or baryta sulphate in gelatine with ground glass for placing between the radiant and the negative, Mr. Taylor concluded by describing the methods of daylight enlargement employed by some commercial houses, and said for the object glass there was nothing to excel the ordinary Petzval lens. Finally, he said that, in illuminating the negative through ground glass, equality might be obtained by igniting a strip of magnesium and waving it slightly to and fro.

Mr. E. MILNER described a rough-and-ready method of enlarging by means of a small and a large camera, the negative being placed at the screen of the small one, and illuminated by means of the light of magnesium reflected from a sheet of white cardboard.

Mr. W. E. DEBENHAM recommended the new Zeiss-Suter anastigmatic in preference to a portrait lens as the object glass for enlarging, the field of the former being so exceedingly flat.

The CHAIRMAN said two lights for illuminating opaque surfaces had been used considerably for lantern work, the lights being projected on an opaque object and thrown on the screen. Mr. S. Highley used to sell such a lantern. There was nothing novel in the idea.

Mr. A. HADDON suggested glass coated with plaster of Paris as a substitute for opal.

After considerable further discussion the meeting closed.

Camera Club.—March 3, Captain Abney in the chair.—A demonstration of *The Treatment of Prints by the Carbon Process* was given by the Autotype Company. Mr. SAWYER, in an address, gave a description of the process, and Messrs. Burton and Braham went through the necessary manipulations with a number of prints which had been prepared for the demonstration. A large number of fine illustrations was on exhibition in the room. On March 17, a lecture entitled, *Modern Masterpieces* (pictures and drawings shown in the lantern), will be delivered by Mr. Henry Blackburn, Editor of *Academy Notes*.

North London Photographic Society.—March 1, Mr. J. Traill Taylor in the chair.—A circular was laid before the Society from the Royal Commission for the Chicago Exhibition, and one from the Photographic Society of Great Britain inclosing the affiliation rules. Mr. JAMES MARTIN then read a paper on *Platinotype Printing*. This will appear in a future number. At the close a specimen print of some very beautiful ice crystals, presented by the lecturer to the Society, was passed round for examination. Next meeting March 16, lantern slide competition at 8.15 p.m.

Holborn Camera Club.—March 4, Mr. Binns in the chair.—A discussion on *Exposure* took place, and was eventually adjourned for further discussion until another evening. The third annual exhibition of the above Club will be held at Anderton's Hotel, Fleet-street, next Saturday (March 12).

People's Palace Photographic Club.—March 4, Mr. Thomas Lawday in the chair.—Mr. G. Kendall brought some stereographic negatives showing great flatness and want of vigour. Mr. Robert Beckett attributed this to poor light and unsuitable developer. It was stated that views in a dull or weak light should be developed with more pyro than is usual when the subject is brightly sun-lit. A 12×10 print on Fry's "Roughest" paper was exhibited by Mr. R. Edwards. This was uranium toned, and of a pleasing warm black colour. He stated that it experienced a difficulty in eliminating the yellowness left by the presence of ferricyanide in the toning solution, which clung to the rough pores of the paper.

Polytechnic Photographic Society.—March 4, Mr. J. H. Gear in the chair.—After Mr. T. Paternoster had shown and explained the various peculiarities of half a dozen patterns of flash lamps, the Chairman arranged two groups for experimental exposures. He asked the sitters to look at a bright light for some seconds so that the eyes might appear natural when the exposure was made. The lens used worked at *f*-6, and the plates being very rapid produced excellent negatives on development. March 18, *Wet Collodion*, by F. R. Tissington.

West London Photographic Society.—March 4, Technical Social Evening.—A pleasant informal gathering where various photographic matters were discussed with an absence of ceremony which was very acceptable to the majority of members present, and which enabled those gentlemen who, though talented, suffered from an excess of modesty to give the others present the benefit of their knowledge and experience, also those of the younger members who desired information on various matters, to obtain it in the course of friendly conversation. It is hoped that any gentleman who has anything the least interesting in a photographic way will bring it down to these meetings, and help to make them the success which the experience of the first evening seems to show will be achieved.

Chiswick Camera Club.—March 7.—A lecture on *The Hot Bath Platinotype Process* was given by Mr. R. W. WATSON, who said that, in his opinion, platinotype was unexcelled by any other printing process from an artistic point of view. Photographs were exhibited which showed the adaptability of platinotype to any style of photograph, interior photography being beautifully rendered by this process. The lecturer dwelt particularly upon the necessity of keeping platinum paper perfectly dry, both before and after printing.

Croydon Camera Club.—February 29, the President in the chair.—Messrs. Holland and Reeves presented the Club with framed examples of their work. Mr. Oakley showed the "Express" hand camera. Mr. CLARK read a short paper on *The Application of Air and Benzoline to the Production of an Incandescent Light suitable for the Lantern*, and by means of the aforesaid system projected a number of slides on to the screen. The illumination was by no means equal to limelight. It was decided to initiate a portfolio. Members are requested to bring over more mounted prints to the meeting on March 14, the best only to be selected for the portfolio. Extra meeting on March 11 to test Eastman's rapid bromide paper, Mr. White being the experimentalist. March 14, Mr. D. E. Goddard on *Silver Printing*. March 17, Annual Dinner at "Greyhound." March 28, Lantern Night.

Croydon Microscopical and Natural History Club (Photographic Section).—March 4, Mr. Edward Lovett (President) in the chair.—Mr. W. Low-Sarjeant exhibited an improved hand camera of his own construction. Mr. J. H. DRAGE then read a paper entitled *Pictorial Composition*. Mr. Drage hoped that, in reading this paper before the Club, the members would accept it more in the light of hints, and would give them a knowledge of the various lights, cast shadows, introduction of figures, and the general composition of pictures, balance of parts, and treatment of lines. Trimming prints was a thing photographers should be especially careful of, the horizontal lines being carefully noted, many pictures being spoilt by carelessness in this respect.

Lewes Photographic Society.—March 1, Mr. J. G. Braden in the chair.—A paper on *Kallitype Printing* was read by Mr. BEDFORD, and one of the members exhibited prints on the Eastman paper, distributed last month, which were much admired.

Midland Camera Club.—March 4, Dr. Hall Edwards in the chair.—Two new members were elected. Several members showed their prints upon the Eastman rapid bromide paper; Mrs. Welford, a negative just taken from a paper bag (when it had been two years), utterly spoiled by the paper; also a very neat leather camera case by Levy; Dr. Nichol, an enlargement from a quarter-plate on Ilford rapid paper. Dr. W. W. J. NICHOL then proceeded with his lecture and demonstration on his *Kallitype*. He traced the history of "iron" printing from 1840 up to his latest development of the "Kallitype" process, explaining how various colours were produced, concluding by developing several prints he had made that day. In response to questions from the President and members, Dr. Nichols stated that the "Kallitype" paper kept well, that it was more sensitive than silver paper, that it was cheap, and easy to use compared with bromide or platinotype. PROFESSOR ALLEN spoke most highly of "Kallitype" paper.

Nottinghamshire Amateur Photographic Association.—March 9.—The Rev. Beckton exhibited a set of slides taken by him in Switzerland. The pictures were supplemented by a description by Mr. Beckton, which greatly added to their interest.

Oxford Photographic Society.—March 17.—Mr. PAUL LANGE will give his *Norway* lecture in the new theatre in aid of the Radcliffe Infirmary Building Fund. The Rev. Dr. Bright, Master of University College, will take the chair. Mr. E. A. Ryman-Hall, and Mr. A. F. Stanley Kent, M.A., Magdalen College, will act as delegates of this Society on the "affiliation" scheme.

Rotherham Photographic Society.—March 1, Dr. Baldwin (President) in the chair.—A discussion on printing processes, as illustrated in the recent Exhibition, took place. It was pointed out that neither carbon nor the platinotype prints had been received from members, although there were some choice examples of both methods kindly lent by outsiders. The Question Box was also the means of an interchange of opinions on toning, washing, and mounting albumenised silver prints. For the benefit of new members it is intended to devote three or four extra nights to elementary subjects.

Sheffield Photographic Society.—March 1, Mr. Chesterman in the chair.—Some slides of hand-camera work caused a very warm and earnest discussion whether a good and artistic picture could be taken with the hand camera, and the uses and abuses of that class of camera.

Edinburgh Photographic Society.—March 2, Mr. H. J. Blanc (President) in the chair.—Mr. F. C. OLIPHANT read a paper on *Eastern Europe from a Photographic Point of View*, in which he detailed his experiences in south-eastern Russia. He mentioned that it was of little use, indeed dangerous, to photograph there without permission from the higher authorities, and that was a most difficult thing to obtain. For the guidance of future workers in that region, he stated that so-called detective cameras were of little use. He had found a compact hand camera to be best suited for the purpose. A report by the Special Committee appointed to look out for new premises for the Society was then submitted. It was to the effect that they had finally settled upon a house in 36, North Castle-street, fully detailed plans of which, prepared by Mr. Blanc, being exhibited, smaller scale plans of the same being also issued to each member with the billet calling the meeting. The first flat, after the necessary structural alterations have been made, shows a hall forty-two feet by sixteen feet, which will be ample accommodation for the monthly meetings, and which may also be used as library and reading room during the day. This might also be let to other societies for evening meetings. There are also on this flat another room, which may be used as lecturers' ante-rooms, committee-room, writing room, for members' use, as well as a kitchen and other conveniences. The second floor has a room with oriel window, which it is proposed to make into a dark room with good accommodation for workers for changing plates or arrangement, and a larger one which may be used as a smoking-room, as well as a much larger one, and another which, if not needed for the work of the Society, could be let to a suitable tenant. The attic flat it is proposed to appropriate as a dwelling for the caretaker. The Committee's report goes on to state the advantages to members not having home accommodation, and other matters, such as the cost and prospects of return. The cost of original purchase and alterations are estimated at slightly over 1000*l*. The ready money necessary has been raised by 50 debentures, held by members, no one holding more than three, the Society retaining the right to buy these up from time to time as its funds will admit. There is also a proposal before the Society for the formation of a lantern club, to be restricted to its members, for the discussion of questions relating to optical projection, the making and exchange of slides and similar matters. The contributions to the Maddox Fund at the last popular meeting amounted to 5*l*.

Glasgow Photographic Association.—February 25, Mr. William Lang, jun., F.C.S. (President), in the chair.—The lecturer for the evening was Mr. A. Lawrence Mitton, who showed a large series of transparencies to illustrate his subject, *A Chat about Modern Painters*, which was treated in an instructive and interesting manner. Slides were shown from the works of Wilkie, Turner, Landseer, Maclise, Tadema, Leighton, Meissonier, Millet, &c. March 3, Three new members were elected, viz., Messrs. G. C. Gibson, John Annan, and Rev. A. W. Russell, M.A. Mr. JOHN ANNAN read a paper on *The Position of Photography in relation to Beauty and Utility*. The reading of the paper was followed by an animated discussion. One of Mr. Dallmeyer's new Telephotographic lenses mounted in aluminium, and a new hand camera, the "Flying Scud," with a novel folding arrangement, were shown. A series of transparencies by Mr. Lynch's Ives-Hay collodio-bromide plates was passed through Mr. Sweaty's lantern.

Dundee and East of Scotland Photographic Association.—March 3, Mr. J. D. Gibson (President) in the chair.—A lantern slide competition among the members of the Society was entered upon. Eleven competitors took part in it, each of whom exhibited a set of six slides. With one or two exceptions the views were of an exceptionally high standard. The results were declared as follows:—1, Mr. J. D. Gibson; 2, Mr. J. R. Stewart; 3, Mr. V. C. Baird. The latter half of the evening was taken up with the exhibition of a large number of slides illustrating the uses of a hand camera, which had been lent to the Association by Mr. A. R. Dresser, of London. The set included some fine sea subjects, taken chiefly on the south coast of England, and also some very pretty street views in Brittany and Holland.

The Photographic Society of Philadelphia.—February 10, the President, Mr. John G. Bullock, in the chair.—Dr. ELLERSLIE WALLACE read a paper on *The Fading of Silver Prints*. Dr. MITCHELL took exception to the reader's statement in regard to gelatine as a mountant. He was not quite so ready to ascribe the fading of silver prints to this source. It seemed to him that if gelatine possessed this property it would affect the integrity of every emulsion that was made, not only for negative plates, but also the different forms of gelatine emulsions now prepared for aristotypes. If the mount was made with a common grade of gelatines there might be injurious chemical substances in it, because it was well known that acid was used as a necessary adjunct in its preparation; but he very much doubted whether good gelatine would have the effect ascribed to it by Dr. Wallace. Another probable cause for the fading of prints was that they were not fixed long enough. It was much more important than washing. It was a very common habit to take a negative out of the fixing bath as soon as the colour disappeared, thinking that it was fixed, but this was a wrong impression. It should either be allowed to remain five or ten minutes longer in the hypo, or be entirely transferred to a fresh fixing bath. He fully believed a good deal of the trouble in regard to the permanency of silver prints was due to insufficient fixing. He would add, in conclusion, that he agreed with Dr. Wallace in regard to the injurious effect of extensive washing. It tended to destroy the character of the image, and also probably affected the permanency of the photograph. Mr. CARBUTT stated that during the Centennial he had quite a number of Irish views, the majority of which he mounted on thin glass plates with gelatine. It struck him that possibly the gelatine might absorb moisture, so he varnished the plates with collodion. When he last saw them they were unchanged. He had pictures, purchased in Paris in 1862, which, when last seen, bore no traces of fading. Some of his own make, made in Chicago in 1862 or 1863, were just as fresh now as the day they were made—made, too, in the ordinary routine of gallery work, using carefully the best materials to be had. Dr. WALLACE asked whether the gelatine contained any glycerine. In the experiment he referred to the gelatine contained a proportion of glycerine. Mr. CARBUTT said he used no glycerine, only a plain solution of Nelson's gelatine. Mr. C. W. MILLER called the attention of the members to Mr. A. L. Henderson's communication in the *Bulletin* of the French Society, wherein he stated that it was impossible to make a good emulsion with nitrate of silver and gelatine *prepared together*. During the process the nitrate of silver and gelatine should never be allowed to come together, otherwise green and red fog would inevitably ensue. This does not refer to boiled emulsion, but digestion in twenty-four hours. Mr. CARBUTT said he had had a little experience in making emulsions, and did not agree with Mr. Henderson's views. He had tried his method, and found it impossible to make a rapid emulsion with it. A good emulsion could be made with the nitrate of silver in contact with gelatine, and he had accomplished it in that way. Mr. J. F. SACHSE, as announced, exhibited specimens of work done with the new photo-tele-objective of Dr. Adolph Miethe, of Berlin, and read an explanatory paper in connexion therewith. Mr. CHEYNEY stated that he did not see how it differed from the regular Galilean telescope, and that there seemed to be a strange coincidence in the fact that Mr. Knipe, of Queen & Co., had been using this very identical thing for the purpose of having a variable focus for lantern objectives. It had also been used in the microscope as an amplifier. He did not see that there was anything new about it, except to apply it to photographic purposes. Mr. LUDEKE exhibited a model he had made of Dr. Miethe's combination, together with a print from a negative made with it, showing the tower of the City Hall, taken from Washington Avenue, over a mile distant. The lens used for the positive was a six-inch portrait lens, and the concave was only two inches—in fact, was from an ordinary opera glass. The result was very satisfactory, and a practical illustration on the ground glass, using a gas jet and bracket as a focal point, was of great interest to all the members present, the camera exhibiting two pictures, one with the ordinary lens, and the other with the new combination lenses. The difference was very apparent.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

RATIO OF GRADATION.

To the EDITOR.

SIR,—In the article on the Hurter & Driffield investigations which appeared in last week's BRITISH JOURNAL OF PHOTOGRAPHY, Mr. Bolton mentioned a point of the greatest importance in theoretical questions which does not yet appear to have been satisfactorily settled. The true relation between the amount of reduced silver in any part of a negative, and the opacity produced by it, is still, to some extent, uncertain. Messrs. Hurter & Driffield, in the original paper on *Photo-chemical Investigations*, explain their view of the matter in this manner:—If we have a number of films of equal density, each of which transmits a certain fraction of the light it is exposed to, say, $\frac{1}{2}$, then, if any number of such films are superposed, as each will transmit $\frac{1}{2}$ of the light it receives, the total result, when there are n such films, will be that the amount of light which passes through all will be $(\frac{1}{2})^n$ of the original intensity, so that n, the number of films, is also the logarithm of the transparency to

the base $\frac{1}{2}$, or, multiplied by the proper modulus, to any other base.* The ratios of the logarithms of transparencies are thus shown to correspond to the number of superposed films, each of which contains the same quantity of reduced silver; and it follows, therefore, that they are proportional to the amount of silver per unit area; but the *total thickness* of film in this case *varies*, and in the same proportion as the different values of n. It has not been proved that the same law applies when, as in a photographic plate, the thickness of film is always the same, and the silver, whether much or little, always contained in the same space. Messrs. Hurter & Driffield merely write: "The reduction of the intensity is, of course, due to the black particles, and depends simply upon the number of them which are interposed per unit of area." But that does not appear to be so entirely a matter of course as is here implied; the positions of the particles of silver may have to be taken into consideration. Carried to the absurd, we should expect to find, on these principles, that a sheet of perforated zinc transmitted no more light than a thinner unbroken piece of the same metal, if of equal size and the same weight, as the number of molecules of zinc per unit of area of each piece would be identical. Messrs. Hurter & Driffield's principles will, no doubt, be found correct when the thickness of film is large compared with the size of the grains of silver; but it must be remembered that, in most rapid plates, the grains are of appreciable size. If we take an extreme case, and suppose a film of only the same thickness as the diameter of one grain, it is evident that there could then be no overlapping, so that every grain would obstruct the same amount of light, and the opacity (using the expression, however, in a different sense to that adopted by Messrs. Hurter & Driffield) would be proportional to the quantity of silver present. The transparency to one unit of light would be $1-a$, a representing the amount of light obstructed, and being always proportional to the amount of silver.

Mr. Plener, in one of an unfinished series of articles on subjects of this nature (rather marred by confusion of arithmetical and geometrical progressions) in the *Photographic News* of 1882, when considering the principles involved in the preparation of sensitometer screens, gave a formula based on the above which, with some modification, may be applied to the case of photographic plates. Simplifying his method a little, the film may be considered as consisting of n imaginary layers, each of the thickness of one of the grains of silver, and each passing $1-a$ of the light received. The transparency of the actual film will then be a fraction equal to $(1-a)^n$ (this is supposing the grains to be all of equal size and evenly distributed), a varying in the same proportion as the total amount of silver present. Messrs. Hurter & Driffield's principles might be represented by the same formula, treating n as the variable quantity. In either case n would represent the thickness of film; but if we take a transparency of $(1-a)^n$ as a standard, the effect of doubling the amount of silver, for example, would by one system give $(1-2a)^n$, and by the other $(1-a)^{2n}$. Now, when n is very large, the values of these two formula will be practically identical, and, remembering that $n=\frac{\text{thickness of film}}{\text{diameter of grain}}$, it appears to have been large in all the experiments by which Messrs. Hurter & Driffield tested the corrected of their views. For the experiment with Indian ink, a cell was employed, the width of which was probably many times greater than the thickness of a dry gelatine film; and in all their more important experimental work they used Chapman's *slow* plates, in which the silver would no doubt be in a very finely divided state, and these plates were specially prepared, "every care being taken to secure a *thick* and even film." Captain Abney, in 1889, performed some experiments in this direction, and I find his results in a trial with Indian ink in no way support Messrs. Hurter & Driffield's views; while an experiment with dried gelatine films containing known quantities of silver certainly agrees fairly well with them in the middle numbers, but is quite out at both ends of the series.

Dr. Eder gives ·003 mm. as the diameter of the grains of Ag Br in rapid emulsion, and the average thickness of film in a gelatine plate may, perhaps, be taken as about ·03 mm. These are not extreme figures, and many instantaneous plates probably have coarser grains contained in much thinner films; but, if we use these estimates, we have a ratio of 1:10, so that $n=10$ and that value of n will lead to very different results if the formula derived from Mr. Plener's article be followed to those which would be shown by that of Messrs. Hurter & Driffield. If we start with such a proportion of silver that one-tenth the thickness of film would obstruct ·01 of the light, then the total transparency would be $\cdot 99^{10}$—·9044; and, taking that as representing the effect of one unit of silver by either formula, the accompanying table will show the results of increasing the amount:—

Amount of Silver.	Transparencies.	
	Plener.	Hurter & Driffield.
1	·9044	·9044
10	·3487	·3660
20	·1074	·1340
40	·0061	·0179
50	·00098	·00658

It will be seen that increasing the silver ten times—which gives a transparency of about $\frac{1}{3}$—has produced but little difference between the columns, but they then gradually disagree, till in the great densities given by fifty times the silver, if the first column is correct, the other shows more than six times too great transparency. Eighty units of silver would show a difference of three thousand times, but the densities would then be far beyond anything we have to consider in photography.

The formula I have described appears to be more probably correct than that of Messrs. Hurter & Driffield, but still there are several reasons why it is not altogether to be depended on. I have treated the grains of silver as being all of the same size and equally distributed through the film, but these conditions are, of course, not really fulfilled. In all emulsions the fineness of grain varies considerably (the more the better), and finely divided matter gives much greater opacity than an equal quantity in a coarser state. Then the bromide of silver always settles down more or less in coating the plate, especially in the case of rapid emulsions. The coarser and more sensitive grains sink to the bottom, while the finer, remaining on the surface, will be the first attacked both by light and by the developer. The thickness of the film, too, varies after development, the more transparent parts being depressed. All these matters lead to much uncertainty in any attempt to find a formula which may be depended on. So far as they result in greater concentration of the deposit, the result would be similar to taking a smaller value for n, but the whole is so doubtful that there seems little hope of finding a really correct formula by which the amount of silver may be calculated from the transparency, or *vice versâ*, especially in rapid plates. Experiments may perhaps lead to the discovery of a satisfactory empirical formula, and, in fact, that of Captain Abney agrees very closely with observed results except in the higher densities.

Messrs. Hurter & Driffield's method is, no doubt, practically right in regard to very slow plates, and their "correct formula," which depends upon the truth of it, is, at any rate, in that case probably quite trustworthy. Even if its application must be limited to the case of slow plates, this "correct formula" may be of much value in future investigations, and probably in many scientific uses of photography.—I am, yours, &c.,

H. J. Channon.

Woodlands, Lewisham, S.E., March 7, 1892.

* *Opacity*, as defined by Messrs. Hurter & Driffield, is merely the reciprocal of *transparency*, and represented by changing the signs of the logarithms, which would otherwise be negatived by the ordinary tables.

SOCIETY FOR KENSINGTON AND BAYSWATER.

To the Editor.

Sir,—Owing to the West London Photographic Society having moved its headquarters from Hammersmith to Chiswick, the large district comprising Bayswater, Hammersmith, Kensington, and Notting Hill is now left without a society. Within this large area it is thought there are many photographers, both amateur and professional, who would benefit by a society being formed in their midst, so a few gentlemen interested in the subject met last week, and resolved to call a meeting for that purpose. It will be held at the Horbury Rooms, Kensington Park-road (close to Notting Hill-gate station, on the Metropolitan Railway), on Monday, the 21st inst., at 8.30 p.m., and all gentlemen interested in the matter are invited to attend. Those unable to attend, but willing to join in the movement, are requested to send in their names to me before the date of the meeting.—I am, yours, &c.,

Charles W. Brumwell,
Secretary pro tem.

7, *Lower-terrace, Notting Hill, W.*

LOSS OF DENSITY IN FIXING.

To the Editor.

Sir,—Please allow me a few words more on "loss of density in fixing." You say at the end of your notice, p. 130, that the so-called loss of density in the fixing bath is due to under-development or under-exposure. Exactly what I said—under-development principally, however. Now, ask the manufacturers to say on labels that their plates should be developed rather more or less than others, or something to that effect, and all will be right.

When I said it would be better for the professional or amateur wanting to make a trial of the plates, and in the end to the manufacturer, I meant to prevent the discouragement to the amateur and if you want the renewal of a trial to the professional. The first one may give that brand of plates up at once, as not sensitive enough; and the second one (professional), if more conscientious, may try more exposures and increased density in development, or may give up without further trials.

I may be mistaken in the origin of the reason why, but here is one of my experiences, repeated several times. I took a negative with rapid exposure, and developed it fully, and even more than I usually do, judging by transparency and by the back of negative; and, after fixing, the negative was not fit to print from, being too thin.

Allow me to tell you my way of judging when a negative is fully developed, and perhaps you will see that the iodide of silver or the thickness of the film play a lesser part in the judgment, at least with me, as to when I should stop the development or go further, than you may think. When I put the plate in the developer I watch the image, first as it comes on the face of the plate, and then by transparency, until it gets the intensity it should have when finished; then I watch it from the back by the colour it gets (not the image, which I cannot see by reflected light, of course). From first white it turns slightly grey, and, as this colour

deepens, I consider the negative well done when this grey is pretty dark; say, about the colour of bright old silver. Then I stop, and wash and fix, and the result is, about ninety-nine times out of a hundred, good.

This for my regular brand of plates, W. & W.'s. Some other plates may work the same, but certainly some do not; and, to get a good printing negative, I have to watch the back, on some of those, get to a much darker grey, edging on black; and, as to transparency, not be able to know what is on the plate. However, result: a very good negative to print from.

Loss in hypo. or what? Development has certainly to be carried on further than with other plates. If the manufacturer can let us know about it beforehand, some trouble can be saved, and probably some more trade to some of them.—I am, yours, &c., A. LEVY.

4, *Avenue Pinel, Asnières (Seine), February* 29, 1892.

MR. COLES AND MR. HOWSON.

To the EDITOR.

SIR,—As Mr. Howson refrained last week from mentioning any evidence in support of the accusation made against me of misrepresenting him, I can only assume none to be forthcoming and the charge to be considered as withdrawn.—I am, yours, &c., WILLIAM COLES.

Watford, March 7, 1892.

THE TRUE POSITION OF THE PHOTOGRAPHER IN THE ART WORLD.

To the EDITOR.

SIR,—I see that my letter of January 8 did not altogether convey the impression to the minds of some of your readers that I expected or intended, and, if I might be allowed to further introduce myself, no doubt they will become better acquainted with me. My connexion and association with photography, extending over a period of nearly twenty years, entitles me, perhaps, to as much recognition in your columns as the majority of your readers; nevertheless, my experience as an artist constitutes me a decided outsider, as far as some of the sentiments expressed therein are concerned.

Perhaps it is due to my training as an artist that I have been led in my own mind to make so pronounced a distinction between the word Artist and the word Photographer that I took it for granted the two would not in any way become confounded. In this I am perhaps to blame, as it is now evident that a wide and varied construction is put on the word Artist among your readers. In justice to that portion of your readers I represent, I feel bound to give my own definition of it. I must admit I find some difficulty in approaching this subject without leaving myself open to misconstruction and giving offence where least intended, and, did I not feel confident that I should meet with the support of higher intelligence among your readers than my own, I should not feel competent to come forward.

Before going further, I might point out that my letter was in the main a protest against a one-sided controversy, in which the artist was not up to them represented, and only appeared to be recognised as an opposing party, and that I made little or no attempt at argument under the heading you kindly supplied; and, while claiming to be recognised as a supporter of the interests of science and art, I most respectfully decline to participate in any contention that appears to me unworthy of the name.

Vague as the word Artist may appear to be to some, I have always regarded it as belonging to that school whose course of training is laid down on the same lines as those adopted by the so-called artist-painter, whatever branch may be ultimately intended; whether it be sculpture, painting, engraving, designing, &c., it must necessarily be of a creative nature.

An artist may take up photography and become an artist in photography (in connexion with it), but cannot obtain that position without first proving himself an artist outside of it, and altogether independent of it, for the simple reason, and it is an admitted fact, that by resorting to mechanical means he is digressing from the principles upon which he became an artist; hence all the more reason for efficiency beforehand, and under which circumstances he must revert as often as possible to the training he commenced with to keep him up to his standard merit and prevent retrogression. It cannot be denied there is good scope for the exercise of artistic intelligence in connexion with photography; nevertheless, its advantages must be realised to be properly appreciated. I cannot admit of any person becoming an artist on his own assumption—there must be some tangible proof of qualification; otherwise, where indeed must the line be drawn? I maintain that the trained artist is the fit and proper person to carry out the work of the scientist in photography, and so supply what the intelligent patron will demand, the combination of science and art.

The scientist does not claim perfection in photography from an artistic point of view, nor does the artist take credit to himself for the scientific part—only for what he is able to supply. We all take up photography more or less on sufferance, and we have no right to abuse our privileges. What I strongly condemn and refuse to participate in are the insults that are piled upon the artist who prefers to dispense with all mechanical means in bringing about his desired result.

What must our esteemed brother artists in other capacities think of the intelligence or sincerity of a man claiming to be an artist, who will compare the mere brushes and palette of an artist with the camera and lens of a photographer, and place them on an equality as regards the part they play in the production of the work? I would ask such, are they under the impression that brushes can be bought guaranteed to paint, or form pictures of given dimensions, the same as they can buy lenses, and do they suppose that brushes and palette can be so set together that an artist can go away and leave them doing the work, come back and apply a liquid to his canvas, and find the picture complete, and not always be sure, unless he has correctly numbered his canvas, what the subject of his picture was going to be, or which was the right end up?

To designate a man 'a wielder of the brush' is to imply that he uses the brush mechanically, as he might do in painting a house, &c. The use of the brush does not make a man an artist any more than the use of the camera and lens will ever make a photographer one. If there is nothing in a name, why are photographers so anxious to prove their claim to the title of artist, and why take trouble to analyse the word, and show that it means nothing in particular? Or why investigate ancient history to show that artists were thought nothing of before the world was barely civilised or educated? And is it not as mean as it is ridiculous to compare a photograph with a water-colour drawing? If the photograph was the best specimen ever produced, and the water-colour drawing the worst, the one is still a mechanical production, and the other a work of art. The photographer will take credit where he is not entitled to it, or where his intelligence is not in any way responsible; the actual creation of the desired object is the work of nature.

A photograph may be compared to a plant; the dry plates are like the virgin soil, the ground has been prepared, the exposure is given, the seed is set, the latent image is there, it is watered, it is nourished, the developer is applied; now notice how the cold weather retards its growth, notice how the sunshine accelerates its development, soon a plant in full bloom appears on the surface.

But suppose you have a friend who has made, by his own hand, a beautiful imitation in wax of the same kind of plant, and he shows it to you, would you have the impertinence to tell him you had made one "that would beat that into a cocked hat," and rush off and fetch the one you had grown in your garden? Does this illustration not give you some notion of the meaning of the word Art?

If the photographer cannot claim to have contributed something towards the advancement of the science of photography, beyond amusing himself with it, or living on it as though it were specially designed for his benefit, and if he refuses to qualify himself as an artist, then he is nothing more than a mechanical photographic practitioner; and, if I am asked the question, I should say, these are the men who have benefited most by photography, and hang on to the name of science and art for protection, while they insult people who have earned a superior position.—I am, yours, &c.,

ARTIST WITH BRUSH, PENCIL, AND CAMERA.

45 *Wynford Street, Eccles New Road, Manchester.*

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Wanted, 7½×5 or larger camera complete. Exchange *Gazettes of the World* (Fullarton's), thirty-two parts, complete, uncut. Address, ROBERT MCCONCHIE, Kirkcudbright.

Pair of backgrounds in flatted oils, on linen, 8 ft.×7 ft. 6 in. Exchange for good violin. Photographs forwarded. Address, W. HARE, Windsor Studio, Sutton, Surrey.

Will exchange three-quarter-plate rapid portrait lens by Spicer Brothers for half-plate rapid rectilinear or Euryscope lens by a good maker.—Address, P. PILCHER, Photographer, Dover.

I will exchange Cassell's *Technical Educator*, clean and perfect, for half-plate combination rectigraph lens, or Booth's mitre-cutting machine. Address, M., 3, Nightingale-terrace, Sutton, Surrey.

Forty-one numbers of the *Photographic World*, commencing with No. 4, for the *Ilford Manual and Robinson's Picture Making by Photography*.—Address, H. O. THOMPSON, 45, Gloucester-road, Newcastle-on-Tyne.

Seven years' BRITISH JOURNAL OF PHOTOGRAPHY, Ross's 10×8 doublet, ditto whole-plate doublet, backgrounds, Seaves's, rustic bridge, half-plate portrait lens, strong tripod stand; wanted, 12×10 landscape camera, with double slides, also changing-back chair.—Address, W. HASSETT, Stoke-road, Guildford.

Will exchange a very light half-plate camera, three double slides, rapid rectilinear lens, Thornton-Pickard shutter, stand, whole weighing under nine pounds, nearly new, cost 8*l.* 15*s.*; also a quarter-plate Lancaster's International, three double metal slides, lens, shutter, stand, and case, complete, cost altogether 3*l.* 15*s.*, with an extra double slide and screen, for a Ross's Cabinet portrait lens.—Address, MAFIN, The Avenue, St. Margaret's, Twickenham.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

PHOTOGRAPHS REGISTERED:

W. M. Ashman, Bath.—*Two portraits of the Rev. Francis Edward Murphy.*

HENRY HILL.—437½ grains.

E. MARTIN.—From the description given, we should think the article would answer well.

A. J. STATHAM (King's College).—It is a fine specimen of the ordinary Talbotype negative taken in the camera.

C. W. GASKELL.—The image is formed of metallic silver. It is probably as permanent as any other process.

M. B.—We are unacquainted with the first firm yon name, and of the other we know nothing to their disadvantage.

H. MOREL.—Messrs. Tunny of Edinburgh, Martin of New Southgate, Watson of Hull, and others, undertake ceramic work.

SINED.—So far as we are aware, Mr. J. J. Atkinson, of Liverpool, is the sole agent for Seavey's backgrounds in this country.

DOUBTFUL.—1. *F*-12 to *f*-15. 2. As far from the lens as will permit the corners to be touched. 3. Yes. 4. You must ascertain by experiment.

P. NOLAN.—For copying engravings, extra rapid plates are of no advantage—quite the reverse. For this work use slow plates, so as to obtain vigour, with clear lines. Plates specially made for copying are the best for the purpose.

T. MATHIAS asks: "Will you kindly tell me if there is anything that I can darken my goat-skin rug with? It comes out too white in the photograph."—Try the effect of immersing the rug in a dilute solution of bichromate of potash, and dry in the sun.

E. C. W.—Methylated spirit of the "old sort" can still be obtained for manufacturing purposes, but only in wholesale quantities, and then by giving a heavy bond to the Excise authorities that it will only be used for such purposes. As you say, the thing is a nuisance.

W. DAVIS.—1. Settle upon the lantern that has the right inch condenser, and use the cabinet portrait lens for enlarging with. 2. The wide-angle single lens is not suitable for architectural subjects, though it is excellent for landscapes when a wide angle has to be embraced.

GEO. HENRY RUTTER.—1. We believe that the object of the solution is simply to "desensitise" the unaltered bromide, and thus no alteration in its appearance would take place. 2. Obviously, so soon as it fails to produce the foregoing effect. 3. Quite feasible, we should think.

G. F. F.—The various proportions of the constituents of the solution could only be determined by the volumetric method. As you confess your total ignorance of that system, we fear that a description of it, besides occupying far more space than we could spare, would not be intelligible to you. Better consult some work on volumetric analysis. The impurities from the bath may be removed by kaolin.

ECHO.—The "figures on the stops" indicate that the aperture of the diaphragm is a given fraction of the focal length of the lens. Such a lens would certainly "be useful for views." You had better study the elements of photographic optics, as you appear to be ignorant of the use of stops and the various forms of lenses. To our knowledge, there is no law prohibiting you from taking views of London on Sunday.

W. TATE says "he has a large copying camera, made many years ago, with a mackintosh cloth bellows, and now the folds, when pressed together for a short time, stick. They did not do this until quite recently. He wishes to know the cause and the remedy?"—The cause is that the rubber is becoming perished, which it is liable to do with age. The sticking may be prevented, in a great measure, by frequently rubbing the folds over with French chalk.

W. R. L. is desirous of forming an amateur society in his district, and asks how to proceed, and what is the usual subscription?—The usual way is to call a preliminary meeting of those in favour of the scheme, and at that draw out and frame rules; then call a general meeting, and submit them for confirmation or alteration, and appoint officers. The subscription to different societies varies from five shillings a year upwards. About half a guinea is the general sum.

A. R. J. asks "if he sends some negatives by rail and they get broken in transit, and they are insured for a certain amount, can he recover that amount in full?"—Yes, certainly, provided he can show that the negatives were of the actual value for which they were insured. He can only recover the real value of them, whatever that may be, and not any fancy sum for which they may have been insured. It has been decided, in a case for compensation, that the value of negatives that were broken was little more than that of the glass and the materials upon it. That was some years ago.

A. P. would be glad to know if there is anything beside brown glue suitable for sticking the backs on to opalines, as he finds it is liable to discolour the photo where it touches; also, if put in a sunny window, the backs frequently come off. As A. P. has a large quantity of opalines to make, he would be obliged by any suggestions.—Any adhesive that will stick the backs on will answer the purpose as well as brown glue. If this discolours the picture, a pale gelatine might be employed. Possibly the glue was applied too thick, and that was the cause of its becoming detached. As we have said before, anything may be used.

T. M. BRAUND and others.—Received, with thanks.

C. WARD.—1. The difficulties you find in working the carbon process may possibly be accounted for by a careful perusal of an article on another page. 2. It is quite a mistake on your part to imagine that gelatine negatives are not suitable for producing good prints from the carbon process. 3. What is sold as transfer collodion will answer for coating the glass with, but it should be thinned down a little with ether and alcohol; methylated, if strong, will do. 4. If the coating of the flexible temporary support comes away with the print, it shows one of two things—either it was not sufficiently waxed, or too hot water was used for developing.

S. A. E. writes he has tried all the processes for making half-tone process blocks that have been published, and finds that none of them will give good results. He adds that he believes what has been published is misleading. We disagree entirely with our correspondent on the last remark, because it is not correct as to several methods described in our back volumes. The mere reading of the details of any process, and working by any particular formula, will not give the practical experience always necessary to produce good results. A business, and a somewhat intricate one, too, cannot be learnt without a prolonged experience. Some of those who are most proficient with this class of work have spent years in acquiring their skill and experience. With process blocks, as with every other branch of industry, there is much to be learnt before uniformly perfect results are obtained.

D. DIXON writes: "I often see recommended as a mounting solution one of gelatine, water, and methylated spirit. I have tried making it several times, but always failed, although I have kept strictly to the formula and used the strongest gelatine I could get—Coignet's Gold Medal, to wit. My difficulty is this. As soon as I add the spirit, a hard coagulated mass separates, and leaves the solvents clear, and no amount of heat and stirring will make them combine. Can you enlighten me?"—The reason is that the spirit has caused a precipitation of the gelatine, and our correspondent has used about the most unsuitable kind for the purpose. To make a solution of gelatine containing a large proportion of spirit, a very soluble kind should be employed, such as, say, Nelson's "No. 2 soluble." With this a tolerably large quantity may be introduced without precipitation. The stronger and more insoluble the gelatine, the less the spirit that can be used without causing precipitation. With some of the commoner qualities of glue a solution may be made with nearly all spirit.

RECEIVED.—Several catalogues. These in our next.

THE PHOTOGRAPHIC CLUB.—March 16, *Shutters*, by Mr. A. S. Newman. 23, Last Lantern Night of the season. 30, Smoking Concert.

THE Council of the National Association of Professional Photographers requests that all photographers not yet enrolled as members will at once send their names and addresses for publication with the annual report and balance-sheet, about to be printed and circulated.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—March 17, Monthly Lantern Night. March 24, *Continental Photographic Institutions and their Influence*, Mr. W. H. Harrison. Mr. Warnerke will take the chair, and exhibit his lantern slides bearing on the subject. March 31, *A Short Demonstration of Photography on Wood*, Mr. W. S. Rawlings.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—Committees for the following objects, among others, have recently been appointed by the Council to consider whether any, and, if any, what explanatory additions should be appended to the report of the Committee of Standards of 1881, and to report upon the question of standards in subjects not dealt with by that Committee; to deal with all matters connected with the Museum; to consider the question of the recent Excise regulations relating to methylated spirit; and to consider the whole question of the Exhibition, and to report thereon to the Council.

"THE GREAT EARTHQUAKE IN JAPAN, 1891."—The work by Professors Milne and Burton on the terrible earthquake of last October is now in the hands of the public. It is printed in luxurious type, on paper of the finest quality, and illustrated by no less than twenty-nine large plates. Two months sufficed to collect materials for, illustrate, put into type, and bind it. Professor Milne's letterpress occupies ten pages. Into that short space he has compressed a great mass of information about earthquakes in general, and the Ai-Gi catastrophe in particular. With regard to the plates in the volume, they are photographs taken for the most part by Professor Burton, and reproduced by Mr. Ogawa. The scenes chosen convey a vivid idea of the great calamity and all its concomitant features. Accompanying each picture is a short description, which conveys all the information required for a full understanding of the scene.

*** *We have many articles and papers in type which we are obliged to hold over until the great pressure on our columns is relaxed. Several of our contributors and the secretaries of many societies will therefore understand from this the delay in the appearance of their communications.*

SPOTS ON ALBUMENISED PAPER PRINTS.

As our correspondence testifies, the complaints of spots on prints have become so unusually frequent that some discussion upon the subject may be of advantage. There is no doubt their occurrence can be traced to both general and local causes, some of the latter being particular instances of the former. First and foremost must be placed atmospheric phenomena, which, during the winter season, are provocative of so many evils, not the least being the tendency to induce the production of spots which, under ordinary or more general states of the weather, would not be seen. Albumenised paper, sensitised in the ordinary manner, is hygrometric to a very pronounced degree, and, the humidity of the air at this time of the year being at its maximum, the sensitised paper, though at the outset made perfectly dry, rapidly absorbs so much water that the slightest amount of foreign organic matter suffices to initiate reduction of the free surface nitrate, and so engender spots. This hygrometric condition is intensified by the fact of most albumenised paper being chlorised with ammonium compounds, with the result that the silver bath quickly becomes largely charged with nitrate of ammonia, a very deliquescent salt. Those who have found their prints suffer from an abnormal quantity of spots have noticed how, when they happen to have made a new floating bath, the spots for a time have diminished in frequency; there can be little doubt that this is owing to the absence of this deliquescent compound during the youth of the solution. If any one wish to ascertain whether his albumenised paper is prepared with chloride of ammonium, he need only drop upon the glossy surface a little solution of caustic soda or potassa, or of lime-water, and hold over the place a piece of red litmus paper, which will at once turn blue by the action of the ammonia thus liberated. It may easily happen that the ammonia can be detected by the sense of smell alone.

With these considerations before us, it is evident that the careful storage of paper before being placed in the printing frame will prevent the absorption of moisture. Similarly the periodical drying of the pads, decidedly advantageous for other reasons, will here also be beneficial. We may remark that the opposite extreme, the making the paper "bone dry" just before placing upon the negative will be the reverse of beneficial, as it is a well-established fact that over-dry paper will neither print nor tone satisfactorily. What is required is to prevent its arriving at the opposite extreme.

It is often felt necessary during dull weather, in the endeavour to utilise all available light, to print in the open air. *En passant*, we may say we consider this practice not to be so advantageous as is often supposed, for it must be a very defective covering that robs the light of even ten per cent. of its actinism. The result must naturally be the dropping down upon the print or the negative—the result would be the same in either case—of particles of injurious matter, soot, and, sometimes, metallic particles from sundry manufactories, the foggy atmosphere not permitting the quick deposition that would occur during dryer weather. It may be said such spots would readily be seen and removed; but, as a matter of fact, experience shows that such is not the case with at any rate the average printer; further, particles so minute as not to be noticed are quite capable of setting up a species of catalytic action resulting in a decidedly visible blemish.

If now we follow the subject to the consideration of particular and local causes, we find a multitude of sources, most of them well-known ones. Sufficient cannot be said about the need of care in the handling of hypo; unless it be used in a place far away from prints and printing, it is surprising how readily it gets into the air and injures the prints most seriously. We recently heard of an instance where the special care taken to avoid this evil had the very opposite effect to that intended. The principal of the establishment we refer to insisted upon all his printers wearing aprons in the interest of cleanliness. One of these *employés* was very careless, and an investigation into the cause of a serious number of spots and stains showed that he had allowed his apron to become almost saturated with hypo, particles of which were blown or brushed off on to the prints, and at other times his hands touching the deceptive protection became sullied with hypo, and prints were finger-marked in consequence.

One fertile source of spots must not be forgotten—the presence of particles of iron in the paper itself, or of injurious atoms in the albumen. At one time Rives paper was very liable to this defect, some paper being almost unusable; but now it is reduced to a minimum. We have seen spots, or rather stains, produced at this time of the year through incipient stains in an unvarnished negative. The silver had set off on to the gelatine, and produced markings which would rapidly ruin the negative. To print from an unvarnished negative when the atmosphere is at all humid is simply to invite the production of stains.

We may conclude our remarks by describing the cause of a large outbreak of spots which completely puzzled the head of a very large printing establishment. Small black spots of all shapes were present in such numbers as to be the cause of serious loss. It seemed impossible to find out their origin, until one day it was observed that the damaged prints (cabinet size) all were printed in some new frames that had been put into use. A further investigation showed that microscopically minute particles of brass, produced either in finishing off the frame or by the friction of the spring in opening and shutting the back, were readily discernible. A thorough cleansing of the frames, over all the surface and into the corners, was at

once carried out, and the evil was laid. So simple a cause had such widespread results that we deem it most useful to describe the occurrence, thinking the same may operate in other printing rooms. In any case, we trust the wide basis we have laid for tracing the cause of spots may be the means of enabling this evil to be mitigated, if not entirely banished.

PRINTING FROM DEFECTIVE NEGATIVES.*

One of the methods successfully applied in collodion days for thus strengthening weak negatives consisted in coating the reverse side of the glass with a mixture of honey (or glucose), gum, and bichromate of potash, and, after printing *through* the negative, dusting on powdered plumbago, which, adhering more readily to the unexposed portions than to those acted on more or less by light, formed a second negative image in one operation. This process, though simple enough in the hands of those who may be *au fait* in it, is not one that will recommend itself to the average photographer of to-day, more especially as its use in connexion with gelatine negatives is attended with serious inconveniences. But an efficient, if not a superior, substitute is to be found in collodion emulsion and the method of reversal.

It is a by no means difficult matter to coat the back of a negative with collodion or emulsion without injuring the front, nor is it beyond the range of possibility to develop an image on the reverse side without seriously endangering the original. But precisely the same result can be attained by forming the supplementary negative on a separate sheet of glass, so that, everything considered, that is the plan we counsel.

Take a plate prepared with bromised collodion emulsion—or, for that matter, a plate sensitised in the bath, so long as the collodion contains an iodide—and, placing it in the printing frame in contact with the *back* of the negative to be strengthened, expose to light through the film. Develop in the ordinary manner with alkaline pyro in any similar or "chemical" developer, only carrying the action much further than would be done if the image had to be fixed in the ordinary way; then, without fixing, flow over it a solution of "iron alum" (or potassio-ferric sulphate) of the strength of about fifty or sixty grains to the ounce. Under this treatment the positive image first developed will disappear, leaving a negative image composed of unreduced bromide of silver, in which, if the exposure and development have been right, the shadows will consist of perfectly bare glass. In order to arrive at this result, it is needful to give a full exposure and to carry the development to its fullest extent, even to fogging the plate.

It will be observed that the further the development is carried the more silver bromide will be reduced and subsequently removed by the ferric sulphate, and the thinner will be the image that remains. As it is essential that the shadows be quite clear, and as only a comparatively thin supplementary image is needed, it is advisable to over, rather than under, do this part of the business; indeed, although it is a somewhat delicate operation to make a perfectly satisfactory negative by this plan to print alone, for the purpose we have in view it is quite easy. With the class of negative it is intended to remedy the kind of image that is required as an auxiliary is one that, although generally thin, presents comparatively greater contrasts than would be desirable for printing alone; and these conditions are favoured rather than otherwise by carrying the first development to its fullest extent.

* Concluded from page 164.

In many instances the delicate image left by the iron solution will be dense enough without further treatment; but, if not, after washing thoroughly, let it be exposed for an instant to light and redeveloped by means of alkaline pyro, though in performing this operation it must still be borne in mind that a very thin deposit is what is required.

If the supplementary negative thus produced, after drying and varnishing, be placed in contact with the original, and made to "register," it will be surprising what an addition it makes to the apparent density as well as contrast, and what was previously a feeble image, with no printing value, will be found transformed into a strong and vigorous negative; but, if examined closely, the compound negative, however well the two portions may be "in register," will present a slightly "fuzzy" or indistinct appearance, as if wanting in sharpness, owing to the impossibility of getting every portion of the two images, as viewed by the eye, to coincide perfectly at the same time.

Some years ago a new style of portrait was introduced by a Russian artist named Denier, the effect of great softness and delicacy being obtained by forming a double image, one on either side of the glass; and these "Denier effects" all exhibit this peculiar indistinctness, which strikes the eye most at the first glance, and becomes less and less appreciable the more closely the picture is examined.

Such, too, is the effect produced by the supplementary negative used as we have described, consequent, no doubt, upon the slight overlapping of the two images in printing; but if the printing frame be set in motion during exposure, as already mentioned, the indistinctness entirely disappears, for the reason that the shadows of the second image, in consequence of the slight interval between the two, is constantly changing its position, and so vignetting itself into the original, with the result that, combined with perfect definition, there is the greatest delicacy and softness and an entire absence of any suspicion of "dodging."

It only remains to say that, in the case of hard negatives, the only difference in treatment is that the supplementary image is an under-exposed positive, instead of a negative, and is produced in the same manner, by simply printing direct from the original negative, and fixing instead of reversing. But it must be very thin indeed—more so, in fact, than in the case of the reversed negative image. What is wanted usually is simply a slight veil over the darker portions of the picture—the drapery or coat of a portrait, for instance—while the face and lighter portions remain clear glass. This end is gained by an exposure so short that the heavier portions only of the picture show any deposit, and that of the slightest, while the face remains expressionless and blank, except it be for a patch or two representing the shadows under the eyebrows, nose, and chin.

With a little ordinary care, any photographer, by following the instructions given, can easily apply the process we have indicated, and, though entirely unpossessed of any artistic skill in the direction of retouching, may produce really good results from negatives that would otherwise demand considerable attention at the hands of the retoucher.

Automatic Photography.—When shall we hear the last of the automatic photograph companies? Not, we imagine, until all the little assets remaining are swallowed up in legal matters. The most amusing part of the business, to all but the unfortunate shareholders, is that all connected with the affairs, from the aristocratic directors downwards, deny all responsibility in the matter, and any

knowledge of what was being done. The former, however, took pretty handsome fees, while others reaped a good profit. "Where ignorance is bliss ——"

Chicago.—Just now that British exhibitors, photographic and others, at the forthcoming Chicago Exhibition are considering their arrangements, the medical press generally are warning the public against the insanitary state of the city. It appears that in the year 1891 there were twenty thousand cases of typhoid fever, and that nearly two thousand of them terminated fatally. This is by no means a pleasant look-out for those who have arranged to visit the States during the show. Large numbers have done so, we believe, in parties such as those organized by the Polytechnic Institution.

Uniform Price of Specifications.—It will interest many of our readers to note that in future the specifications of patented inventions are to be issued at the uniform price of eighteen pence each, post free. Any specification in stock can be obtained from the Patent Office for that sum; and arrangements have been made with the Postmaster-General by which postal requests in the form of a postcard, price eightpence, will be on sale at each post-office, so that, the number and year of a particular patent being known, one may, by filling in the blank on the card, have a copy of the specification delivered by return of post without further expense or correspondence.

An Interesting Exhibition.—*A propos* of the above subject, the Assistant Secretary of the Photographic Society of Great Britain is at present organizing an exhibition of silver prints made thirty years, and upwards, ago. Such a collection of photographs cannot fail to be not only interesting, but also instructive. They will illustrate photography in the early days, as well as show that photographs on paper are not necessarily of the extremely fugitive character that some would lead us to imagine. The interest in the prints will be further enhanced if the exhibitors will attach to them such particulars as they possess. For example: process by which they were toned, strength of sensitising bath, character of negative, mountant used; also the conditions under which the prints have been kept, and any other information that can be supplied. From this Exhibition a lesson may be learnt.

Fading Silver Prints.—This subject formed the topic for discussion at a recent meeting of the Photographic Society of Philadelphia. The general opinion of the members appeared to be in perfect unison with that we have so often expressed in these columns, namely, that in the majority of cases the fading of silver pictures is more due to imperfect fixation than it is to insufficient washing; also that a prolonged washing, instead of conducing to permanence, actually militates against it. By long soaking in water the tones of the print become degraded, and, this being the case, it may fairly be assumed that, as vigour is lost, the stability of the image has been impaired. It must be borne in mind that the washing being effected in a short time does not imply that it is necessarily incomplete, any more than that a prolonged soaking ensures the removal of the hyposulphites. Prints can be as perfectly washed in an hour or two as they can in four-and-twenty hours.

The Exhibition in Paris.—Those of our readers who intend contributing to the International Exhibition of Photography to be held under the auspices of the Syndicated Corporation of Manufacturers of and Dealers in Photographic Specialities and Cameras in Paris, from April to September next, in the World's Exhibition (1889) Buildings, may obtain all particulars of Messrs. Marillier & Robelet, Civil Engineers, General Agents for Exhibitors, 42, Boulevard Bonne Nouvelle, Paris. The exhibits will be divided into eight groups as follows:—1. History of Photography. 2. Scientific Photography, Astronomy, Micrography, Photo-topography, Medical and Legal Photography. 3. Amateur Photography. 4. Professional Art Photography. 5. Industrial Photography, Photo-engraving, Photo-collography, Photo-lithography, Photoglypty, Photochromy, Stereoscopy, Photography on Silk, Glass, Linen, Enamel, China, Ivory, Wood, &c. 6. Chemical Products and Photographic Specialities, Collodion Films, Plates, Papers, Acids, Salts, Gelatines, &c. 7. Photographic Material, Optics, Mechanics, Cabinet Work, Leather Goods, Paper, Glass and Studio Requisites. 8. Trades connected with Photography.

New Societies.—At the present time there are something like 250 photographic societies in the United Kingdom. Are they all required? At one time there were but three in the metropolis—the Photographic Society, the North London, and the South London. Photographers, both professional and amateur, were more enthusiastic in the art in those days than they appear to be now, for although the two latter Societies met at the opposite ends of London—Walworth and Islington—the majority of the members of one were also members of the other, and what is more, as may be seen by reference to old volumes, they attended the meetings and took part in the discussions. Now it seems as if Societies must be brought to photographers instead of their going to them. In almost every district of London there are several small Societies where one would be ample, and indeed, more useful than several petty ones. Take the west of London, for example. Here is the well-established and energetic West London Photographic Society, the Ealing Society, the newly formed one at Chiswick, and now it is proposed to start a fourth at Notting Hill. Surely one, or, at most, two societies would be sufficient for this district, seeing the rail, bus, and tram facilities there are for reaching every part of it. Promoters of new Societies would do well to bear in mind the aphorism, "Union is strength," and that one good Society is better than half a dozen minor ones.

A "Tall" Business.—In reading the accounts of the "interviewer"—as well as the description of some establishments, even connected with photography—one is sometimes inclined to suspect that either the interviewer or the interviewed, or possibly both, have been somewhat "drawing the long bow." In the last issue of one of our monthly contemporaries is a description of Mr. W. J. Byrne's premises at Richmond, and, if this has not been the case in this instance, the gentleman is to be congratulated on the extent of his business. In the account it is said, "there were the negative rooms, with a stock of over two million negatives, a large proportion of them in 12×10 size and upwards." Now, two millions are expressed in two words, but some fail to realise what they actually mean. The writer had previously said that Mr. Byrne has been in business twenty years; consequently, discounting the "over," he must, on the average, have taken one hundred thousand negatives a year, or, omitting Sundays and holidays, when, of course, the studios are closed, an average of three hundred and twenty-five per day. The glass used for negatives of the smaller sizes weighs fifteen ounces per superficial foot; for larger sizes, particularly in the wet-collodion days, considerably more. As a large proportion of the negatives are 12×10, and larger, we will average them at 8×6, and the glass at one pound to the square foot; consequently two millions of such negatives would weigh nearly three hundred tons—equal to a train of thirty trucks of coal, weighing ten tons each. Every one knows the number of negatives put into stock does not represent the number of plates exposed, hence the cameras must have had a pretty busy time of it. As we have just remarked, if there has been no mistake, Mr. Byrne is to be congratulated on the extent of his business—due to the quality of the work he has issued.

TRIPLE LANTERN CONDENSERS.

Having for so many years advocated the employment of triple condensers for the lantern for certain purposes, it is gratifying to find that there is now a reasonable prospect of their being more generally adopted than they have hitherto been. For several weeks we have had lying beside us drawings, and a description of one which has been prepared by Mr. W. I. Chadwick, the nature of which will be ascertained from the following brief description. Interposed between the well-known plano-convex condensers and the light, is a meniscus rather smaller in diameter than the others, the peculiarity of its

mounting being such that the lens is very loosely placed in the cell, to permit of expansion under the great heat to which it is necessarily subjected, and also that, should a fracture occur, this lens can be instantly removed, and another put in its place; certainly a great convenience.

Mr. T. R. Dallmeyer has also been devoting his attention to this subject. In constructing condensers to be employed in conjunction with projecting lenses of definite focus, he has hitherto adopted the double form introduced by the late J. H. Dallmeyer, in which the lens nearest to the light is a plano-convex flint, and the second lens a bi-convex crown, with the deeper side towards the flint glass. By this combination the elder Dallmeyer obtained better results than had hitherto been obtained, both as regards correction for spherical aberration and a nearer approach to achromatism.

In view of the fact that it is a great convenience to employ a portion, at any rate, of one condenser perpetually, and to introduce a variable element to be used in conjunction with projecting lenses of various foci, Mr. T. R. Dallmeyer has constructed a triple condenser, in which he has utilised the principle, first laid down by Herschel, of employing two lenses of one kind of glass, with their radii so arranged that for parallel rays these two lenses by themselves are perfectly free from spherical aberration.

Counting from the light, the first lens is a concavo-convex meniscus, and the second an inverted crossed lens—that is to say, the deeper side of the crossed lens is farthest from the light.

If the light were a theoretical point and placed at the focus of these two lenses, for parallel rays, of course, a perfectly parallel beam would emerge from this portion of the condenser (a very useful and essential condition for experiments with polarised light). Close, again, to the second lens is inserted a third lens, or even combination, that has a focus for parallel rays of the desired length, suitable for the projecting lens that it is intended to employ, so that the first two elements may be considered a fixture, and the third lens may be of any chosen focus to suit the focal length of the projecting lens by simply interchanging one for another.

CAMERA CLUB CONFERENCE.

The Annual Conference of the Camera Club, which opens on Tuesday next in the rooms of the Society of Arts, under the presidency of Captain Abney, promises to be unusually attractive. On the afternoon of that day Messrs. Bothamley, Warnerke, Pringle, and W. Willis are to read papers on *Some Points in Connexion with Development, Chemigraphic Etching, Photography applied to Medical Research*, and *Recent Improvements in Platinotype* respectively. In the evening there will be a symposium on *Artificial Lighting in Photography*, in which Messrs. Vanderweyde and E. J. Humphery take part, while Mr. H. E. Armstrong, F.R.S., subsequently discourses on *The Theory of Development*. On Wednesday afternoon the programme leans largely to the art side of photography, Messrs. Henry Blackburn discoursing on *The Debt of Art to Photography*, H. H. Stannus on *The Uses of Photography to the Decorative Artist*, and H. P. Robinson on *Paradoxes of Art, Science, and Photography*. The President concludes the Conference with a paper on *Some Uses of Celluloid Films*.

The annual exhibition of members' work opens at the Camera Club on Monday evening; the annual dinner is to be held on Wednesday evening, and on the following night there will be an exhibition of lantern slides in the theatre of the Society of Arts.

The programme of papers arranged embraces subjects of interest to all sections of modern photographers, and a successful Conference should result. Admission to the meetings is free to all, no tickets being necessary. In face of this fact, combined with the excellence of the programme, to which so many able men are to contribute, we hope that the enterprise and liberality of the Camera Club will be rewarded by large attendances.

THE PLATINOTYPE PRINTING PROCESS.

[North London Photographic Society.]

The basis of this process, it is almost superfluous to say, is the elementary metal platinum, a member of a group known as the noble metals by reason of the difficulty attending their oxidation.

This property is enjoyed by some dozen metals in a marked degree and prominent among these are gold, iridium, osmium, palladium, and platinum, whose slight affinity for oxygen induces them to part company with combining bodies on very slight provocation; and thus it happens that the salts of platinum are reducible by inorganic as well as organic deoxidisers, the metal reappearing either in a soft spongy condition or as a finely divided black powder.

The metal is known to chemists by the symbol Pt and the equivalent 198, its specific gravity being 21·5.

It is found in alluvial deposits in little plates (hence its name) in Mexico and Brazil, but chiefly in Siberia, its export thus coming under the control of the Russian Government, who keep up the price by high export duties and monopolies to special metallurgical houses.

Hopes were at one time entertained that Australia would have furnished us with supplies, but, from the high price still maintained by the metal, these hopes, so far, are not realised.

The metal itself is silvery white, hard, and infusible, except in the oxyhydrogen flame or electric arc, but, being *malleable* at a high temperature, is used for making crucibles, retorts, ends of lightning conductors, &c., and is purchaseable in wire and sheet of any size or thickness.

The chief point of interest for photographers is that the metal is reducible from its salts by ferrous sulphate associated with potassic oxalate, and the high merit of the platinotype process consists in its so controlling the reactions that the reduction to the metallic state takes place in exact proportion to the exposure to light.

My admiration for the process is unqualified, unbounded, and I cheerfully concede all the advantages which are claimed for it, viz., superior sensibility to light, simplicity of manipulation, and absolute permanence.

1. It is three times as rapid as silver.

2. Pictures are developed instantaneously, fixed in half an hour, and washed in the same time.

3. The unoxidisability of the metal in the presence of air and moisture is an unquestionable guarantee of absolute permanence, and the inventor, Mr. Willis, is to be congratulated on having devised the prince of printing processes.

The method is as follows:—

1. Good strong paper is sized with gelatine, or starch, or arrowroot, the former tending to produce blue tones, the latter brown.

2. Paper so sized and dried is coated with a mixture of ferric oxalate and chloroplatinite of potassium, dried and exposed to light.

3. During the exposure the ferric salt becomes reduced to the ferrous state with the evolution of carbonic acid.

4. The ferrous salt thus produced in molecular contact with the platinum salt becomes the active agent in precipitating the platinum black, which is really the metal itself in a fine state of division.

5. The unaltered mixture of platinic and ferric salts is removed by immediate immersion in dilute hydrochloric acid, and, assuming the exposure to have taken place under a negative, the picture is now practically finished.

6. To ensure the complete removal of the iron salt, the immersion in hydrochloric acid is made three times, and for ten minutes in each dish.

7. After the last immersion the prints are copiously washed in a running stream of water for not less than half an hour, and then blotted off and dried.

I have thus briefly rehearsed the process as conducted at my own printing works at New Southgate, producing such results as I have the pleasure of exhibiting this evening.

It will not unnaturally be asked on what does success in this process mainly depend? Correct exposure in the printing frame is, of course, very important, but it is not a *sine-quâ-non*, since over or under-exposure may be compensated for in development; but, to secure high finish and delicate purity of whites, the paper should be recently prepared, and, above all things, be kept, before, during, and after exposure, absolutely dry.

To this end advantage is taken of the strong affinity of chloride of calcium for water. Asbestos is saturated with chloride of calcium and dried at a red heat, and this preparation, spread on the bottom of the boxes containing the paper as it passes through the various stages, effectually dries the contained air, and obviates any reaction occurring until the moment of development, and thus prevents the degradation of the high lights. Finding the calcium tubes sold for this purpose inconveniently small where large numbers and large sizes are required, I some years since designed a special box for the purpose, which I will endeavour to describe.

Well-seasoned pitch pine was planed, dried, and saturated with solid paraffin; it was then made into a dove-tailed box of suitable size, and coated at a high temperature with three successive coats

of shellac varnish. Around the top of the box is a ledge covered with soft, pure (not vulcanised) indiarubber, upon which rests in air-tight contact a heavy sheet of plate glass, accurately fitting the frame thus prepared for it. Over this is inverted another but lighter box of similar construction to the first, to exclude the light, which would otherwise enter through the glass lid. At the bottom of the first or inner box is a flat porcelain tray, on which is spread the dry calcium-saturated asbestos, the paper is kept ready cut to sizes from 12 × 10 downwards, the ordinary japanned tin calcium tubes being retained for the larger sizes of prints and stock of paper. Boxes of similar construction may be, of course, employed for receiving prints from the frames while awaiting development. The frequent unrolling of paper and rolling up of prints prior to placing in the tubes is thus avoided.

At this stage of procedure we find it necessary, when a sufficient number of prints have been made, to assort them into three classes —viz., under-printed, over-printed, and correctly printed. Of course there should be only one class—viz., the correctly printed; but, when there are fifty or a hundred frames to look after, the 20 × 16's and the 15 × 12's naturally claim most attention, on account of the attendant greater loss if the larger sizes are not correctly printed, and thus some of the smaller sizes get sometimes over-done. These may often be saved by dexterous development at a low temperature, while a picture a little too highly printed may be made to yield a vigorous print by prolonged immersion at a higher temperature, and similarly a correctly exposed print may be spoiled by too much or too little of the bath at too high or too low a temperature.

I may not leave unnoticed the cold-bath process, by which very excellent results have been obtained by some manipulators. I have never practised it, being compelled by business considerations to adhere to the process I know to yield results acceptable to my clients.

In the cold process the image is still produced by the reduction of a ferric oxalate to the ferrous state, but the platinic salt is associated with the potassic oxalate in the developer, an arrangement which does not commend itself to my judgment, though doubtless, as already stated, acceptable results are producible.

The "printing-out" platinum paper is obviously one in which the platinic or platinous salt is associated with the reducing agent, and is thus ready for reduction as soon as exposed to the vapour of hot water. I have never tried it. This process is applicable not only to paper, but also to cotton and linen fabrics. The results are beautiful and interesting, but chiefly applicable for decorative purposes, and I much regret that my engagements have prevented me from preparing some for exhibition this evening. The most suitable fabrics are linen, Nainsook muslin, and sateen.

Enlargements in platinotype are made direct by electric light or daylight, but, requiring a prolonged exposure, are liable to loss of sharpness from vibration. In producing them at my Southgate Works, the same plan is followed as in making carbon enlargements —viz., making an enlarged negative first, and then printing and developing in the usual way.

JAMES MARTIN.

RATIO OF GRADATION.

In reply to the able and relevant criticism of Mr. Channon, permit us to say that he has probably overlooked the fact that we have chosen the formula which expresses the connexion between the amount of metallic silver per unit area and the transparency of the film containing that silver, not because it rests upon any clear and rigorous mathematical demonstration, but because it is the expression which best accords with the results of our very carefully made experiments.

The formula $T = e^{-s}$ is not at all our property; it is found in every text-book on physics, and all we claim is to have proved that the silver deposit in photographic plates obeys this law so closely that an optical method of determining the amount of silver may be based upon it.

If Mr. Channon prefers the formula which he ascribes to Mr. Plener, on account of the reasoning on which it is based, rather than the one which we have adopted, and which is so strongly supported by experimental evidence, we have, of course, nothing to say. We submit, however, that the reasoning which leads to our formula (which reasoning is not our property at all) is superior to the reasoning which leads to Mr. Plener's formula as modified by Mr. Channon.

The reasoning upon which this formula we adopted is based does not involve any explanation of *how the light is reduced* by the particles of silver. The reasoning which leads to Plener's formula clearly does involve such an explanation at its very first step. In writing the expression $(1 - a)$ as the transparency of the first layer, the idea is involved that all light which impinges upon the area a occupied by the particles of silver in the first layer is totally absorbed. The next step in the reasoning, to be consistent, requires careful consideration as to the influence of this area a occupied by the silver particles in the second layer upon the area $(1 - a)$ left open in the first layer. To be consistent, the smallest amount of light which could pass would truly be $(1 - 2a)$, but it might be anything between $(1 - a)$ and $(1 - 2a)$, the amount depending wholly upon the relative position of the particles in the two layers in which they are supposed to be equally and evenly distributed, and therefore equidistant. There is no clear reasoning in Mr. Channon's letter which shows that, if the particles of silver in the first layer allow the amount of light $(1 - a)$ to pass, two layers would allow the light $(1 - a)^2$ to pass, or which makes $(1 - a)$ for the first layer into $(1 - a)^n$ for n such layers, if the implied meaning of a be retained.

Nor can we admit that, in reality, the layers are such that all the particles are either wholly above or wholly below a particular imaginary plane. Probably such an arrangement does not occur in nature; nor will nature conform to the first assumption, namely, that the area a of the silver wholly extinguishes the light impinging upon it. But we shall be glad to have Mr. Channon's complete derivations of the formula $(1 - na)^m$, as representing the transparency for m layers, each containing n particles of silver per unit area, and each particle covering the area a.

We here repeat, in another form, Mr. Channon's table illustrating the difference between the two formulæ. In addition to the transparencies, we have given their negative logarithms, which we call the densities; and we show how far the ratio of densities agrees with or differs from the assumed ratio of silver present.

Assumed relative silver.	Transparency.		Density.		Ratio of Densities.	
	H. & D.	Plener.	H. & D.	Plener.	H. & D.	Plener.
1	·9044	·9044	·044	·044	1	1
20	·3660	·3487	·436	·457	10	10·5
10	·1340	·1074	·873	·968	20	22·2
40	·0179	·0061	1·746	2·214	40	50·8
50	·00658	·00098	2·182	3·008	50	69·0

It will be seen that the densities derived by our formula are in the same ratio as the relative amounts of silver assumed, while those derived by Plener's formulæ are not proportional to the relative amounts of silver at all, but grow much faster.

The following are the results of our experiments, made with photographic films of the same thickness, but containing different amounts of silver by reason of having been exposed for different lengths of time to a standard candle. The densities of the negatives were measured in our photometer, and the silver afterwards determined gravimetrically.

Density Measured.	Ratio of Density.	AgCl Weighed.	Ratio of Weights.
·525	1·00	·0163	1·00
·960	1·83	·0299	1·83
1·470	2·80	·0450	2·76
1·970	3·75	·0611	3·74

Density of Silver Formulæ.	Ratio of Densities.	Relative amounts of Silver employed.
3·155	100	100
2·130	67·5	66·6
1·580	50·08	50·0
0·745	23·6	23·8
0·383	10·46	10·0
0·155	4·91	5·0

It will be perceived that this range of densities, with the exception of the first, is almost precisely the range Mr. Channon has chosen for his argument, and it comprises the entire range generally prevailing in good negatives. Within this range it is our formula and not Plener's which is applicable. But our formula is applicable within a much greater range, as is shown by the following results of another experiment, in which equally thick layers of an emulsion containing reduced silver were measured, the relative amounts of silver being adjusted beforehand.

The only other remark which we need make is that Mr. Channon restricts this application of our formula to slow plates. We emphatically state that, though we have investigated hundreds of plates of the most varying rapidity and comprising almost all the well-known commercial brands, we have not yet found one of them which does not yield progressions of densities similar to those published in our paper provided this plate was evenly coated. There are exceptions, as we know but too well; but they are invariably traceable to inequality in the thickness of the film. If Mr. Channon knows of plates

which give results differing materially from those which may be calculated by our formula, we shall be glad to procure them at once, or to receive a sample from him, for the purpose of investigation, upon the results of which we will duly report.

F. Hurter.
V. C. Driffield.

NOTES ON SOME NEW RAPID ORTHOCHROMATIC COLLODIO-BROMIDE EMULSION PROCESSES.*

[Journal of the Photographic Society of India.]

Dr. Jonas gives very full details about the preparation of the colouring solutions. For colouring the solution, various dyes of the eosine series, or cyanin, may be used in combination with silver nitrate and alcoholic ammonia. Each 100 c.c. of the emulsion should contain 1·7 milligramme of silver nitrate and an equivalent amount of dye, as well as a certain quantity of picrate of ammonia and glycerine. The following solutions are prepared:—

I.—Eosine Solution.

Eosine (yellow shade)	4 grammes.
Distilled water	50 c c.
Alcohol (ninety-six per cent.)	450 ,,

If erythrosine is used the proportions are the same.

II.—Silver Solution.

Silver nitrate	3·4 grammes.
Distilled water	50 c.c.

Strong solution of ammonia is added till the solution is clear and alcohol to make up 200 c.c.

III.—Solution of Ammonium Picrate.

Picric acid	2 grammes.
Distilled water	10 c.c.

Ammonia is added to neutralise the acid, and then alcohol to make up 300 c.c.

These solutions are used in the following proportions:—

Solution I. (Eosine)	75 c. c.
,, II.	30 ,,
,, III.	30 ,,
Pure glycerine	20 ,,
Alcohol (96 per cent.)	45 ,,

The solution is allowed to settle for a day or two, filtered, and 20 c.c. are added to 100 c.c. of the plain emulsion.

The formula for use with erythrosine differs slightly from the above—

Solution I. (Erythrosine)	75 c.c.
,, II.	30 ,,
,, III.	30 ,,
Pure glycerine	25 ,,
Alcohol (96 per cent.)	120 ,,
Distilled water	20 ,,

The muddy solution is allowed to stand for a quarter of an hour, and strong ammonia is dropped in till it becomes quite clear; it is then allowed to stand for a day or two, filtered, and is mixed with the emulsion in the same proportion as the above, *i.e.*, 20 c c. to 100 c.c. of the emulsion.

After the addition of the colouring solution, the emulsion is well shaken and filtered through cotton wool, and is then ready for use. The coloured emulsion keeps good only for one or two days and is best used on the day of preparation. It should, therefore, only be mixed in small quantities as required for use. (Some coloured emulsion was found to be absolutely insensitive after a week.)

I have found that the difficulty of keeping the coloured emulsion may be obviated by coating the plate with the plain emulsion, either washed or unwashed, then washing it under the tap and flowing over it the coloured tincture of eosine or erythrosine, diluted to half strength with water. In some cases this may be a more convenient way of working. A solution containing—

Erythrosine	1 gramme.
Silver nitrate	1 ,,
Picric acid	1 ,,
Ammonia (sp. g. ·880)	about 30 c.c.
Spirit of wine	500 ,,
Water	500 ,,

used as a bath has also given very good results.

Dr. Jonas says that emulsions coloured with eosine give soft, harmonious negatives, while the erythrosine gives more density and contrast. I have not yet tried eosine, but erythrosine has given me very bright pictures. In trials with wet collodion, made some years ago, I found than cyanosine gave by far the best results, but it does not seem to do so in this process.

In his paper Dr. Jonas has given an account of the spectroscopic behaviour of his coloured emulsion. It shows the ordinary increase of sensitiveness in the yellow and yellow-green, and, on account of the addition of the picrate of ammonia, is less sensitive to blue and violet. Observations with the sensitometer show that the eosine or erythrosine-stained emulsions containing an excess of silver show about 21° on Warnerke's sensitometer when exposed for one minute at a distance of about ten inches from the standard amyl acetate lamp, and are 350 to 400 times as sensitive as a wet collodion plate under the same conditions.

The exposure is about one-third of what would be given with a wet collodion plate and no yellow screen is necessary in copying paintings, &c. I have found that, practically, the plates coated with washed emulsion coloured by the methods described above, are about as sensitive as Wratten's "Ordinary" plates.

Before coating glass plates with emulsion they must be prepared with a suitable substratum of gelatine, or it may be sufficient to simply pass some of the gelatine solution round the edge of the plate.

Dr. Jonas gives the following formula:—

Gelatine (white)	5 grammes.
Distilled water	500 c.c.

When dissolved add—

Glacial acetic acid	15 c.c.
Alcohol	15 ,,

The plates are well cleaned in the ordinary manner usual for wet plates, and are then flowed twice with the above solution and allowed to dry in a place free from dust.

I find that this solution does not give an even coating, and might be better thinner. It answers, however, very well indeed when applied to the edges of the plate, and can be kept for use as required.

For the coating and development of these colour-sensitive emulsions the light in the dark room must be red, or such as is used for the most sensitive gelatine plates; yellow light will not do.

The plates coated with these coloured emulsions are most sensitive when exposed in a *moist* state. If allowed to dry, they are said to be about ten times less sensitive. I have not tested this, but it seems not impossible to find a method of retaining the sensitiveness of dried plates.

For plates to be coated with the coloured emulsion, all that is necessary is to coat the plate with emulsion, place it in the dark slide, and expose just as it is. In using the bath for colouring, I first coat the plate, then wash under a rose after the coating has *well* set, then flow with, or place in, the diluted colour tincture for a few moments, to thoroughly and uniformly wet it, then drain, put in the dark slide, and expose.

For developing the plates Dr. Jonas recommends a hydroquinone developer which seems to be a slight modification of that recommended by Dr. Albert. The formula is, however, rather complicated:—

Concentrated Hydroquinone Developer.

A.

Distilled water	500 grammes.	
Sodium sulphite	200 ,,	(250 Albert)
Potash carbonate	200 ,,	(250 ,,)

B.

Hydroquinone	25 grammes.
Alcohol (96 per cent.)	100 c.c.

C.

Ammonium bromide	25 grammes.
Distilled water	100 c.c.

The concentrated developer is then mixed in the following proportions:—

A	100 c.c.	
B	5 ,,	
C	7 ,,	(5 Albert)

The proportions of B and C may be varied as necessary, the hydroquinone giving strength, the ammonium bromide clearness, and the carbonate of potash sensitiveness.

The developer for use is made as follows:

Concentrated developer	150 c.c.
Water	1000 ,,

The strength may also be varied according to circumstances.

I have used with good results a hydroquinone developer made up of—

Hydroquinone	1 part.
Sodium sulphite	4 parts.
Lithia carbonate	1 part.
Potassium bromide	5 parts.
Water	100 ,,

Also ferrous oxslate developer as made up by Mr. B. J. Edwards for gelatine plates.

The para-amidophenol developer seems very well suited for these plates and gives clear, vigorous results.

Para-amidophenol hydrochlorate	1 part.
Sodium sulphite	5 parts.
,, carbonate (anhydrous)	4 ,,
Water	200 ,,

First dissolve the para-amidophenol in the water, then the sulphite, and finally the carbonate. In this way there is no precipitate, but if there should be any it may be redissolved by heat.

This developer gives great density and clearness and seems almos

* Concluded from page 168.

inexhaustible. One of the plates I have with me was the seventh developed in a few ounces of it; but, as you will see, it is the strongest of the series, and, indeed, is too strong. After eight plates had been developed the developer was barely discoloured, and would develop many more.

I have also tried pyrogallic acid developer, using the formula for pyro and ammonia recommended by Dr. Eder for a similar process; but, though it gave nice soft pictures full of detail, there was a want of the brilliancy and density shown by the para-amidophenol. It is likely that different developers may be found most suited for different classes of work.

The plates can, if necessary, be intensified, either before or after fixing, with any of the ordinary acid pyro-silver or hydroquinone-silver intensifying solutions, or, if extra density is required, by the bromide of copper or mercurial processes.

For fixing I have used hypo; the image clears at once, and a very much shorter washing is necessary than is the case with gelatine.

Over dense negatives may be reduced with hypo and red prussiate of potash in the same way as gelatine negatives.

As you will see from the specimens I have brought with me, the entire virtue of the process lies in the coloured sensitising solution of eosine or erythrosine-silver and ammonium picrate which was discovered by Dr. Albert. A plate coated with the coloured emulsion and exposed for one minute to a coloured picture gives a fine, dense, brilliant image, well orthochromatised for the yellow, while a plate coated with the same emulsion, but not coloured, and exposed for the same time and developed with the same developer, gives only the ghost of an image. This effect is very remarkable, and its cause is not quite clear. You will also see that with the same exposure and development the collodion plates are quite equal to, if not better than, those taken on Wratten's "Ordinary" gelatine plates, either plain or orthochromatised, under exactly the same conditions. It may be mentioned here that the colouring solution given above when diluted to 1 : 10,000 forms an excellent orthochromatising solution for gelatine plates, though it remains to be seen how they will stand the excess of silver in keeping.

The exact value of the ammonium picrate has yet to be investigated. Dr. Vogel seems to think it unnecessary, but it undoubtedly adds to the orthochromatic effect of the eosine dye.

I am sorry I am not able to show you a more extended series of specimens of work done by the new process, but those I have will, I think, be sufficient to show you its capabilities and possibilities. There is little doubt that the plates may be made more sensitive. The process is certainly a simple one, and, so far as I have yet found, does not require any very special precautions in working. Under the conditions under which we could work it in the office, it would be much cheaper than gelatine and probably even cheaper than wet collodion, certainly so if unwashed emulsion were used. The saving gained in time would be a further economy. The process is not, however, in its present form an out-door process, and is more suitable for copying and studio work. I hope on some future occasion to be able to give fuller working details; my object at present being more to draw your attention to the capabilities and proper value of this interesting discovery of Dr. Albert's, as applied by Dr. Jonas, which appears as yet to have attracted very little notice in England."*

Col. J. Waterhouse, S.C.,
Assistant Surveyor-General of India.

PLATINUM TONING ON MATT-SURFACE PAPER.

[Newcastle-on-Tyne and Northern Counties Photographic Association.]

At the present time there are so many different printing papers in the market, that it is a difficulty with the amateur photographer to decide which process to adopt. The tendency at present is to obtain warmer tones on a rough or matt-surface paper. I hope to demonstrate to you this evening how very simply this is done.

We have all worked with the ordinary albumenised paper, and can, doubtless, produce a good print; and, as the working of plain paper is in every respect similar, I think you will all agree with me that this process is better suited to the amateur's requirements than any other. Very beautiful matt-surface prints can be obtained on any of the various brands of gelatino-chloride papers; but the manipulation of these papers is a little more complicated—the prints require to be passed through an alum bath, and then squeegeed on to ground glass, or (as demonstrated by Mr. Brown at our last meeting) rubbed with powdered pumice stone till the desired surface is obtained. These operations are, of course, not required if you start with the matt-surface paper. Toning takes only a fraction of the time required to tone albumenised paper with any of the usual formulæ for gold baths. Blisters (the *bête noir* of the amateur) are unknown; there is neither albumen nor gelatine present to cause these objectionable comparisons.

The brand of paper I have always worked with is that made by Mr. Valentine Blanchard; he sends his paper out with a supply of toning solution sufficient for the paper. My own toning bath is made up from the formula given in Mr. Lyonel Clark's work on platinum toning, and I may as well mention here that the formulæ I shall have occasion to mention later on are all taken from that same excellent work. I have tried them myself, so can testify to their working satisfactorily.

I will now briefly run through the operations necessary to produce a matt-surface, platinum-toned print, and am sure, if any of you will take the trouble to sensitise your own paper, you will be amply repaid; you will find the home-sensitised paper prints much more quickly than the commercial article, and another great advantage is, you can select a paper with the necessary degree of roughness to suit the subject you are about to print. The paper I have used when sensitising has been Whatman's drawing-paper—this is an excellent paper for the purpose, and can be had in several grades of surface. The rough water-colour paper is specially suited for large prints. It has only one objectionable feature, and that is, it is very porous, and before the end of the washing gets something like saturated blotting-paper; great care is therefore necessary to prevent tearing or otherwise damaging the prints.

Having selected the paper, the first operation is to size and salt it. This is done in one operation, the paper being floated on a solution of chloride of ammonia and arrowroot, as follows:—

Arrowroot	180 grains.
Chloride of ammonia	160 ,,
Water (to one pint)	20 ,,

Or,

Arrowroot	180 grains.
Chloride of ammonia	120 ,,
Recrystallised carbonate of soda	240 ,,
Citric acid	60 ,,
Water (to one pint)	20 ,,

The arrowroot is made into a stiff paste with a little cold water; then about fifteen ounces more water added; then boiled till clear. When clear, it is removed from the fire, and, when sufficiently cooled, the chloride of ammonia, dissolved in the remainder of the water, is added. This solution should be allowed to stand all night; the clear portion is poured off into a suitable dish, and the paper floated on the surface of the liquid. I find Whatman's paper requires about three minutes floating to be properly impregnated with the solution. After removal from the salting bath, the paper should be laid, face upwards, on a level table, to allow the solution to be absorbed, then hung up to dry. I find, if hung up to dry directly it is taken from the bath, that the solution runs down in streaks, and, though not noticed when the paper is dry, unevenness of silvering takes place in consequence. It is as well to salt a good supply of paper when you are about it, as paper in this condition will keep any length of time. The back (or unsalted side) should have a pencil mark put on it for future guidance.

The salted paper is now ready for the silver, or sensitising bath, made up thus: Dissolve—

Citric acid	25 grains.
Water	½ ounce.

And

Nitrate of silver	60 grains.
Water	½ ounce.

These solutions are made separately and mixed. The salted paper is then floated on the solution, care being taken that no air bubbles are between the liquid and the paper. Three minutes will be found long enough for the paper mentioned; it is then removed from the bath and hung up by a wooden clip to dry. This operation must be performed by gaslight, or in the dark room. Paper sensitised in this manner will not keep very long, it is better to sensitise just as much as you require for present use.

Printing is carried on to about the same degree as with albumenised paper till there is a distinct bronzing in the deepest shadows; when sufficiently printed, the prints are washed in several changes of water and toned in following solution:—

Chloroplatinite of potash	4 grains.
Nitric acid	1 or 2 drops.
Water to	2 ounces.

On immersion in this toning bath, the print immediately begins to darken and toning to the black stage is arrived at in about five minutes. If warmer tones are required, it is better to dilute the bath to four ounces with water. The action is then more under control, the toning action stopped as soon as the desired tint is obtained.

Fixing is conducted in the ordinary hypo bath; four ounces of hypo to one pint of water made slightly alkaline by the addition of a few drops of ammonia. I find, however, this alkaline bath has a tendency to produce a warm tone, and if a black tone is desired I use the acid fixing bath recommended for negatives containing one ounce of bisulphite of soda and four ounces of hypo to the pint.

After fixation the prints washed in the usual manner to free them from hypo and dried between blotting-paper.

Having now briefly run through the necessary operations from plain paper to finished print, I think you will all agree with me that this process is about as simple as any. You have nothing new to learn, simply print, tone, and fix with the usual intermediate washings, and you obtain a picture which will be "a thing of beauty and a joy for ever."

T. O. Mawson.

* Since the above was written I notice that Dr. Jonas' paper has been translated in full in *The Amateur Photographer* for July 17, 1891.

THE LEGAL SIDE OF PHOTOGRAPHY.

[Leytonstone Camera Club.]

The lecturer divided his subject under the following heads:—1, Copyright Act; 2, Injunction, with damages, for breach of contract or good faith; and, 3, Caricature of a photograph amounting to libel. Under the first head of the Copyright Act were contained the subdivisions, first, of an assignment from one photographer to another; and, second, of the relation between the sitter and the photographer. The Copyright Act, 25 & 26 Vict., c. lxviii. s. 1, provided that, at the time of assignment of any painting or drawing of a negative of any photograph, the vendor was not merely by reason of his purchase entitled to the copyright, for it was provided, at the close of the section quoted, that the vendee should not be entitled to copyright, unless, at or before the time of sale, an agreement in writing, signed by the vendor or his agent, should have been made to that effect.

The strict interpretation, therefore, of the section led to the result that, if there had been an assignment of the property without simultaneous assignment in writing of the copyright, the assignee would have no title to enter himself at Stationers' Hall as holder of the copyright. But, modified by judicial decision, this is not actually the law. The lecturer pointed out, that both in this and other cases it would be impossible to understand the relation between legislature and judicature without a general view of the mode in which our statutes were framed. A Bill is introduced, drawn by a skilled draughtsman, of which its unity and consistency is dependent on the relations of the details to the leading conception in the draughtsman's mind, and the result of its alteration by a Committee and by the House, without sending it back to the draughtsman to be finally put into shape, is precisely the same as if a committee of artists, each armed with a pencil, were allowed to make such alterations as they thought fit in an able sketch that was brought to them. The result is that, when an Act comes before the Courts, there is in some clause a ludicrous perversion of justice that compels the Court to give some subtle and ingenious twist to its meaning in order to make it consistent with common sense and equity. This fate the Copyright Act has not escaped, for, in Graves's case, 4 Q.B.R., p. 715, one Walker, having been fined under the Copyright Act for piracy of copyright, at the suit of Graves, appealed, on the ground that the painter of the paintings in question had not registered its title, neither had the assignments prior to Graves's been registered, and that Graves therefore had no copyright. The Court, however, decided that it was sufficient that Graves was registered as proprietor; that it was not necessary for him to deduce his title; and that, consequently, there was a valid copyright that had been pirated. This is an obvious evasion of the Act, but an evasion on equitable grounds; but, of course, the judges did not profess to evade it, but gave subtle and ingenious reasons for making the clause mean the reverse of what the unaided human intellect would suppose it to be. In point of fact, the legal eel cleverly wriggled out of the legislative frying-pan, but did not upset it.

The law, therefore, enables any undisputed proprietor of a negative to register as proprietor, subject to his stating on registration the name of the true author. But as to who is the author is again decided by the Courts; one might suppose that the proprietor of a photographic business was the true author, and, in point of fact, primary owner of any photograph taken on his premises, and that his salaried assistants were no more the authors than would a merchant's accountant be, as between him and the world, the author of the merchant's accounts; but, under the case of Nottage and Another against Jackson, the Court decided that the author was not the principal of the photographic business, but that such author was the skilled artist who actually took the negative. Thus it was clear that in law the copyright of an ordinary photograph belongs, in the absence of an assignment, to the actual individual who takes it, even though this individual be the paid servant of another, and uses his employer's utensils.

This was confirmed by Mr. R. Thiele, of the London Stereoscopic Company, who, in the course of a discussion with the lecturer, gave some interesting particulars of the custom of the trade. The lecturer stated generally that it would be better for any one, as far as possible, to stick to the literal meaning of the Act, so far as circumstances would permit, rather than rely on any subtle interpretation given by the Courts, which in some subsequent case might be modified in some other way. Again, in reference to the second point under the Copyright Act, namely the relation between the sitter and photographer, the Court had leaned towards the alternative that the sitter had the property in the negative, because it was executed on his or her behalf. But this was simply a dictum arising incidentally, and there had been no case on the point. It would be simply ridiculous to deny that the photographer was entitled to the plate where, as usual, the sitter had paid for a dozen or two copies, with the arrangement that he was to get further copies at a reduced price; and, if the point were expressly raised, it would probably turn on the question, that what was executed on behalf of the sitter was not the negative, but the copies from the negative, and that the contract would be interpreted by the invariable usage that the photographer retained the negative, and that the understanding between the parties did not include anything else but the copies or positives that were contracted to be paid for. Mr. Thiele, in afterwards commenting on this point, stated that the usage of the trade was to consider the negatives as the property of the photographer, but with the limited right of use subsequently referred to in the lecture.

Referring, now, to the question of the use that may be made by the photographer of copies from the negative in the absence of an express or implied permission, it was shown that in the case of Pollard *versus* the Photographic Company, the photographer was restrained from selling or exhibiting copies for example as a Christmas card exhibited in shop windows, because he was bound to give copies only to the sitter, or by his or her direction, and that any more extensive publication was not only a breach of contract, but a breach of faith.

Turning now to the question of amateur photographers, the lecturer expressed some doubts as to the mode in which the law could possibly deal with them, seeing that, when an amateur photographed his friends, any improper use of the photograph could neither be considered a breach of contract nor a breach of faith incidental to contract. But a hint appeared to assist the matter, both in the case of the limited use allowed to be made by the receiver of the letter, whose property it undoubtedly was, and therefore not a matter of contract, and also in the case of a person who had intruded into a lecture-room, without the lecturer's privity, and was restrained from publishing a shorthand copy of the lecture, though, in this case also, there was no contract between the lecturer and the copyist, and therefore, strictly speaking, no breach of faith. In like manner, if an amateur scattered copies about of his friend's photograph, it is probable that, even in the absence of contract, he might be restrained from making a public use of the copies, which was not justified by the fair understanding between his friend and himself at the time. This, however, is purely speculative, and the recommendation to be given to amateur photographers was that, if they ever took any one else's photograph except for his own use, it would be better to have express permission if a more extended use was contemplated. T. Watson Brown, B.A., LL.B.

PHOTOGRAPHY IN THE COLOURS OF NATURE.

In an article on "Natural Colours on the Lantern Screen" (British Journal Photographic Almanac for 1892), Mr. Albert W. Scott makes the following statement:—

"A brief description of the (Scott) process was published by the writer in The British Journal of Photography in January 1891; and a demonstration with his apparatus was given early in May, before the Manchester Photographic Society," &c. "Soon after, in June, Mr. Ives brought before the notice of the Franklin Institute a similar apparatus, arranged by himself, on the same principle; that is, all three negatives were taken on one sensitive plate, were projected by a special lantern front, in such wise that the three images accurately coincided on the screen. Both these demonstrations appeared to be very successful."

The above appears to me to be about as unfair and misleading a statement as human ingenuity could devise. I believe, however, that the unfairness may be due partly to ignorance of facts. Already I have had occasion to show that Mr. Scott has given his own name to an ether saturator which could not be manufactured in this country without infringing my rights under two patents granted to me for original invention; and now, after bringing out a degenerate imitation of a method of projection upon which I have been working for many years, achieving notable success years before Mr. Scott attempted anything in this direction, he would have it appear that I am the imitator instead of the one who is imitated. The fact is, that I have copied absolutely nothing from Mr. Scott, and would gain nothing by doing so; while, on the other hand, Mr. Scott has already copied many things from me, without giving credit for anything, and will have to copy from me in every essential particular before he can possibly produce results worthy of comparison even with those which I showed in February 1888.

With reference to Mr. Scott's claim to have originated the triple camera and lantern slides (both worthless so long as the negatives are made from separate points of view, as in Mr. Scott's camera), I have to call attention to the following facts. The first exposure I ever made on a landscape for purposes of colour projection was with a single plate, sensitive to all colours, behind three lenses, with selective colour screens, and diaphragms adjusted to make the three pictures develop together. My reason for doing this is indicated by statements made in my first communication to the Franklin Institute upon this subject, when I said, in one place, that I used "photographic plates sufficiently sensitive to all parts of the visible spectrum. Means for filtering out, in a strictly accurate manner, such coloured rays, and in such quantity or proportion as may be required." And, in another place, "I find it necessary to prepare the three sensitive plates at the same time, with the same emulsion, and to develop them in the same developing solution for the same length of time." But I added also another requirement, as follows:—"A camera that will produce three negatives simultaneously, of exactly the same size, and from the same (or very nearly the same) point of view." This latter requirement

explains why, in 1888, I cut the single plate into three pieces after preparation, in order to secure the same chemical effects without destroying the coincidence of perspective required to secure register in the finished results. Mr. Scott has merely gone back to a plan which was old, and partly abandoned for its imperfections in 1888: and the successful return to my original plan has not been made possible by any invention of Mr. Scott's, but by my own invention of a camera that makes three negatives on one plate from one point of view.

The use of a single lantern slide from the three negatives is also my own idea. The slide, shown successfully in February 1888, was a single wood-mounted slide, and was projected with a single lantern, having three optical systems as close together as possible. Dozens of the members of the Franklin Institute examined with interest both the slide and the construction of the lantern. One reason why such details were not published is that such details are not patentable in this country, as in England; and another, that they are very trivial matters in comparison with the invention and demonstration of a scientific solution of the problem of colour-reproduction by photography.

The triple lantern-front devised by me is entirely different from Mr. Scott's, and, unlike his, is interchangeable with the ordinary projection lens, without change of light or condensers. Already, although it possesses important advantages over Mr. Scott's device, I have given up its use with the limelight, because my device of 1888 gives so much better illumination.

Mr. Scott's statement, that his demonstration, like my own, was successful, is disproved by his admission that landscape reproductions were unsuccessful. The processes of Du Hauron, Albert, and others, made striking, though not true, reproductions of highly coloured objects, but necessarily failed to reproduce the delicate colours of natural landscapes. Mr. Scott's process, based on a very old and long-exploded theory of colour, also necessarily fails on such subjects.

In conclusion, although every special device employed by me in carrying out my process of composite heliochromy is an original invention of my own, and superior to any imitations or substitutes so far known, these inventions do not represent one-fiftieth of my labours in composite heliochromy, and are of comparatively small importance. It is clear that substitutes may be found for mechanical and optical devices, but it is very doubtful if good results can ever be produced with any of them unless they be used to carry out a principle which is distinctly my own, and by which success has for the first time been achieved.

F. E. Ives.

[The foregoing, which was posted in Philadelphia in January last, only reached us during the preceding week, having just been recovered from the wreck of the *Eider*.—Ed.]

ELEMENTARY NOTES ON PHOTOGRAPHIC LENSES.*

Modifying Lenses.

Full advantage is rarely taken of the power of modifying or temporarily altering lenses for special requirements, and giving them qualities that in their original form they did not possess, although to any one whose stock of lenses is limited this power may at times be of immense value, as they may be made to work satisfactorily where they would otherwise have failed entirely.

The most simple modification is that of using either of the single lenses of a rapid or wide-angle rectilinear alone, giving a lens of about double the focus of the compound. In many rapid rectilinears the front lens is of longer focus than the back, so that there is a choice of two. If the front lens is used alone, it should be screwed into the back of the mount. With these single lenses it must be remembered that, by the alteration in proportion of aperture to focus, the exposure will require to be about four times that for the same stop when using the compound lens; and also, from the fact of a stop being necessary with any single lens, that, although a rapid rectilinear may give brilliant definition with full aperture, yet the singles of which it is composed will not work satisfactorily without stopping down to about half their diameter, or using the stop marked *f*-16, which will then be about *f*-32. These single lenses being about double the focus of the compound will give an image of any object about twice the size, or they will cover a much larger plate well, and include on that a similar view to that given by the original lens on the smaller plate. The stop being much nearer the lens than it would be if the single had been specially constructed and mounted to work as such, the distortion is very slight, and, when used on the same size plate as the original lens, it is practically rectilinear, and may be used for any work.

A rapid rectilinear may be converted into a wide-angle of the same focus by having a short mount made to carry the combinations closer together, the gain in covering power depending on the extent to which they are closed in. This does not alter the focus of the lens to any material extent, so that there is no difference in the size of the image that it will give on the plate that it would cover in its original form. The gain is, that it may be made to cover a considerably larger plate, and one that includes a wide-angle. As an example, a half-plate rapid rectilinear may have its covering power increased to enable it to be used for 10 × 8, or even 12 × 10 plates. There is no gain without a corresponding disadvantage, and this is no exception to the general rule. The principal objection is, that the field is rendered very round, so that, in taking advantage of the increased covering power, small stops have to be used in order to bring the edges and centre of the picture sufficiently in focus together. For that reason the new mount should not be shorter than is necessary to cover the plate required. The closer the lenses are brought together, the greater will be the covering power, but the more will flatness of field be lost. For those who rarely have occasion to use a wide-angle lens, the necessity for using smaller stops is not such a great objection, as in other respects it works well.

The front lens of one rapid or wide-angle rectilinear may be used with the back lens of another to produce a new combination having a focus intermediate between the two from which it has been formed; so that, if the front lens of a ten-inch rapid rectilinear is used with the back lens of a six-inch, the new combination formed will have a focus of about eight inches, or probably a little less. This combining two lenses to form an intermediate size can be effected with scarcely any loss of quality, and in some instances critical examination will fail to detect any material difference in flatness of field, covering power, or evenness of lighting.

To obtain the best results, three conditions are essential. First, the longer focus of the two lenses should always be in front; second, the distance between either lens and the stop should be the same as in its original mount; third, similar lenses of the same maker should be used. Dissimilar lenses may be combined as two of different construction, or even a rapid and a wide-angle rectilinear; but in that case the result will not be so good, and smaller stops will have to be used in order to make it work well.

Where the focus of each single combination is known, the focus of the compound lens that they would form can be easily calculated, and so determine whether it would differ sufficiently from others already available. The formula is, let A and B represent the focal lengths of the two lenses, and C their distance apart in the mount, then the focus = $\frac{A + B}{A + B - C}$. With a single lens the curvilinear distortion varies with the distance between the lens and stop. By bringing these closer together the distortion may be so minimised, that it becomes inappreciable, and the lens may be used for architectural work. Its effective diameter is reduced the nearer it is to the stop, so that it necessitates a much smaller aperture in order to obtain crisp definition and flatness of field; consequently, the extent to which the mount is shortened should depend on the distortion given by the lens under its normal conditions of working.

Selection of Lenses.

In giving these modifications of lenses, it is not intended that they should take the place of those specially made for certain work; but there are very few amateurs who can provide themselves with a large number of lenses, and those who have one or two only may, by some of these methods of obtaining other forms or combinations, produce satisfactory negatives of subjects which otherwise it would be useless to attempt. The selection of a lens by an amateur should not be a difficult matter, if the class of subject for which it is required, and the qualities and disadvantages of the various forms are carefully considered. For those whose principal aim is pictorial landscape, with occasional figures or slowly moving objects, a single lens working at *f*-16, or, for special objects, *f*-11, would be the most satisfactory instrument possible. It is sufficiently rapid for shipping and sea pieces generally under favourable conditions, as these subjects are almost invariably well lighted. If great variety of work is to be done with only one lens, the most useful would be the rapid rectilinear, as this answers well for such a wide range of subjects and conditions where other lenses, specially good in their own sphere, fail.

A very good equipment for amateur work generally, where two lenses can be provided, would be, for half-plates, a single about nine inches focus and a wide-angle rectilinear about six inches, for most architectural subjects, interior and exterior, have to be taken in confined positions, where the use of a longer focus lens is less satisfactory or impracticable. The back combination of this would be about twelve inches focus, and available for those subjects in which the nine-inch single would include

* Concluded from page 167.

too much. This is practically three lenses, a sufficient outfit for all work excepting that of such a character as to require special provision under any circumstances.

For racing, animals in rapid movement, or similar subjects under a variety of conditions, a lens of great rapidity, such as an euryscope, will be almost a necessity, though an objection to this is the accurate focussing required, owing to the very small depth of focus that its large aperture allows. For the majority of instantaneous studies a rapid rectilinear will fulfil all requirements.

Any technical question connected with photography must, in order to be of practical utility, have a direct bearing on its artistic aspect, by rendering the production of a desired result more certain and definite. While technical perfection alone would be insufficient to produce a picture, yet equally artistic perception and training are of little value to their possessor unless he has also the manipulative skill necessary to give full expression to his artistic creations. HENRY W. BENNETT.

PLATINUM TONING AS APPLIED TO GELATINO-CHLORIDE PRINTING-OUT PAPER.

[Newcastle-on-Tyne and Northern Counties Photographic Association.]

FASHION, which regulates the cut of our garments, has, as might be expected, some considerable influence in matters photographic. During the past two years there has been a steady movement in the direction of warmth of tone. In the higher regions of photographic art there was a time when "Big and Black" held supreme sway, and anything approaching tones which most of us now admire was a thing held accursed. Now men's minds are everywhere asking, How shall we arrive at the warmest tones? and skilful concoctors of formulæ are holding high revel in their search for the mystic process which shall forthwith make all things sepia. The numerous methods of toning (or staining) bromide papers recently published afford evidence of how strong is the revolt against blacks. We have, indeed, need to be careful lest, by over-doing it, we induce a revulsion of feeling. Above all, let us not outrage the eternal fitness of things by such proceedings as printing winter landscapes a bright red, and so forth.

Amongst all the methods of getting rich warm tones, I know of none equal to that which it is my privilege to bring before you to-night—viz., the use of a gelatino-citro-chloride of silver paper and chloro-platinite of potassium as the toning agent, as by its means we can get tones of the most exceeding richness and warmth with ease and certainty.

GELATINO-CHLORIDE DESCRIBED.

After lying stagnant for many years, the gelatino-chloride process has at last become very popular. In its original form it was a collodio-chloride emulsion, invented by Mr. G. Wharton Simpson in 1865. It never made much headway—why, it is difficult to say. To my mind, a collodion image is in many points superior to a gelatine one. Amongst its principal exponents was a north-country photographer—Mr. George Bruce, of Duns. In 1882 Captain Abney proposed a gelatine emulsion, and his formula became the foundation on which every one has subsequently built, until the analogous collodion paper was almost forgotten. On the Continent, however, there has for the last year or so been in use a collodio-chloride paper, and recently a similar product, under the name of Celloidin paper, has been introduced into the London market by Messrs. H. Kuntzen & Co., samples of which I show you to-night. The late Herr Obernetter was first in the field, in 1885, with his now celebrated emulsion paper, followed by Liesegang, and after the lapse of five or six years we now have the choice of at least two brands "made in England."

My intention to-night is not to read a scientific paper, or to indulge in any theoretical or chemical speculations, but rather to go upon solid ground, over which I have myself trodden, steering clear of everything which has not been thoroughly substantiated in my own experience, and will treat (1) of printing, (2) of the toning bath, (3) of the process of toning, and (4) of finishing.

It may be mentioned here that my experience almost solely relates to Obernetter paper, but I have handled nearly every brand in the market, and shall have something to say of each.

Printing is conducted in the ordinary way, any negative that is not either hopelessly thin or dense being suitable. Contrary to the text-books and advice so plentcously given, it is not necessary to over-print any more than on albumen paper—in fact, to do so is in most cases distinctly harmful.

After toning with platinum, no paper I have yet tried reduces to any great extent in a properly made fixing bath, and if we desire a matt surface, and so squeegee on ground glass, that operation considerably adds to the depth of the image; so, if we over-print, "leatheriness in the shadows" will result. It is necessary to remember, however, that the depth of printing must have some definite relation to the tone we desire to obtain. This will be discussed when we come to the toning stage.

The toning bath which I have found to be the best is a simple one:—

Potassium chloro-platinite	1 grain.
Citric acid	10 grains.
Distilled water	4 ounces.

A platinum bath will only work when acid, and the use of citric acid, instead of nitric, as usually recommended, is a great improvement, due to Professor Burton, who found that the latter acid has a staining influence upon gelatine.

Other baths have been recommended, which are not so good as the above, and possess the serious disadvantage that they will not keep, whereas this one will keep indefinitely provided the prints be properly washed before toning, so as not to contaminate the bath by silver salts. I have here a bottle containing a bath made up over two years ago, which has been in constant use ever since, strengthened when necessary by adding more platinum, which I keep in a dropping-bottle mixed in the proportion of one part platinum to twenty parts water. When of proper strength, the bath is of a dark straw colour, and as the toning agent is used up the solution becomes paler, so that by a little observation it is easily seen when the bath wants strengthening.

THE MANIPULATIONS OF THE PROCESS.

Coming to the actual manipulations, the first item is the preliminary washing, which must be *thorough*. The first wash must be rapidly performed, so as not to keep the prints soaked in the dissolved-out silver, else yellowing of the high lights will result. After four changes of water, it is necessary to dissolve out all the remaining free silver by a salt bath. After a minute or two in this, and another rinse in water, the prints are ready to tone. At this stage they are but little changed, and the process of toning, unless much prolonged, produces no effect that is visible to the eye. We only discover what tone we have got when the prints are in the hypo bath; but the action is so regular that success is certain. It is instructive, however, to see what colour of image we are working upon by fixing a print without any toning, and I will presently show you a few examples. It will be found that the image suffers a very considerable reduction, and partakes of a yellowish-red hue. By simply fixing without toning, warm red tones can be got if we print deep enough to compensate for the reduction that takes place, and there is no reason to suppose that such images should fade any more than does a bromide print. Indeed, the chances are in favour of the former, as it has not been in contact with any salts of iron, or acid clearing bath. I have spoken of the necessity of keeping up a definite relation between the depth of printing and the ultimate tone desired. Simply fixing a print much reduces its depth, but the more platinum we associate with the silver image the less does it reduce. This applies to all papers, but in a greater degree to the Ilford "Printing-out-paper." Toning then proceeds on certain definite lines, the stages being red, reddish-brown, sepia, brown, dark brown, and purplish-brown. For the first stage, printing ought to be continued till the deepest shadows are slightly bronzed, and the toning will take, say, five minutes. With such an over-printed image, longer toning seems to intensify the print, and to block up the shadows. For any other tone than red, it is not advisable to print till the bronzing stage is reached, but to stop when the whites are slightly tinted, and toning will be accomplished in from five to fifteen minutes. The warmth of tone, which is the characteristic of this process, it is evident has for its foundation the yellowish-red of the silver image, and, as we associate it with platinum in a greater or lesser degree, the tone varies from a warm red to the other shades I have named. There have been various attempts to completely substitute platinum for the less stable silver, but with no success. It was first supposed that the toning process was a depositing of metallic platinum upon the image; then it became the belief that a partial substitution took place: but Lyonel Clarke, in his book, assumes, with considerable show of reason, that an alloy of silver and the nobler metal takes place. Be that as it may, it is a process which, for certainty and beauty of results, merits every one giving it a fair trial.

After toning, the prints may be immersed in a weak solution of common soda, to neutralise any acidity present and stop toning, or may be placed direct in the fixing bath, made distinctly alkaline with ammonia, and not stronger than one part hypo to eight parts of water. For the sake of giving the prints a fair chance in the battle of life, it is advisable to have the hypo bath fresh, and to fix for not less than half an hour. After thoroughly washing in copious changes

of water, the prints are given a five-minutes' soaking in a bath of chrome alum of about twelve grains to the ounce. To avoid acidity, neutralise this with ammonia, and filter out the dense precipitate which is formed. This is of the greatest advantage, as it hardens the gelatine and renders it almost impervious to damp. So great is its hardening effect that a print so treated and dried cannot again be softened, and resists water almost boiling.

The next stage is the squeegeeing, which is best done upon finely ground glass. Bear in mind, however, that this must take place as soon as they are washed free from the chrome alum, as, if they are allowed to dry, they cannot be so treated. The adoption of the alum bath makes the sticking of prints to the glass almost an impossibility, and this is no small advantage. Much rubbish has been written about cleaning the glass plates previous to putting down the prints—by myself amongst the number. If really dirty, monkey soap will remove it all. Flowing hot water over the plate, and rubbing with the palm of the hand, will do the rest. It can then be placed under the tap and cold water run over it, then place the wet print in position, with blotting-paper on the top, then a piece of waterproof sheeting, and squeegee vigorously. It is necessary to remember that any attempt to remove the prints before they are dry is to court failure. A matt surface may be got much more easily by the use of finely ground pumice-stone powder, rubbing it on the dry print by hand. Mounting presents no difficulty if the prints be properly hardened in the alum bath.

Characteristics of Various Papers.

It only now remains for me to briefly indicate some of the characteristics of the various brands of paper.

Obernetter's ordinary brand gives very fine results (his other makes I have not tried). Over-printing in the ordinary sense is not advisable, although there is a small amount of reduction. The paper is thinner than some others, and therefore must not be roughly handled.

Celerotype is a thick paper, and tones easily—printing normal.

Jacoby's requires deeper printing, and has a good range of tones, the warmer shades possessing a distinctive quality not seen in any other paper.

Luminotype, Talbot's "Beta," and Liesegang's aristotype behave well, and there is no great difference in result between any of them; but they have one defect in common, or, rather, the samples I have had through my hands possess that defect, viz., they are stained either pink or mauve.

Kuntzen's celloidin is a thoroughly good collodion paper, unfortunately also stained mauve, normal printing, and tones easily, yielding similar results to gelatine; but, on account of the hardness of a collodion image, it cannot be squeegeed.

Ilford "printing-out paper" possesses characteristics of its own. It does not require such deep printing as any of the others, and will not pass to the bronzing stage. Deep printing is indicated by blocking up of the shadows, but this point must not be reached unless short toning and reddish tones be desired. In my hands it has yielded a greater range of colour than any other brand (from yellow to almost purple). For anything approaching full toning great care must be taken not to over-print.

James Brown.

HOLBORN CAMERA CLUB EXHIBITION.

The third Annual Exhibition of the members of the Holborn Camera Club was held at Anderton's Hotel, Fleet-street, on Saturday last, nearly two hundred visitors being present. Mr. E. Clifton, Mr. F. A. Bridge, and Mr. Horsley Hinton were the judges.

In Class 1, Mr. A. J. Golding obtained the first prize for the display of the most numerous and meritorious pictures. This member sent in eleven frames of various subjects, figure studies being predominant. One of the pictures, *Going out to Sea*, an enlargement on Fry's rough paper, was awarded a silver medal. This is a photograph of a tug towing a large sailing vessel out to sea, and was full of life. Mr. Fred Brocas was awarded second prize. Mr. Brocas sent in eighteen frames, the best being some examples of Devonshire scenery.

In Class 2, Mr. H. West was awarded a prize for the best display of pictures by new members. One of his pictures, *At Rest*, obtained honourable mention. This was a bromide print, after the style of Mr. Cembrano. Two enlargements of rushes were also exhibited by this member. Mr. A. Bell obtained a prize for the best exhibit of members who had started photography during the last year. This member exhibited a frame of six country scenes.

In Class 4, Mr. E. H. Bayston was awarded first prize for a set of portrait studies, and Mr. Sharpe obtained second prize. Mr. Golding sent in an enlargement of the head of *An Old Salt*. Mr. H. Beckford was awarded first prize for the best display of six half-plates. These consisted of two interiors and some shipping scenes. Mr. A. Hodges obtained second prize for some good country scenes. Mr. E. Elsworth was awarded first prize for the best set of six quarters, while Mr. H. Thompson obtained second prize. Mr. West sent in an excellent set of six tree studies in this class. Mr. Chang was awarded first prize in the lantern-slide competition, and Mr. T. O. Phillips obtained second prize. Messrs. Fry and Eastman sent some pictures for exhibition, and the *Graphic* exhibited a large number of pictures. The *Daily Graphic* sent in a series of frames showing by the process by which the pictures were made, the first being the drawing as sent in by the artist, the next the negative taken from it, then the block in its different stages, and, finally, the print as it appeared in the paper.

During the evening two lantern entertainments were given. Mr. Sinclair gave *A Scamper through Normandy*, and Mr. Whiting some fine slides of Canterbury and Shakespeare's country.

We congratulate the Club upon the high level of excellence shown by the various exhibits, as well as upon the success of last Saturday's display and entertainment, which the pressure on our space obliges us to treat with all possible brevity.

EXHIBITION OF ENGLISH PHOTOGRAPHS IN BRUSSELS.

During the Congress held in Brussels last year, a small collection of English photographs attracted such favourable attention that it was immediately proposed to organize a representative exhibition of English work. A Committee of the Association Belge, consisting of Messrs. Maes, Puttemans, Alexandre, and Colard, was charged to organize the exhibition, and thereupon they invited a number of well-known English photographers to contribute to it. The display will accordingly open on the 25th of this month, at the Cercle Artistique et Littéraire of Brussels.

The exhibitors include Captain Abney, Messrs. Burchett, Byrne, Gambier Bolton, W. Crooke, L. Clarke, G. Davison, Distan, Dresser, Horsley Hinton, R. Keene, Maskell, H. P. Robinson, Vanderweyde, West, Winter, and others. Some of Mrs. Cameron's pictures will also be on view.

The promoters of the Exhibition have paid English photographers the high compliment of saying that the artistic qualities of their pictures have induced them to take this step, in order that Belgian photographers may profit by a study of them. Succeeding annual exhibitions will be devoted to the representative work of other countries, but "the English exhibition naturally comes first." Messrs. G. Davison and Lyonel Clarke have rendered the Association Belge valuable assistance in the work of organization.

Our Editorial Table.

Manuel Pratique de Phototypie.

Par J. Voirin. Paris: Ch. Mendel, 118, Rue d'Assas.

The author of this small manual handles his subject in a thoroughly practical manner, and provides a complete and lucid guide to phototypic printing. Two specimens of the process and a number of illustrations of apparatus are given in the text.

Obernetter-Perutz Negative Films and Sheaths.

Mr. J. R. Gotz, who is agent for these films, has sent specimens of the same, which we have tried, and find to give results which are

most excellent. Possessing a high degree of sensitiveness, they develop clean and with all desirable gradation.

Mr. Gotz's film sheaths are admirable pieces of workmanship. He has constructed special apparatus for making them, a feature in the apparatus being that he can make them of every size and with perfect flatness.

Ilford Isochromatic Plates.

The Britannia Works Company.

These plates are issued in two brands, these being respectively of instantaneous and medium rapidity. If we judge by the samples which we have received, these plates "have come to stay." No one knows the value, under exceptional circumstances, of colour-sensitive plates better than those who have tried, say, to copy a painting without them. A very fine optically worked glass screen accompanies these samples. This is set in a frame suitable for placing behind the lens, and greatly facilitates the ensuring of colour values. But, as we have formerly said, it is not wise to employ this in every case, as there are many subjects in which an exaggeration of the colour values of subjects might be produced. We are glad to see good isochromatic plates placed on the market under such favourable commercial conditions as those initiated by the Britannia Works Company, and can hazard a prophecy as to their popularity.

From Mr. Otto Schölzig we have received specimens of Dr. Jacoby's Collodion Emulsion Paper. This gives fine detail, and is used and treated in exactly the same way as ordinary albumenised paper. Formulæ for toning and fixing bath, accompanied the specimens. The paper can be had in three tints—white, pink, and mauve.

The Optics of Photography and Photographic Lenses.

By J. Traill Taylor. London: Whittaker & Co.

This work, which contains 244 pages and sixty-eight illustrations, and is dedicated to Captain Abney, is stated, in the preface, to be for the users, and not the makers, of photographic lenses. The subjects treated of embrace, among numerous others, Photographic Definition, Real and Ideal; Aberrations, Spherical and Chromatic; Deep Meniscus Lenses; Single Achromatic Lenses; Combination Lenses of the various types now in use; Distortion, its Nature and Cure; Foci, Testing Lenses, Lenses of Jena Glass, Lens Grinding, Lantern Optics, Photo-Telescopic Lenses. Each class of lens described has been associated with the name of its inventor, and the author expresses a hope that the work will prove useful to professionals and amateurs alike. It is obvious that no opinion of the merits of the book can be expressed here, but this does not prevent us from congratulating the publishers on its excellent printing and get-up.

Messrs. Hunter's Catalogue gives full particulars of the firm's specialities—print trimmers, plate rockers, washers, &c. There are some useful hints on mounting and burnishing in the book.

Fallowfield's Photographic Remembrancer is, as heretofore, a testimonial to the enterprise and activity of this firm. It is up to date.

PATENTS COMPLETED.

Improvements in or Pertaining to Photographic Camera.

No. 6533. Richard Whitehorne Savage, 22, Bagby-road, Leeds, Yorkshire, and The Sun Camera Company, Limited, 22, Bagby-road, Leeds, Yorkshire.—*February 20*, 1892.

The object of our invention is to improve the construction and fitment of photographic cameras in various details, to render the same more efficient and generally convenient.

We erect two standards of a semi-circular or curved section wherein the front of the camera can slide, and which front is constructed with a central circular opening into the front whereof the lens tube can be screwed, while on the internal edge thereof is a flange which may extend as far therearound as desired. A frame is secured to the front end of the bellows which has a corresponding circular opening, and certain parts are removed from the edge of this opening corresponding with the aforesaid flange, which parts being brought together, the frame is pressed home and partly turned to cause the edge of the aperture to pass behind the flange, and thus secure the two parts together after the manner of an intercepted screw, proper stops being fitted and the two parts being light-tight. To this sliding front is fitted a horizontal pinion shaft actuated by a screw-head which gears into racks on the standards to raise or lower the front. Stays can be fitted to the standards, and through the upper parts thereof clamping screws are fitted to the standards, the heads whereof pass through slotted plates on the sides of the sliding front to retain the same at the desired elevation. The standards can be erected on a movable platform fitted in the base, on the edge whereof is a rack into which a stationary pinion engages to move this platform transversely, and the platform can be made in two parts, one part being centrally pivoted on the other part, and thus, while the lower part only moves transversely as aforesaid, the upper part that carries the standards not only moves transversely therewith, but can also turn on its pivot and be clamped in any position by any usual devices.

At the rear end of the base of the camera is mounted a platform, which may be capable of sliding therealong, and through this platform rises the head of a screw bolt, preferably on both sides of the base, fitted with such nuts and other appliances as to be capable of being clamped on and to the web or webs of or to the base. The upper surface of the platform is concave transversely to the base to form a seat for the complementary convex edge of the back, which convex edge is formed on the bottom and on one of the sides thereof to allow the back to be mounted on the platform in two positions, and plates are secured on these edges wherein are the usual slots formed across the same, into which slots the heads of the screw bolts can pass and travel behind the same. By this arrangement the platform can be placed in the desired position, the back can be engaged thereon, and be erected or inclined or laid flat as the slots may allow, and then the appliances on the screw bolts will clamp all these parts together. The platform may also be fixed on the base by one, preferably the front edge, in which case the rear edge is capable of being raised or lowered and there clamped, and then the back will not need to be inclined, and the convex edges are not required, but the back on its two sides as aforesaid can be slid into a groove in the platform.

On this back is the usual focussing screen contained in a hinged frame, and this screen is provided with and can be covered by folding doors, preferably fitted so that when the doors are opened the screen is moved towards the lens and *vice versâ*, and round and between these doors are fitted flexible webs which, when the doors are opened, entirely enclose the screen, except where an aperture is left, through which the focussing can be performed without the usual cloth, and inside the focussing screen a recess may be made in the frame, wherein a negative can be placed for enlargement, or reduction, or otherwise.

The ordinary dark slides may be used in this back or a detachable magazine, for a continuous film can be constructed and applied thereto as follows: A closed cylinder is made to contain a roll of sensitive film, and along this cylinder is secured a semi-cylinder, which can tightly fit on the opened top of the back, inside of which semi-cylinder is a closed cylinder, and a narrow passage is made through this cylinder into the aforesaid cylinder, wherethrough the end of the film can pass to a roll in the latter cylinder, all parts, of course, being light-tight. To the axis of this roll is secured a handle, which may surround the outer side of the back, and when this magazine is placed in position this handle can draw the lower cylinder downwards to the bottom of the back, exposing so much of the film in readiness for the exposure to light, after which the handle can be lifted, and a spring inside this cylinder, so lifted, rolls the exposed film up therein, suitable pawls or stops being fitted to both cylinders to govern the rolls, and then, by again drawing down the lower cylinder, a fresh surface of the film is exposed, and so on.

The base of this camera may be formed as usual, and, to extend the same, a transverse rod, with right and left-handed screw threads, may be mounted on the stationary part, on which threads are winged sleeves, whereto are jointed, preferably on both sides, a series of reticulated bars duly jointed together, the end pairs of bars being jointed to the sliding parts of the base; or these reticulated bars may be fitted on one side only; or when there are two or more sliding parts to be extended on one side, racks can be fitted on all the parts, and the pinions on the transverse rod would first extends the smallest part, and then the next, and so on, and when this base is long the back of a smaller camera can be connected with the front of the bellows of a larger camera by clips or screws, the intermediate back being supported from the base by travelling standards.

This camera can be enclosed in a bag or box, in the bottom and lower part whereof are such apertures as may be required for working the same or connecting it to its stand by its base, to which this bag or box can be attached. The bag or box is divided transversely into two parts which can be opened to expose the camera and closed and fastened to cover the same, and are so fitted as to hold also the dark slides, roll holder, spare lenses, shutters, and other appliances.

A long board has a longitudinal slot, wherein can travel the screw bolt by which this board can be connected to a tripod or stand, and two or more platforms can travel along this board, being fitted with racks and pinions, clamping screws, and other appliances. On one platform a smaller camera can be secured, and on the other a larger camera, the front whereof can be attached to the hood of the lens of the smaller camera by metal strips or otherwise, whereby an enlargement or a reduction may be produced, and this long board will also serve for exhibiting photographs by placing a lantern behind the camera on the one platform, which can be supported by any stand, if desired, while the other platform carries the exhibiting surface.

The camera can be contained in a rectangular rigid casing, which is divided transversely into two parts, the front part containing the lens shutter and other parts, with a finder if desired, and the rear part sliding inside the front part. On the sides of the front part are pivoted two levers, the

upper arms whereof carry or are connected with a magazine of sheathed sensitive plates, while the lower arms thereof are connected with the sliding back. Springs and other appliances are fitted in the magazine to force the plates forwards, and when a plate comes to the front it drops a little way down below the magazine, and engages on each side at its lower part studs on the sliding part of the casing. The exposure is given while the plate is in this position, and then the sliding back is drawn out, forcing this exposed plate down on its face as its lower edge is being drawn back by this sliding back, and the magazine is being moved forwards by the levers, and by such action compressing springs under its sides until, when the back is drawn out as far as allowed, this plate is clear of the magazine, and is by the springs caused to regain its vertical position, when the back can be pushed in again, thus causing the magazine also to regain its normal position with a fresh plate in the front and the exposed plate in the rear, and so on. A suitable door can be made preferably in the sliding back, wherethrough the exposed plates can be removed and fresh ones inserted, and any suitable indicating appliances may show what number of plates have been exposed. The pulling out or the pushing in of the sliding back can also obviously be utilised in setting the shutter by the appropriate means, as also for focussing by a distance scale of the sliding back and otherwise.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 16.—Mr. A. Haddon in the chair.

Messrs. H. Irwin Ward, W. Hiles, J. Sharp, and F. H. Merry were elected members of the Association.

Mr. W. E. DEBENHAM gave a demonstration of the Wet-Collodion process, remarking that it still had its uses in the preparation of blocks for line work. For copying, there were several houses who would not like to be without it. Another of its uses was in making enamels by the substitution process, while, for producing lantern slides by reduction, it had always held its own. For intensifying negatives, such firms as the Autotype Company and the Woodbury-type Company probably employed it. Having pointed out the difference between wet and dry-plate development, Mr. Debenham went on to treat of the nitrate bath, which he himself had always prepared according to a formula that he gave in the BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, 1872. The preparation and salting of the collodion, the cleaning of the plates, the coating and sensitising, exposure and development, were in turn explained, some successful transparencies being produced. Mr. Debenham gave the following formulæ for the collodion, plain potassium iodiser, and bromo iodiser:—

PLAIN COLLODION.

Pyroxyline	100 grains.
Ether (from methylated spirit)	5 ounces.
Alcohol (not methylated)	10 ,,

PLAIN POTASSIUM IODISER.

Potassium iodide	160 grains.
Alcohol (not methylated)	5 ounces.

BROMO IODISER.

Cadmium iodide	50 grains.
Ammonium iodide	50 ,,
Ammonium bromide	10 ,,
Iodine	1 grain.

At the conclusion of the demonstration, the CHAIRMAN complimented Mr. Debenham upon its excellence and success, remarking that, if there were any present who knew nothing of the process, they must surely have gained a great deal of information from listening to, and watching, Mr. Debenham, who had given all necessary details.

Mr. A. C. HENDERSON having made several observations on wet-collodion processes and arising out of Mr. Debenham's demonstrations, it was agreed to adjourn the discussion.

Before the meeting terminated, Mr. A. L. Adams exhibited a binocular pantoscope for viewing transparencies, with a chromatrope attachment imparting various effects to the pictures.

Camera Club.—March 16.—Mr. A. HORSLEY HINTON read a paper, entitled, *Pictorial Photography of Thought*. Mr. F. Machell presided. Previous to the paper, Mr. DALLMEYER explained and exhibited a great improvement in the photographic lens which consisted of a different combination to be used in conjunction with portrait lenses. Some admirable results were exhibited, and much interest in the practical application of the instrument was displayed. Mr. HINTON, in his paper, maintained that, notwithstanding its limitations, photography was capable of expressing individual and personal ideas and feelings. For such facts he himself sought in pictorial work, he preferred to use focussing and printing methods that favoured breadth, and a general, rather than a particularising, effect. On March 31, Messrs. F. P. Cembrano and H. M. Hastings will exhibit a series of slides taken during the last convention.

Holborn Camera Club.—March 11, Mr. D. R. Lowe (Vice-President) in the chair.—Mr. E. J. WALL gave a discourse on the *Latest Novelties*. The first article under notice was a metal holder, for lantern slides on celluloid films, followed by little oval copper plates, covered with a special composition for transferring the pictures, and completing the process by firing the plate. Mr. Wall then showed a German lens which was remarkable for its covering power and depth of focus. He showed several large direct photographs bearing out these qualifications. This was followed by some examples of colour printing, which had been making rapid progress of late, and some very fine specimens of Collotype printing, as used for book illustrations. Mr. Wall stated that an Austrian photographer had recently published a formula whereby by printing on gelatino-chloride paper until all the details were just showing, and then developing the picture up before toning and fixing, a great saving of time was the result. The final "novelty" was a few remarks on the toning of bromide paper, using, instead of the uranium toning bath, the old lead intensifier. By using this, almost any colour could be obtained.

North Middlesex Photographic Society.—March 14, Mr. S. E. Wall in the chair.—Mr. WALKER delivered a lecture on *Photographic Procedure in the Dark Room*, and carried his audience through the whole process of negative-making, from the exposure of the plate to the final drying of the negative. Touching upon the principles involved just sufficiently to make his meaning clear, he dealt minutely with all points of practice, the qualities of various developers, and their peculiarities, the method of compounding the developer, and gave as his favourite—Pyro, one ounce; meta-bisulphite of potash, half ounce; water, up to ten ounces. This he considered an admirable developer for amateurs working at irregular intervals, as it would keep indefinitely free from discolouration. Meta-bisulphite was said to act as a restrainer, but he thought that an advantage to a beginner. He used the bromide and the ammonia in ten per cent. solutions, and mixed the developer in the proportions of grains to the ounce given by the makers of the plates, but, in cases of uncertainty as to exposure, kept the strengths of all the chemicals slightly weak, till the tendency of the plate was known. He then dealt with under and over-exposure, giving careful and minute advice as to procedure. Frilling, halation, and a number of other pitfalls were considered, and advice given. At the last meeting packets of bromide paper, sent by the Eastman Company, were distributed among the members. The prints made upon them were now shown, and questions as to difficulties met with were asked and answered. Some of the prints were very fine, great atmospheric effects having been obtained. Twenty-four packets of plates, sent by the Imperial Plate Company, were distributed among the members to be tested, also copies of exposure tables, sent by Mr. Manox. A beautiful print of ice crystals, given by Messrs. Martin & Co., was passed round for inspection; the crystals had assumed a wonderfully harmonious design of fern fronds and flower forms. The next meeting will be held on March 28, when Mr. Beadle will demonstrate on *Enlarging by Artificial Light without the Use of a Lantern*.

THE annual dinner of the Society took place at Beale's Restaurant on Saturday evening last, the President (Mr. J. W. Marchant) in the chair. Between fifty and sixty were present. The toast of the Society was proposed by Mr. E. J. Wall in an eulogistic speech; and Mr. J. Traill Taylor responded for "the Press." Mr. Walker and Mr. McIntosh spoke to the toast of "the Officers." The gathering was enlivened by music of a high class, and an excellent evening was passed.

West London Photographic Society.—March 11, the President in the chair.—Mr. HOWSON explained the new Ilford isochromatic plate, and performed experiments demonstrating the advantages of colour-sensitive plates over ordinary ones for a great variety of subjects. He also described the new Ilford screen, which consists of a metal framework, easily fixed on the inside of the camera front, into which the screen may be inserted in a moment, or as quickly taken out when an ordinary plate is to be used. He mentioned that in most cases a light tinted screen was required; at sunset, sunrise, or in hazy weather, it was not so much needed, because the atmosphere itself acted as a screen, and there was no excess of blue light to modify, but that for ordinary landscape work a screen was always more or less an advantage. He adverted to the necessity of having the screens perfectly optically ground, to prevent distortion, and also that they should be tested by a spectroscope, as it was probable, if these precautions were not taken, that they might get a screen that did more harm than good; also that care should be taken not to use too deep a tint of glass, or over-correction might result. In answer to questions, Mr. Howson stated that their isochromatic plates were made under a licence from Mr. Edwards; that they had a distinct advantage over ordinary plates in respect of halation, although he did not profess it could be altogether eliminated; and, replying to a question by Mr. Whiting as to whether there was not a disadvantage in taking landscapes when the effect of atmosphere and distance was required, and whether isochromatic plates did not penetrate through the haze and give too sharp an image, he stated in his opinion an ordinary plate sometimes gave too great a mistiness in the distance, and did not render the values correctly. Mr. WHITING thought that using coloured screens shortened the focus of the lens, but Mr. HOWSON said, if properly ground, he was under the impression it was not so, and Mr. ROGERS thought perhaps the solution was that the yellow rays had a different focus to the white rays. Mr. HODGES mentioned the fact that isochromatic plates had a tendency to give undue density, unless the exposure was ample.

Tooting Camera Club.—March 10.—The following officers for the ensuing year were elected, viz.:—*President*: Mr. A. H. Anderson.—*Vice-President*: Mr. J. H. Beckett.—*Committee*: Messrs. H. Berger, J. F. Child, J. A. Collingwood, W. Irwin.—*Treasurer*: Mr. C. E. Stowell.—*Secretary*: Mr. G. D'Arcy Glies, Lucien-road, Tooting Common. A communication was read

from the Hon. Secretary of the Brixton and Clapham Camera Club with reference to a proposed joint exhibition by the societies in South London, and a sub-committee was appointed to deal with the matter. Next ordinary meeting, April 7: the President will exhibit members' slides by means of his lime-light lantern.

Croydon Microscopical and Natural History Club (Photographic Section.)—March 11, Mr. W. Goode in the chair.—The Chairman showed a self-adjusting tripod made of bamboo, the tripod head having a ball-and-socket movement, with a plum-bob suspended underneath to a length of wire, this arrangement bringing the top of the joint perfectly level, it being afterwards made fast by the tightening up of a screw at the side. Mr. GOODE, in opening the subject for the evening, *Exposure and Actinometers*, said he thought experience went a long way with regard to correct exposure. Makes of plates varied very much in rapidity, and, when good results were obtained by any particular plate, it should be kept to. Mr. WEIR BROWN gave a description of exposure tables, and method of simplifying, and it was found that very little difference existed in the different tables in use. Through the kindness of Messrs. Adams & Company, Messrs. Hurter & Driffield's exposure meter, and Watkin's actinometer, were shown and described.

Richmond Camera Club.—March 11.—Mr. Clarke, of the Incandescent Company, read a paper explaining clearly the principles and advantages of the Welsbach system, and its application to ordinary house gas and oil gas. The apparatus for producing the latter from spirit of paraffin was exhibited and explained, and some lantern slides were afterwards shown by the aid of the light which, though, of course, much inferior in power to the oxyhydrogen light, was seen to be greatly superior to the oil-lamp in point of whiteness of light and evenness of illumination.

Birkenhead Photographic Association.—March 10.—One hundred and fifty lantern slides, taken by the late Dr. Arnold, when in Norway last year, were exhibited. Messrs. F. N. EATON and E. M. TUNSTALL introduced the subject of Mr. Stead's *Magic Lantern Mission*. A discussion followed, resulting in the formation of a committee to further its interests.

Derby Photographic Society.—March 8.—Mr. A. R. Dresser sent for reading a lecture on *Brittany*, illustrated by 200 lantern slides. The negatives from which the slides exhibited were photographed were all taken instantaneously with a camera held in the hand, the remarkable sharpness of outline, and width of detail of the originals, rendering the slides taken with them perfect pictures. Another series of slides by the same gentleman, animals, &c., taken at the Zoo, were also exhibited, as also was a set showing a dog taken whilst jumping in mid-air.

Leicester and Leicestershire Photographic Society.—March 9, Mr. Frank G. Pierpoint in the chair.—Lantern Slide Competition.—There were nine competitors. The Judging Committee consisted of Messrs. Pierpoint, Scotton (Derby Photographic Society), and Porritt. The results were that the first, or silver, medal was awarded to Mr. George Bankart, and the second, or bronze, medal to the Hon. Secretary, H. Pickering. The slides sent in were of exceedingly high merit, as may be conceived from the fact that only two points separated the first, second, and third exhibitors, Mr. Joliffe running the Hon. Secretary very hard for second place, and it is confidently believed that the final selection will give general satisfaction. Mr. Pierpoint being an old and practical lantern-slide operator, as also Mr. Porritt, while they were fortunate in securing the services of Mr. Thomas Scotton, who is an hon. member of the Society, and holds the responsible position of photographer to the Midland Railway Company.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

BINOCULAR APPARATUS FOR VIEWING LANTERN SLIDES.

To the EDITOR.

SIR,—On February 8 last I called at No. 2 York-street, and submitted to you a binocular apparatus for viewing lantern slides, fitted with prismatic lenses arranged in a certain way which I had designed and constructed, and asked you in a friendly way, knowing your long experience, whether it were possible to obtain a valid patent for it. It therefore seems somewhat strange to me, taking the above facts into consideration, that in your leading article in your last week's issue, more than a month after, you should have entirely ignored the apparatus exhibited to you by me, believing, as I do, that it was the first practical apparatus of the kind that had been constructed.—I am, yours, &c., BIRT ACRES.

Clifton-villa, Ilfracombe, March 15, 1892.

[The facts set forth in the first paragraph of our correspondent's letter are beyond dispute, as indeed is the further one (which he apparently forgets), that we assured him that it was *not* possible to obtain a valid patent for the binocular lanternoscope. We are not in the habit of culling subject-matter for our leading articles from the communications of those of our friends who may seek our advice, otherwise in the article referred to we should not only have felt constrained to notice Mr. Acres' binocular apparatus, but also a very beautiful one, constructed on identical principles, which Mr. Fox Shew exhibited to us some months ago. The idea, as we informed Mr. Acres, is not new. It was adopted by Mr. George Mason just prior to the Chester Convention, circumstances, however, preventing him from placing it on the market. A model of Mr. Mason's lanternoscope has been in our possession ever since that time. It was fully described in a contemporary early in 1890, in these pages during the the year 1863, and again in the same place in 1884. Mr. Acres will thus clearly see that he has been anticipated over and over again, a matter upon which, at the interview referred to, he failed to question us. Our advice upon the value of "new inventions" and "ideas" is sought daily. Does Mr. Acres hold it a matter of duty with us to travel outside the questions put to us in his own and the numerous other cases to which we have alluded, and gratuitously constitute ourselves a living encyclopædia of what has been achieved and attempted in the path of photographic invention? Does he also conceive it to be our mission to interfere between *soi-disant* inventors and the trade with the object of dissuading the latter from enjoying the luxury of tendering handsome cheques in exchange for old, if ingenious, optical devices?—ED.]

RATIO OF GRADATION.

To the EDITOR.

SIR,—I think that "Free Lance," in your issue of the 4th inst., is over-hasty in his conclusion that Messrs. Hurter & Driffield betray ignorance of their own work. He quotes from page 6 of their article, after which follow tabulated results of long and short development by the same developer. They remark that these results show that the ratio is not affected by the *time* of development. They then draw attention to other *following experiments*, to show that "no modification in the developer ever seriously disturbed this ratio." They point out, however, that eikonogen gave slightly different results; and at the close of the paper they advert to the theoretical possibility of different developers acting diversely. Bearing this in mind, I think that their statement, "This ratio, we find, is *altogether* unalterable" (the italics are mine), need not mislead any careful reader as to their real meaning, that they have only succeeded in obtaining a trivial amount of difference by the most diverse modes of development. I think that Messrs. Hurter & Driffield's explanation of their own views might be accepted without the discourteous retort to which I have alluded. "Free Lance" gives it as his opinion that the ratio can be changed at will; but will he undertake to do so, give his results, and describe his mode of operation?

It is to be regretted that Mr. Bolton has not read the original paper, which appeared the year before last in the *Journal of the Society of Chemical Industry*, in March or April, I think. He would have seen that he is mistaken in supposing that only "normal" exposures and developers had been used, or that development was pushed to its limit in all cases. To deal with all the points where he is at issue with the authors would need a long article; but I may point out that a uniform fog, which would convert the series 0, 2, 4, 6, 8, into 1, 3, 5, 7, 9, is not the action of *light* on the film as understood by Messrs. Hurter & Driffield, and its only effect would be that the latter negative would require ten times more light than the former to produce an identical positive (according to the unit-density employed by Messrs. Hurter & Driffield).

The important point raised by Mr. Channon in the JOURNAL of March 11 is answered by these gentlemen on pages 1 and 2 of their paper:—

"These relations hold good for some substances with regard to ordinary white light, for others only with regard to monochromatic light, and for others they do not hold good at all. We have satisfied ourselves that they do hold good for the silver deposited as a black substance in negatives, so long as the silver does not assume a metallic lustre and reflects but a very small amount of light."

In a subsequent communication to the Society of Chemical Industry, they give the following numerical results:—

"Four half-plates were exposed and developed to different densities. They were then measured in different places, and the densities averaged. After that, the films were taken off, treated with nitric acid, the silver precipitated with hydrochloric acid, filtered and weighed on a fine balance. The adjoining table gives the results:—

Plate No.	Density found.	Grammes Ag Cl found.	Density calculated from Ag Cl.
1	0·525	0·0163	0·525
2	0·960	0·0299	0·963
3	1·470	0·0450 .	1·449
4	1·970	0·0611	1·968

These figures will, I think, satisfy Mr. Channon of the correctness of the author's results at reasonably low and moderate densities. It may be worth while, however, to point out that a plate of the above character, whose film possessed the greatest transparency tabulated by him, would have an opacity of 1·1057, and therefore a density of 0·044 only. The unit of silver would be 0·0014 grammes per quarter-plate. It will be seen that these figures are less than a tenth of the smallest amounts dealt with by Messrs. Hurter & Driffield; indeed, the glass and film of pure gelatine of an ordinary negative absorbs much more light. Probably these quantities are altogether outside the limits under which Messrs. Hurter & Driffield have satisfied themselves that their stated relations hold.

I should esteem it a favour if any correspondent would inform me where Captain Abney's research connecting the density with the law of error is to be found, as the original paper has not fallen under my notice.—I am, yours, &c., R. C. PHILLIPS.

Arts Club, Manchester, March 11, 1892.

WHAT ABOUT ORTHOCHROMATIC PLATES NOW?

To the EDITOR.

SIR,—Some time ago, if I remember rightly, there was a correspondence in THE BRITISH JOURNAL OF PHOTOGRAPHY between Mr. Andrew Pringle and another gentleman whose name I have forgotten, bearing upon the merits and demerits of isochromatic plates for landscape work, Mr. Pringle asserting hot and strong ("at least, so a bystander would assume"), that "iso" was a bubble, and the other gentleman, equally confident in his opposite conviction, stuck up manfully for his opinion being the correct one.

After some rather hot words and "funny man" business, "a challenge was given and accepted, that each advocate should take a competition trip together, and the result of each should be judged by an impartial "jury."

I believe I am correct in my opening address. Now for my side of the question. I am totally unacquainted with any maker of plates whatsoever, neither have I any interest directly or indirectly with photography as a trade, and therefore I have no object or interest except one, of *progress*, when I ask the question, did the match referred to ever come off? if it did do so—and I presume "*it must have done*," after so public a challenge—what was the result?

I note that Professor Bothamley, and Mr. Howson, and others consider that iso or orthochromatic plates are, under certain circumstances ("and *these more than less*"), a great power in the hands of the photographer.

The photographic season is about to commence again, and I dare say hundreds, like myself, would like to know whether there is any advantage in using colour-sensitive plates or not. It is a topic that, at the present juncture, possesses great interest to every one who carries a camera, for "good work" is becoming more the order of the day, and now that colour-sensitive plates have cheapened, and are within the reach of all, it is perhaps not out of place to lay my queries before my brother tripods.—I am, yours, &c., VERITAS ET VERITAS VINCUNT.

March 15, 1892.

DEPTH OF FOCUS.

To the EDITOR.

SIR,—There seems to be a somewhat important omission from Mr. Bennett's remark on depth of focus. It can be readily shown that the distance (E F) between the focal planes is $EF = Kf^2$ where K is a constant as long as the distances of the two objects are unaltered. Also that the diameter of the circle of confusion is $a = Kfd$, where d = diameter of the stop = $\frac{1}{8}$ inch hyp. Hence, if K is the same for both lenses, we have for the 20-inch lens E F = 400 K, for 5-inch E F = 25 K; hence, if E F is 1 inch in the first case, it is $\frac{1}{16}$ in the second. Again, for 20-inch lens $a = 5$ K, for 5-inch $a = \frac{1}{8}$ K, hence the first circle has its diameter four times that of the first. But, if the camera is so placed with the 5-inch lens as to take the image the same size as with the 20-inch, K is different in the the two cases, and becomes 4 K for the 5-inch lens.

We therefore have, for 20-inch, $EF = Kf^2 = 400$ K;
and for 5-inch, $EF = 4Kf^2 = 100$ K.

So, as in Mr. Bennett's case, 1 inch becomes $\frac{1}{4}$ inch.

Also, for 20-inch, $a = Kdf = 5$ K;
5-inch, $a = 4Kdf = 5$ K.

And in this case the circles of confusion are equal.

It appears, therefore, that only when the images taken by the two lenses are equal is it true that the depth of focus depends simply on the actual diameter of the stop.

I have considered the distances to be great compared with f, as the expressions are much simplified thereby.—I am, yours, &c.,

Glenfall Lawn, Cheltenham. CLIFFORD E. F. NASH.

THE ARTIST: HIS EVER-WIDENING SPHERE.

To the EDITOR.

SIR,—I was wheedled last Saturday morning into reading your Manchester multiple artist's letter by the grand heading at the top of it. I hammered through the wordy epistle until I came to the nugget: "If the photograph was the best specimen ever produced, and the water-colour drawing the worst, the one is still a mechanical production, and the other a work of art." Then my heels went up in the air, and ——

You see, sir, I was, and still am, under the impression that any one is an artist who can produce pictures in any medium and by any method. The unveiled face of nature is, doubtless, not always pictorial, but then, as the cloud shadows sweep over the scene, the artist feels their most effective position in the landscape; and, whether he stands with a palette on his thumb or an air-charged ball between his fingers, he may, by the continuance of his thought and labour, produce an eye-attracting, yea, even a mind-moving representation of the scene he had witnessed. Grand old David Cox, on seeing an effect on the landscape before him, turned his back on it, and pencilled instantly on his block the impression he had poetically received; and so, surely, may the photographer flash on his tablet any effect when it touches him to the quick.

I would not for a moment think of placing the artistic expression of a landscape by, say, Hook or Peter Graham, within reach of a photograph; but to say that a photograph may not also be a true work of art, and the work of an artist, would suggest the possibility of one's sense and sight having become fossilised, or worse.—I am, yours, &c., J. P.

Edinburgh, March 14, 1892.

BLUE PRINTS.

To the EDITOR.

SIR,—I do not know whether the enclosed is a novelty, but it certainly is such to me. The print is printing out platinotype, which I meant to tone brown with uranium.

Usually, I use nothing but rain water for photographic purposes, but, owing to my tank being frozen, the print was washed after the usual acid (HyCl) bath, in well water, which contains a considerable quantity of iron.—I am, yours, &c., H. G. M. CONTREARE.

The Hut, Ingatestone, March 13, 1892.

THE CAMERA CLUB CONFERENCE.

To the EDITOR.

SIR,—Will you kindly allow me to remind your readers that the annual photographic conference organized by the Club will be held at the Society of Arts on Tuesday and Wednesday, March 22 and 23, from 3 to 6 p.m., and 8 to 10 p.m. on the Tuesday, and from 3 to 6 p.m. on the Wednesday.

As there seems to be some misunderstanding on the point, I should like to state that the meetings for reading of papers and the discussions are open to all, and no tickets of admission will be required.

The full programme has already been given in your pages. A copy of this programme will be sent to any one desiring same. A slight alteration will be made in the Wednesday's arrangements, Mr. H. P. Robinson's paper coming on at 3 p.m., and Mr. Henry Blackburn's at 4.30 p.m.—I am, yours, &c., G. DAVISON, *Hon. Sec.*

Camera Club, Charing Cross-road, W.C.

THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

To the EDITOR.

SIR,—I have the honour to inform you and your numerous readers that the next Photographic Convention of the United Kingdom will be held in Edinburgh on the week beginning on the 11th of July proximo. The hall of the Geographical Society in the National Portrait Gallery in Queen-street, Edinburgh, has been secured for the meetings. Later on I shall have the pleasure to send you fuller particulars of papers, excursions, &c. In the meantime I shall be glad to receive the names of intending members.—I am, yours, &c., F. P. CEMBRANO, JUN.

10, *Cambridge-gardens, Richmond, Surrey, March* 10, 1892.

MR. FRY'S ENLARGING LANTERN.

To the EDITOR.

SIR,—I am not content to acquiesce in Mr. Clarke's easy description of *my* system. There are variations in principle and detail between Mr. Armstrong's method (as I read it in the pages of the BRITISH JOURNAL OF PHOTOGRAPHY, and as described by you) and mine, which go to make a vast difference in practice. The insertion of the word *not* between "was" and "exactly" in the sentence attributed to Mr. Clarke would, however, quite satisfy me; and as it is such a slight addition to the text, probably he won't object.—I am, yours, &c., S. HERBERT FRY.

The Fry Manufacturing Co., Photographic Works, Kingston-on-Thames, March 15, 1892.

KEEPING CHLORIDE OF SILVER.

To the EDITOR.

SIR,—It may be a useful hint to some of your readers to recommend them to store precipitated and dried silver chloride from print washings in glass jars. A few months ago I put a few ounces into a tin canister, and, on handling it the other day, the top of the box came away, leaving its lower half on the shelf in a deliquescent mass of what is presumably mixed chlorides of silver, tin, and iron. How can I separate and get rid of the tin and iron?—I am, yours, &c., H. K.

March 15, 1892.

[Simple washing in warm water will in all probability remove the iron and tin salts if such have been formed.—ED.]

Exchange Column.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," *2, York-street, Covent Garden, London.*

L. S. D.—We should give choice to the six-inch condenser.

J. JONES.—1. Filter the solution. 2. Fresh eggs are preferable.

SELF AND ARMSTRONG.—Our publishers will copyright the picture for you at a charge of 1*s.* 6*d.*

H. J.—Dr. Miethe, Editor of the *Photographisches Wochenblatt*, Berlin, will be sufficient address.

E. D.—Mr. Fallowfield, we believe, publishes a work on ferrotype, which is probably what you require.

F. SIMPSON.—Any wholesale druggist, or perhaps your chemist, will supply you with Venice turpentine.

Dr. A. C. MERCER.—Many thanks. We were unable to be present, but should be pleased to have further particulars.

W. JONES.—The particulars of your Society came too late for the ALMANAC. They appear in the JOURNAL for January 8, 1892.

INQUIRER.—If by "a useful and inexpensive material for outside showcase" you mean a background for the case, select a dark red velvet.

J. ROBINSON & SONS.—Messrs. A. Macnair & Co., Dalton-street Distillery, Manchester, are the firm who offer to supply methylated spirit of the old kind.

JOHN O. CAMPBELL.—1. Consult the catalogues of the various makers, which will be sent you on application. 2. About eleven-inch focus. 3. See answer to No. 1.

A. Z.—The best account of the very earliest processes of photography is to be found in Hunt's works on photography. They are all out of print, but may frequently be met with at bookstalls.

S. A. J. wants some paper prepared ready for Woodburytype printing, and says he is told that it cannot be had in England. Some little time ago, Messrs. Marion & Co. wrote, saying that they supplied it. Write to them.

W. A. T.—1. A rapid wide-angle lens, or any rapid wide-angle lens, say, of the Voigtlander wide-angle Euryscope type, will answer the purpose. 2. A lens of the rapid rectilinear type, which can also be used for landscape work.

W. H. C.—1. Imitation ground-glass effect may be produced by dabbing over the surface of the glass with putty. 2. Beckman of Cowcross-street, or Schulze of Long-lane, will supply you with mouldings for picture-framing.

SPECIMENS.—We have no sympathy whatever with appropriators of specimens. Write and tell the man that if he does not return your specimens by a given time you will communicate with the chief superintendent of the police in his town.

R. BLACKWELL.—There is no copyright in Hogarth's original engravings; lantern slides were made from them, and sold commercially, thirty or more years ago. If any copyright is claimed, it must be for particular reproductions of them.

ORPHAN.—Do not spend, or rather waste, your money or time on learning crystoleum colouring with a view to making a livelihood by it. No photographer would give you employment, as he would not tolerate the best of such work on his premises.

MOUNTINO asks: "Will you kindly tell me what you consider the most practical and best way of mounting photographs in an album with cardboard leaves to prevent cockling? Can thin glue be used safely?"—Yes, but the glue must have a considerable addition of alcohol.

D. EVANS.—Photo-lithographic transfer ink can be obtained at all the dealers' in lithographic materials. Ordinary lithographic presses are used in photo-lithography. The difference between photo-lithography and photo-zincography is practically none, except that a zinc plate is employed instead of a stone.

H. SHARMAN says: "In all accounts I have read of the collotype process, a drying box is spoken of. Is such a thing absolutely necessary? Would not an ordinary room answer the purpose?"—Yes, if the temperature be regulated exactly to kind of printing plate desired. The temperature at which a collotype plate is dried is an important matter. This being attended to, it is of no importance whether the drying is effected in a box or a room.

C. BENNETT inquires: "1. Can you tell me the best and simplest way to make *papier-mâché* accessories, such as a pedestal, &c.? also how to make the moulds? 2. Next to a north light, which is best, east or west?"—1. Space is far too limited in this column to give practical details on such subjects. 2. If the major portion of the work is done in the morning, a west light is the more convenient; if in the afternoon, the opposite, as then direct sunlight is avoided.

SOLICITOR.—This gentleman, who has just taken up photography as an amateur, says that he is concerned for a client in a dispute as to the value of an estate. The opponents have had some photographs taken, which they intend to show at the trial of the action, that quite misrepresent the property. He wishes to know if he can do anything in the interest of his client to combat these misleading photographs?—Our correspondent does not say in which direction the photographs are misleading, exaggerating, or the reverse, so that we cannot advise definitely. We should consult an experienced photographer, telling him that he required pictures conveying the opposite idea to those already taken.

AMATEUR writes: "I beg to inquire of you whether you know of an enamel which is used to fix photographs upon porcelain or china previous to putting same in the oven, and also what degree of heat is required?"—This query is very vague. By "enamel" we assume that *glaze* is meant. If so, this is supplied by those who sell ceramic colours to fuse at different temperatures. If our correspondent atatea his requirements to the dealer, he will supply what is required.

C. W. GASKELL (Dresden) says: "I shall be much obliged if you would tell me a good salting bath for plain drawing-paper in your next issue; also what strength of silver bath to use. Should like the formulæ in grammes." Much depends upon how the solutions are applied, as well as on the porosity of the paper. If the papers be immersed, much weaker solutions must be used than when they are salted by floating. If the paper is tolerably hard and floated, a solution of chloride of ammonium of about twelve grammes to the litre of water will answer. The sensitising solution should be about eight times this strength. But experiments will have to be made in order to see the proportions that best suit the particular sample of paper that is employed.

C. ROSE says that he has made some bromide paper by a formula that has been given for rapid plates, and cooked the emulsion for the same time. He complains that every sheet he has exposed yields flat pictures. The image flashes out directly the developer is applied, although in some cases he has reduced the exposure to one-third that he gives with a rapid commercial paper. Also that the image does not keep on the surface, but appears more as it is in a negative. There are two sources for the trouble; one is, that the emulsion is far too sensitive, very much over-cooked—an emulsion that, if applied to glass, would be very slow, on paper would be very rapid. The other is, that the emulsion is far too rich in silver. Very little bromide of silver is necessary in the emulsion when it is applied to paper for positive pctures.

P. O. P. writes: "Will you, through the medium of your columns, tell me of auything that will stop the toning of the gelatino-chloride priuts, when in the washing water, that will not also be injurious to the print? I find, on toning a batch of the prints, considerable allowance must be made for after-toning, as the toning continues until the prints are quite blue even thongh they are placed in constantly running water. Of course, if all were toned at one time, we could allow for this; but, in toning a quantity, some must of necessity wait longer than others, and so tone further in the washing water. If you can give me any assistance, you will oblige."—There is nothing that will immediately arrest the toning action without injury to the print but removing the solution from the print. This can be done by washing the print under a strong stream from the tap. In practice, however, if the prints have to remain long before fixing, allowance is made by slightly under-toning them in the first instance.

THE PHOTOGRAPHIC CLUB.—March 23, Last Lantern Night of the season. March 30, Smoking Concert.

THE Blackfriars Photographic and Sensitising Company have issued a Purse Camera, which, as implied by the name, packs up in form of a purse. It is not intended to compete with cameras of the usual class.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—Technical Meeting, March 22, 8 p.m., exhibition of old silver prints. Mr. Dallmeyer will show his telephotographic lens. Mr. Chapman Jones on *Copying Inclined Pictures.*

WE are sorry to hear of the death of Mr. Henry Newton, of Liverpool, which occurred on Saturday last, after an illness of six months' duration. Mr. Newton was one of the oldest photographic dealers in the country, and was much esteemed in the trade, and by a large circle of friends.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—March 24, *Continental Photographic Institutions and their Influence*, Mr. W. H. Harrison. Mr. Warnerke will take the chair, and exhibit his lantern slides bearing on the subject. 31, *Photography on Wood.* By W. S. Rawlings. April 7, *Collodio-Bromide Emulsions*, Mr. Alexander Mackie.

MESSRS. HOLMES, SADLER, & HOLMES writes: "In your reply to 'Sined,' in 'Answers to Correspondents,' March 11, you say, 'So far as we are aware, Mr. J. J. Atkinson is Seavey's sole agent.' Please note that we are agents, and claim to hold the largest stock of any English house. Messrs. G. Mason & Co., of Glasgow, are also Seavey's agents."

WE understand that Mr. Gambier Bolton, recently attended at Windsor Castle, and presented to the Queen five framed photographs of dogs in the Royal kennels, the Egyptian ass, presented by Lord Wolseley, and the celebrated champion short-horn bull, "New Year's Gift," recently sold from Shaw Farm, Windsor Home Park, for one thousand guineas. Duplicate copies of these will be hung in the Camera Club Members' Exhibition during the approaching conference.

CONTENTS.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1664. Vol. XXXIX.—MARCH 25, 1892.

GLASS POSITIVES AND FERROTYPES WITH GELATINO-BROMIDE.

Although the glass positive seems to have sunk out of mind with the wet-collodion process, while its more modern imitator, the ferrotype, finds its principal patrons amongst seaside excursionists and the like, there is no possibility of denying the beauty of the results obtainable in skilful hands by either of those methods; and there are in existence at the present time specimens of the collodion positive, or "ambrotype," as it was called in America, the work of one or other of the "old masters" in collodion, which would put to shame, for quality, very much of the work turned out with all our modern advantages, and which, in their delicacy of gradation and beauty of colour, are scarcely distinguishable from Daguerreotypes.

Of course, it is scarcely needful to say that there were positives *and* positives, and that, though the best workers were able to turn out specimens that would vie with the results of any process past or present, still a great deal of the work scarcely passed mediocrity, while another very considerable portion would have been better had it never appeared; and, unfortunately, it is on the inferior results that the reputation of the process now chiefly rests. But, even granting the superior quality of the work it is possible to execute, it may be asked what benefit is to be gained by reviving the glass positive, even if it could be satisfactorily achieved with gelatine films.

The reply is not difficult, especially from a professional point of view. There are very many people who would go to the expense of a single portrait but who do not care for, or have no use for, more, especially if that one could be finished and taken home at once instead of their having to wait a week or two "for proofs." It is true that so far as the single picture is concerned the difficulty is surmounted by some of the professionals who cater for the humbler classes. These gentry will supply a single *carte-de-visite* or even cabinet portrait at a price little in excess of what used to be charged for the glass positive or ferrotype, but no one who knows anything about the cost and labour of production will believe that such work can be well and honestly executed, to say nothing of its artistic quality. Now, a glass positive, on the contrary, can be well and fairly executed for a small sum, and the artistic quality of course depends solely upon the executant.

Even to the amateur the glass-positive idea is not without its recommendations. Who amongst our amateur readers is not blest with friends—friends innumerable—who would rejoice in being photographed "without the bother of going to a regular photographer!" The "regular photographer" has got himself disliked by his generally autocratic manner, but chiefly, as far as we can gather, from his habit of screwing his victims' heads up in the "rest." So at least they say, and of course we cannot suggest that his necessary fee forms any objection to him, but certain it is that the amateur could secure unlimited customers either from the abolition of the head rest or else of "all fees." The good-natured amateur soon finds this sort of thing a tax upon him, not perhaps so much in a pecuniary sense, for he is bound to ride his hobby, but on account of the labour it entails upon him. The production of the negative is the least onerous portion of the duty, it is the after-demand for prints that constitutes the grievance. Now, if he were to institute the system of "reproducing" his friends in the form of glass positives, there is practically an end of the trouble. He has the amusement and pleasure of his hobby, and, at the same time, of conferring an obligation, and he gets the matter out of hand at once without any after-anxiety in the matter of prints.

But then arises the question, Can I make glass positives on gelatine plates? Well, so far as ordinary gelatine plates are concerned, it is generally supposed to be impossible; but there are films on the market now, in the form of ferrotype plates, we believe, which are specially prepared for positive purposes. However, after all, it is not quite impossible to utilise many of the ordinary commercial plates, and to produce results which, if they do not equal the best examples of collodion positives, are at least good enough to pass muster in very respectable company.

What is wanted first of all—and this is important—is a plate that will develop without any sign of fog or veil. In this respect the positive, to be viewed by reflected light, is even more *exigeant* than its congener, the transparency, in viewing which, by transmitted light, a slight veil may be imperceptible. Not so with the positive by reflection; the very faintest veil destroys the brilliancy of the picture irretrievably. This first condition is almost necessarily followed by another, namely, that the plate must be a comparatively slow one. This is not only because the more rapid plates are so seldom perfectly free from fog or veil, but because, with an extremely rapid plate, it is, in the highest degree, difficult to prevent the sensitive surface being more or less affected by light in the deepest shadows, and consequently the contrast and brilliancy requisite are not obtainable.

With many of the slower kinds of plates already in the market there is, however, very little difficulty in securing a good result if a little care is taken. It is, as already noticed, usually supposed that a special plate is necessary; perhaps, to obtain the best results, or to get ordinarily good ones with as little trouble as possible, a special plate may be desirable, but a very great deal may be done with an ordinary plate if special means be taken.

In the first place there is the matter of exposure. In the old collodion days, the exposure of a positive was much less than that given for a negative under similar conditions. But

this is scarcely the case with gelatine. A sufficient exposure must be given to allow the high lights of the picture to develop up to a certain degree of density before the shadow details begin to gather strength. If the exposure is too much curtailed, the lights will come up slowly, and, in pressing the development to get out the finer details, the plate becomes veiled; if over-exposed, the shadows fill up before the lights have attained vigour enough. The rule, then, is—more so than in the case of a negative—absolutely correct exposure, no "latitude."

Next, everything depends upon the colour of the deposit, and this, in turn, on the development. The stronger the developer, as a rule, the darker or more unsuitable will be the surface colour of the deposit; and, conversely, the weaker the solution—so far, at least, as the actual reducing agent is concerned—the lighter or more "silvery" will be the tint, although, of course, different plates or films vary very much in this respect. For instance, plates in the preparation of which potassium bromide has been used show, as a rule, whiter or lighter images than those prepared with ammonium bromide, and films containing iodide usually exhibit a tendency in the same direction. Thus it may happen that, while one plate requires a one-grain pyro solution to give a fair result, another may give a better image with three grains, though this is not a very common occurrence with modern plates.

Of the different developers, the choice lies between pyro, eikonogen, and the newest addition, para-amidophenol. Hydroquinone, when used in sufficiently dilute solution, is so slow in action as to be placed practically *hors concours*, unless, indeed, it be combined with caustic soda, in which case it is difficult to get the necessary clearness. In using pyro it is, of course, almost, if not quite, absolutely needful to employ sodium sulphite, otherwise the yellowing action of the developer upon the gelatine will inevitably detract from the beauty of the resulting image, if it do not altogether spoil it. A slightly "creamy" tint is by no means an objection, but rather an improvement, but the colouration produced by pyro is widely removed from that shade. With sulphite of soda, however, the pyro-developed image possesses a creamy whiteness and brilliancy combined that can scarcely be equalled—certainly not excelled by any of the newer developers. It also, under the most favourable conditions, exhibits a collodion-like "bloom" or tint, that is entirely absent from eikonogen or phenol-developed images.

The strength of the pyro, for most of the plates of the class we have mentioned, need not be greater than one grain to the ounce, the alkali remaining the same as for a normal negative exposure, and the bromide being, if anything, slightly increased. The alkali may be either ammonia or carbonate of potash, but under no circumstances carbonate of soda, on account of the yellow colour it produces. Potash gives possibly a whiter image than ammonia under all or any circumstances, but under specially favourable conditions the better, or rather the very best, results are obtained with ammonia.

The exposure, as already stated, should be ample, but not too long, and the development should be continued until the details of the shadows are clearly visible, but not long enough to tint the deepest shadows themselves. If this occurs before sufficient vigour has been obtained in the details, or if the high lights should come "heavy," it will be necessary to use more bromide, or better still, if applied with judgment, a drop or two of a ten-grain solution of bichromate of potash, which has a very powerful clearing action. Another expedient of the same kind which, from the few trials we have made of it in this as well as other connexions, consists in adding to the developer, instead of bromide, a similar quantity of sulphate of copper, the action of which is as follows:—As development proceeds, and the silver bromide is reduced, bromine is liberated, which combines with the alkali of the developer to form bromide of ammonium, or potassium, as the case may be, both of which are restrainers, and nothing more. In the presence of the copper salt, however, these, if formed, are at once robbed of their bromine, bromide of copper being formed; and this salt is not only a restrainer, but a destroyer of the latent image. By the use of sulphate of copper in the manner suggested, we may then start development without any restrainer—for the copper salt is comparatively, if not wholly, inert—and in proportion to the progress of development so is a powerful restrainer formed, which at a certain point will arrest development altogether. This is a capital plan for treating over-exposure, but must be used with great care. It is only applicable with pyro, and succeeds best when ammonia is used.

Development with eikonogen and para-amidophenol presents no features to distinguish it from pyro, except in the character and colour of the image. The same rules hold good, namely, weak developer, well restrained, and a good exposure.

MOISTURE AND HEAT IN CARBON PRINTING.

In a previous article on the effect of moisture in carbon tissue (see page 162, *ante*), the importance of its hygroscopic condition was fully explained, in so far as it referred to sensitiveness and keeping qualities. There is, however, another point in connexion with carbon printing where the presence or absence of moisture is an important element in the process. We refer to the so-called "continuating action of light." This somewhat remarkable property was noticed by the very earliest workers of the process. It is now tolerably well understood by most carbon printers, whether professional or amateur, that if a carbon picture is not developed as soon as it is printed it gradually gets deeper, notwithstanding that it is preserved in the dark. Hence, if prints have to be kept for some hours before they are developed, they should receive less exposure than if they were to be finished off at once.

For some years this progressive action was denied by some writers on the Continent, while here it was as strenuously affirmed. It is now, however, universally recognised everywhere, and great advantage is taken of it by professional printers to obtain large numbers of impressions from a given negative in short time during the winter months. For a long time, however, after the property was fully recognised, but little use was made of it, because of its apparent uncertainty. Sometimes it was found that the partially exposed prints would gain as much in a few hours as they would at others in days.

It was afterwards noticed that, when the printed tissue was freely exposed to the air, the action was always more rapid than when it was stored in an air-tight case. This fact was well exemplified in a series of pictures—one half of each having been kept under the two conditions—shown by the late Mr. J. R. Sawyer, in illustration of a paper he read before the Photographic Society some fifteen years ago. A couple of years or so after this, Mr. E. W. Foxlee, in a paper he read before the then South London Photographic Society, demonstrated that the continuating action was entirely dependent upon moisture, and, if that were absent, it was completely arrested. By thoroughly drying the tissue after exposure, and then sealing it up in an air-tight case, prints were kept for six

months which, when developed, proved to be no darker than corresponding ones that were developed immediately they were taken from the frames. Heat also, in conjunction with moisture, was shown to be a considerable factor in the case, as it greatly accelerates the action.

If a carbon print be given, say, one-fourth the normal exposure, and is then kept in a damp atmosphere, at a temperature of about 80° Fahr, for an hour or so, it will, on development, prove to be quite as dark, and equally as good, as one that has been fully exposed in the first instance; whereas, had it, instead of being made damp, been dried and kept dry, it would have gained nothing with even many months' keeping. This shows, in addition to what was said in the previous article, what an important point is hygroscopic condition in carbon printing.

Let us now consider how this particular element, in reference to the continuating action, applies in every-day practice. Suppose the tissue is obtained ready-sensitised, and in the proper state for use. If it happens, however, to be printed in a frame the pads of which are slightly damp, moisture will be absorbed from them. Therefore the print, if kept for a few hours, particularly if the temperature is warm, it will turn out over-printed, while another print, produced under precisely the same conditions, so far as exposure and time of keeping are concerned, but with perfectly dry pads, will be exactly right. Again, supposing the prints, when taken from the frames, are exposed for long to the atmosphere of the work-room, and that is humid, as is generally the case where the development is conducted, the darkening action will progress rapidly, and they will prove over-printed, and thus necessitate a prolonged development. Want of attention to, or lack of knowledge of, these matters fully accounts for many of what have been termed the "uncertainties" and "vagaries" of carbon printing, and much retarded its practice, when a few years ago it was surmised by some that it would entirely supersede silver printing. It has just been mentioned that the continuating action was for a long time denied on the Continent. This may, however, be accounted for by the fact that there the air is usually much dryer than it is here. Hence the conditions pertaining were widely different.

Where carbon printing is conducted on a large scale, considerable advantage is taken of the continuating action during the dull winter months. The pictures are partly printed, and then kept in the dark until they become deep enough. But much more might be done in this direction than is, we believe, the case at present, inasmuch as the partially printed pictures are only kept under normal conditions as to temperature and humidity. The experiments referred to above show that, by increasing the moisture and at the same time the temperature, the effect that would otherwise take one or two days to obtain can be secured in the same number of hours. Yet, so far as we are aware, this system of quickly curtailing the exposure is not adopted commercially, though we do not know why. Perhaps, however, there are practical difficulties in the way.

As moisture, coupled with temperature, are such important elements in the carbon process, it would seem advisable to always keep a wet and dry-bulb thermometer suspended in the work-rooms. If this were done, it could be seen at a glance the hygroscopic condition of the atmosphere, as well as its temperature. Such a thing would often prove of assistance to inexperienced workers.

The Large Sun Spot.—Among other photographic achievements is a sun-spot photograph, taken between February 8th and 18th; for it beats the record, being the largest spot photograph since the observatory began the series in 1873. The spot is nearly a hundred thousand miles across, and it is anticipated that it will again come into view after being carried by the sun's rotation round his farther side.

The New Star.—Most of the newspapers of the day have given us articles of more or less value upon the new star lately discovered in the constellation Auriga, and photos, spectroscopic and otherwise, have been produced by various observers. Father Denza, at the Vatican Observatory, adopted the plan of slightly moving the telescope in declination between each exposure, and thus obtained five images on each of the two negatives he obtained.

Photographing Medals and Coins.—We might, in connexion with this subject, refer to the photographing of medals and coins. Those who have attempted it are aware of the great difficulty there is, even with perfectly new subjects, in avoiding the appearance in the negative of numbers of fine scratches, though they be almost invisible upon the coin itself. The effect is produced by the unequal reflection of light being reproduced by the photograph, while to the eye the flood of light drowns them. To make the most successful negatives, the method adopted by those who make a business of this kind of work is to make a plaster of Paris reproduction, and take the negative from it instead of the original. Every detail is reproduced, and all irregularities of surface vanish.

Modification of the Platinotype Process.—At the Camera Club Conference, on Tuesday last, Mr. W. Willis read a paper on *Some Recent Improvements in Platinotype*, in which he announced that he had succeeded in producing a paper which allowed of development at ordinary temperatures. Beyond the fact that the platinum is in the paper in this modification, and that the ordinary oxalate bath is employed as usual, Mr. Willis did not, and, of course, naturally, give any details as to the means chosen for achieving the result. He, however, claims for the new paper that it gives pictures finer in grain and line than the old hot-bath paper, and, from the appearance of the specimens which he developed at the meeting, the claim seems well founded. The subject excited considerable interest among those present. For further details we refer our readers to our report of the Conference.

Gold and Silver in Sea Water.—It has long been known that silver and gold are constantly to be found in sea water. Lately, paragraphs have appeared in the press relating to such presence of gold (and other metals), and referring to a patented electrolytic process for obtaining the metals. Mr. Sonstadt, whose paper on the subject, published many years ago, and which is presumably referred to, writes to the *Chemical News* to say that he never said that he found a grain of gold per ton, and that what he did say was that there was less than a grain. He now damps the ardour of would-be "residue savers" by saying that the quantity is very much less than a grain, and is so small that, though he can prove its presence, he has not been able to estimate his quantity. We are afraid that nitrate of silver and chloride of gold will not be cheapened by the produce of the sea, though, at the rate the former metal is coming down in price—viz. 5½*d.* having been a common quotation for some time past—we may expect a material reduction in price in many sensitised media.

Photographing Small Solid Objects.—The best method of photographing a series of small solid objects arranged in certain order is not very familiar, and an article on the subject appears in *La Nature* last week, which may seasonably be brought before our readers' notice. The plan consists in placing the objects upon a table or other flat surface, and then photographing them either by means of a camera placed vertically or else horizontally, with the lens supplied by a reversing prism, or, which would be cheaper, a reversing mirror. The latter method involves an amount of expenditure which

in many cases the photographer would not care to undertake, but *La Nature* pictures a simple apparatus that would not be costly, and would be useful for many purposes. The camera rests on a support carried by two uprights of plain deal, which are attached to the sides of a plain table, the top of which is made of a sheet of glass. The objects are placed upon this glass and light reflected from below, to form a suitable background, from a board covered with white paper, and placed at an angle so that any depth of light can be given by varying its position, or the white paper may be replaced by a suitable grey. This is an important part of the arrangement, for it sometimes happens that the whole success of the negative depends upon the background being of suitable depth. Without the glass a complete re-arrangement of the objects would be necessary if it were found that a colour chosen were too dark or too light. It is, further, obvious that it would not suffice to place the coloured paper immediately below the glass, as then the objects would throw shadows which might interfere with their outlines, although to a certain extent this might be obviated by the use of "ground glass." Objects of spherical shape which might give trouble by rolling are kept *in situ* by means of a spot of yellow wax.

Light-Sensitiveness of Phosphorus. — It has long been known that phosphorus, in some of its modifications, is sensitive to light; but in an article recently published in *Nature*, over the signature of A. E. Tutton, we find an amount of sensitiveness described that is rather unexpected. Phosphorous oxide, in the white, wax-like solid form in which it usually condenses after distillation, is, he states, remarkably sensitive to light. Thus, "ten minutes' exposure to bright sunshine suffices to turn it bright red, and after half an hour it is rendered dark red." The red matter that gives the colouration he finds to be the well-known red modification of phosphorus, but even after several months' exposure it does not exceed one per cent. of the weight of the oxide. The beautiful isolated crystals obtained by sublimation *in vacuo* appear to be unaffected by light; but it is a curious fact that if one of them be melted by the warmth of the hand, and the liquid globule afterwards suddenly cooled to the wax-like form, the latter becomes red, as in the former instance. There are not yet sufficient data to enable the chemical changes undergone in this experiment to be predicated. The phosphorous oxide thus experimented with has not been at all fully dealt with in the text-books on the subject. Mr. Tutton states that it is quite a mistake to suppose that, when phosphorus is burnt in a combustion tube in a slow current of air, the lower oxide, and not phosphorous pentoxide, is produced. Scarcely a trace of phosphorous oxide is obtained under these circumstances, the white amorphous powder deposited being pentoxide. It is only when the current is at all rapid that phosphorous oxide commences to be formed. Full particulars are given as to the mode of production in the article we are referring to. Those of our readers who would care to follow up this most interesting subject we refer to *Nature* for March 10 last, pages 44 *et seq.*

RATIO OF GRADATION.—II.*

So far I have attempted to show that, even accepting Messrs. Hurter & Driffield's results and deductions, they do not greatly interfere with the preconceived notions and daily experience of photographers. We are accustomed to talk a great deal about latitude of exposure and development, but in ordinary every-day practice these are not greatly strained, certainly not beyond the bounds which the experiments of these gentlemen allowed for. We may, by variation in development, make very thin or very dense negatives from similar exposures, but it does not follow, nor does it appear likely from a careful consideration of all the circumstances, that the ratio between those gradations is in any way altered.

But now it remains to be considered whether or not it is possible, by *any* modification of development, to control or alter the gradations; I mean, of course, by resorting to abnormal variations, or very wide departures from the regular practice. I am inclined to argue that it is possible, though even there I am placed in a difficulty, in not being fully acquainted with the details of the original paper. For instance, looking at the effects of reversal of the image, or the production of a negative from a negative by a prolonged exposure, will there be no alteration in the ratios of gradation of two images, formed by extremely extended exposures, and developed by widely different solutions? Again, is it not possible, by the use of excessive quantities of restraining bromide, by the addition of gallic acid, bichromate of potash, or a dyad bromide, as suggested by Mr. Phillips, to so alter the gradation? I certainly think so.

But we must keep in view the fact that Messrs. Hurter & Driffield deal mainly, if not wholly, with the change of density of gradations produced by one developer, while the practical photographer concerns himself rather with producing, by means of one solution, additional gradations that another solution is incapable of rendering, or with suppressing some of the superfluous energy of a developer too powerful for a given exposure. Messrs. Hurter & Driffield may say, and possibly they are correct, that, while it is perfectly possible for the practical man to do this, the gradations which remain within the common reach of both solutions—which are, in fact, neither added nor suppressed—still remain in the same ratio to one another. It may be so, but, in the light of one or two experiments I will detail, it does not seem so to me.

The accurate measurements of the relative densities of different portions of a half-tone negative, whether portrait or landscape, is far from an easy matter to an ordinary photographer without special apparatus, but any one with the aid of a graduated scale can arrive at a tolerably approximate comparison of the results produced by different forms of development. The scale I have constructed for the purpose of this trial consists of twelve tints, formed of varying thicknesses of the fine paraffined paper sold for wrapping purposes. The range of tints is beyond what any one plate and developer will reproduce satisfactorily; that is to say, if one end of the scale is perfectly rendered, two or three, or perhaps more, of the tints at the opposite end will be either not rendered at all, or will present one even density. I have purposely arranged that this shall be so, in order to allow full scope for the developer in either direction while I work with the central portion of the scale as representing the correct gradation obtainable under ordinary or normal conditions.* It may be as well to observe that I do not claim, either for the scale or for my method of procedure, any pretensions whatever to scientific or mathematical accuracy; they are simply arranged for the purpose of somewhat roughly illustrating my argument.

At the outset I ascertained, by means of several exposures, the conditions under which, employing a certain developer—which for my purposes may be called the standard—the central portion of the scale could be rendered in correct gradation, or, at least, as representing a series of varying tints, clearly distinguishable one from the other. These were found to be, using a rather slow film, an exposure of ten seconds, at a distance of three feet from a paraffin lamp, the developer employed being a "one-solution" of para-amidophenol hydrochlorate, with sodium carbonate. Under these circumstances, which I call normal, the result was that the first three tints were practically undistinguishable, but from that point up to the eighth, inclusive, the gradation proceeded regularly. The ninth tint was barely visible, but so faintly as not to be worth consideration. The effective scale, therefore, consisted of six tints.

Next, a series of extended exposures was made, to try the possibility of securing a normal result from over-exposure and modified development. The most marked effect was obtained with an exposure of seventy seconds, others varying only in degree. With the strip of film developed with the normal developer, only the four highest tints showed any appreciable difference, from one to nine taking a uniform

* Since this was written, I have received, through the kindness of Mr. Alexander Cowan, a copy of Messrs. Hurter & Driffield's original communication, from which I find that they have, in their experiments, varied the conditions of development, both as regards time and composition of solution, to a far greater extent than I had supposed, though still within the bounds of what may be considered ordinary development. My intention in this article was not to question the accuracy of their deductions from one of the most ably conducted and elaborate series of experiments ever carried out in connexion with photography, but rather to open new ground, which, from a hasty perusal of their paper, I think I have done, though in an imperfect manner.—W. B. B.

* The scale was constructed the full width of a quarter-plate, so that a single plate could be cut up into strips for treatment with different developers, or could be exposed in successive strips for varying times, if it should be desired to try the effect of different exposures under the same development. The tints are numbered from the lowest or most transparent on the scale.

density, ten, eleven, and twelve showing comparatively little difference one from another, the whole four tints, in fact, being very weak. The other strip was developed with alkaline pyro, the solution containing the ordinary proportion of pyro, a large proportion of bromide, and a minimum of ammonia, the exact proportions of each being, to the ounce, three grains of pyro (with twelve grains of sodium sulphite), five grains of potassium bromide, and half a minim of strong ammonia. With this feeble action, and at the same time well-restrained solution, the development was continued until the twelfth tint was barely visible, the whole image being then so feeble that there appeared to be no gradation at all. Meanwhile, standing ready in a minim measure, was a concentrated solution, which, when added to the developer, brought its strength up to twelve grains of bromide and a minim and a half of ammonia to the ounce, the pyro remaining the same. Under the action of this more energetic solution, the lower tints rapidly began to gain density, and the application was continued until the gradation of the highest tints was discernible by reflected light. Upon fixing and examining carefully, the separate tints were clearly distinguishable as far down the scale as number five, after which the remainder assumed the same density, although at times, and in certain lights, it seemed possible to detect a difference between four and five. I will, however, be satisfied with claiming eight distinguishable tints, or an improvement of four over the normal development of the corresponding slip.

Now, it will be noted that this result gives two more tints than were obtained with the normal exposure, which resulted in six only; but the interval covered by the latter—in other words the "contrast"—was considerably greater than in the case of the over-exposures. Comparing the two over-exposed slips, the density or opacity of the lower tints of the restrained development was notably greater than in the densest portions of the other image, and at the same time the highest tints were decidedly more transparent. In fact, the increased number of tints was accompanied by considerably augmented contrast, although in this latter respect the result was inferior to the normal plate.

W. B. Bolton.

A NEW DRY-PLATE FACTORY.

Pleasantly situated on the outskirts of Cricklewood, and facing the pretty open country of Dollis Hill and Edgware—a district which is as yet hardly disfigured by modern building operations—are the new premises of the Imperial Dry-plate Company. For the purpose to which these premises are to be devoted, the situation could not be more desirable. The erection itself is a neat structure, in harmony with its surroundings, and should the meadows in its vicinity be one day covered, as seems possible, with villa residences, the inhabitants will have no cause to complain of that unsightliness or other drawbacks usually associated with manufacturing premises.

If the process of making dry plates, as generally employed nowadays, presents few of the terrors and uncertainties of which the makers of ten or a dozen years ago stood in constant dread, the necessities of competition demand that facilities for their preparation should be of the completest and, indeed, of the most scientific nature, since it is chiefly upon the perfection of the mechanical arrangements involved that commercial success can, in these times, be hoped for. In these respects we believe that the Imperial Company will be at no disadvantage whatsoever, especially when taking into consideration the fact that the guiding spirit of the enterprise, and the one upon whom the direction of the fitting up and equipment of the new factory has devolved, is Dr. J. J. Acworth, in whom many of our readers will recognise an old contributor to these pages, while others within a smaller circle know him to be experienced in both the theory and practice of gelatine emulsion-making, as well as a chemist and physicist of considerable attainment.

On the occasion of a recent visit to the Imperial Company's works, we were shown, under the guidance of Dr. Acworth, the principal parts of the premises set aside for the preparation of the plates. Commencing with the glass-cleaning room, we observed that the glass is cleaned by immersion in hot water. It is then, after draining, passed on to a drying room, the temperature of which is uniformly maintained at 85°. When it is dry it is placed in boxes, and is sent up by means of a lift to the coating room. Here we witnessed the coating of several dozens of 9½ × 6½ plates by means of a Cadett's coating machine. So soon as the plates receive the emulsion they are slowly carried, over water and under glass, to an employé who receives them at the end of the machine which is several feet long. When they reach his hands the emulsion is set. After the plates have been examined against the non-actinic light for evenness of coating, they are stacked in wooden racks, and are then ready for drying.

The operation of drying is conducted under conditions differing from those which we have generally seen employed for the purpose. Instead of a specially provided drying room, having the requisite rack accommodation, drying chambers are used. These are just so many long, narrow cupboards, capable of being closed in. The racks holding the plates are placed in them, and by a simple mechanical arrangement movable from the outside, the racks may be passed through from one end of the chamber to the other. The chambers are, of course, maintained at a uniform temperature, and their great advantage is, that, in contradistinction to ordinary drying rooms, no one has access to them, and thus the dissemination of particles of dust is minimised, if not practically avoided altogether. At the end of the drying chambers the plates are received for examination and packing, the arrangements for which were shown to us.

We did not witness any of the actual operations connected with the preparation of the emulsion, but we were shown the rooms in which the finished emulsion was cooked, this being conducted in steaming boilers. We also saw the room devoted to the washing of the emulsion, the arrangements for which are on a workmanlike scale. In the coating and other dark rooms the light employed is a very agreeable variety of orange, by no means trying to the eyes. In addition to the departments described, the premises include a carpenter's shop, and, of course, an engine and boiler-house. The engine is a three horse-power, by Hindley, and, looking at the amount of work it does in driving and heating, we must regard it as a very valuable member of the staff. A considerable section of the factory is devoted to the sensitising of albumen paper.

Dr. Acworth tests his plates in the camera, and, in addition to a laboratory devoted to the general purposes of the plate-making, has provided himself with a handsome and well-appointed private laboratory for experimental purposes, in which he hopes to carry out a great deal of photo-chemical research and investigation. The task of superintending and setting the factory in working order has fallen entirely upon his shoulders, and, if the success of the Imperial plates may be foretold from the arrangements entered into for their manufacture, a happy issue should await the venture. We gather that emulsion-paper coating will be undertaken at a future date, for which, as well as for other purposes, considerable spare space is available.

CAMERA CLUB CONFERENCE.

The Conference week of the Camera Club opened on Monday last with the annual exhibition of members' work, which was on view at the Club Rooms. The exhibition is of a non-competitive character, while we believe that the pictures are not required to pass the ordeal of a committee of selection. These facts, to our thinking, afford the best scope for gauging the collective skill and merit of the general body of the Club's members, which, in the present case, we are happy to pronounce as high. The Camera Club has the advantage of numbering among its members many of the foremost photographers of the day, of whose works an excellent selection is shown. Messrs. P. P. Cembrano, H. P. Robinson, J. Gale, and Henry Stevens are represented by some of their most familiar and characteristic pictures; Mr. A. H. Dresser by some clever seascapes taken with a hand camera, and Mr. Gambier Bolton by a small but happy series of animal studies. Mr. H. M. Hastings' interiors are sound in technique, and we were pleased with the thoughtful landscape work of Messrs. Guardia, H. E. Davis, Darcis, and others. The portrait studies are few, and some of them betray high artistic treatment. Of course, at a Camera Club exhibition, one expects to meet with examples of the newest style of focussing, and at that now under notice there is no room for disappointment. In the unnamed collection of frames, which our acquaintance with the peculiarities of his work warrants us in attributing to Mr. George Davison, there is material for considerable controversy on this point, although it would be impossible to deny his keen artistic instinct. On the whole, the exhibition, which is to remain open for several weeks, will more than repay inspection, although it may not be completely convincing to thick-and-thin admirers of the "old school" pure and simple.

THE PRESIDENT'S ADDRESS.

The theatre of the Society of Arts was well filled when Captain Abney rose to deliver his opening address. In this, after referring to the Brussels Congress which was held last year, he said that the report of Mr Warnerke and himself, the English delegates on that occasion, was only

ust out, so that it was difficult to tell to what extent the standards agreed on would be adopted in this country where the inch and the grain were deeply implanted. Despite M. Lippmann's experiments of last year, photography in colours had not made much advance, and his opinion was that in the present state of our knowledge the problem would only be solved in the very remote future. Lippmann's colours were permanent, but they were dependent on the length of exposure and not on coloured light. He (Captain Abney) had obtained different colours that way himself, but they were not pure spectrum colours. The results obtained militated against the reproduction of absolute colours such as were found in nature. The reason for this was simple. The colours might appear to the eye the same as fine spectrum colours, but such colours mixed would also give a percentage of white light. Mr. H. M. Elder had recently investigated the colouration of silver chloride by light, and had advanced a photo-dynamic theory of the change, and he and every one who had heard the paper had come to the conclusion that it was an excellent type of paper. It threw much light on the action which occurred, and had not received the attention it deserved from the chemical point of view. Mr. C. V. Boys had lately produced photographs of bullets in motion by the spark of the Leyden jar. Mr. Boys was a typical experimenter. After referring to recent discoveries in astronomical science by the aid of photography which proved that star magnitudes determined by the eye and photography agreed, the President touched upon the luminosity of feeble lights of various colours, and concluded his address by endorsing the movement in favour of the establishment of a photographic institute, and said it was as necessary as many kindred institutions. They must start in a modest way, not aiming too high at once, in a modest building, with a modest equipment and modest instructors.

CHEMIGRAPHIC ETCHING.

Mr. Leon Warnerke gave a demonstration of chemigraphic etching, remarking that the subject was not new. He said that photo-engraving processes were not so extensively practised in this country as they might be. The principle of zinc plate etching had been demonstrated by himself before more than once, by Mergert thirty years ago, and by Gaudin in 1873. Certain metallic salts were precipitated on a sheet of zinc, and a weak acid solution, which would not attack the zinc, was then applied, which acted where the precipitate was formed with evolution of hydrogen. The state of dilution of the acid solution was determined by the particular metal precipitated—with cobalt, a strength of 1:10,000 being sufficient; with other metals the solution could be stronger. The most powerful precipitant was nickel ammonium tartrate. Alkaline salts acted more powerfully than acid salts. The depth of the etching varied with different salts employed, nickel giving deepest results, and lead allowing the etching action to proceed very faintly, while with mercury the acid solution produced no change. He did not deem it necessary to enter into photographic details, as they were familiar to all; but before giving the demonstration, he would say that aluminium promised very well for etching purposes. It was a capricious metal, being insoluble in nitric and sulphuric acids, and easily soluble in hydrochloric acid or caustic potash. Nitric acid has no action on the bare aluminium, but if this were covered with a precipitated metal, the nitric acid acted on it very powerfully. This was the case where mercury chloride was used. Mercury chloride appeared to produce an amalgam.

Mr. S. B. Webber asked if the aluminium should be used rolled or soft.

Mr. T. R. Dallmeyer asked if Mr. Warnerke had experience of working on the surface of aluminium. In processes of photo-engraving, a considerable amount of work had to be done after the chemical action was stopped, which was left to the photographers. Pure aluminium was difficult to work.

Mr. H. M. Elder said Mr. Warnerke, in mentioning the action of mercury chloride on aluminium, had placed a new power in the hands of photographers. As to what the theory of the action might be of oxygen and acids on aluminium, he had always imagined that it had a thin protective film on its surface. A recent paper on the action of acids on zinc pointed out that the probable cause of the absence of action of dilute sulphuric acid was due to a surface of hydrogen formed on its surface. Such action was 700 times greater where the solution was contaminated with chromic acid.

Mr. Warnerke, in reply to the various questions, said, as regards etching, similar results were obtained with hard as with soft metal. As to working on aluminium, it was different to other metals. In cleaning for photo-engraving purposes, the process was much the same. For turning it did not behave very well, but turpentine, or any mineral oil, greatly facilitated working. There was no difficulty in using the graver.

RECENT IMPROVEMENTS IN PLATINOTYPE—A NEW COLD-BATH PAPER.

Mr. W. Willis read a paper, in the course of which, after pointing out that the effects of lowering the temperature of the developing solution in the hot-bath process reduced the chances of successful development, brought out defects in the paper, and gave a granular deposit of the image, he said that, in 1888, he had attempted to make a paper developable at ordinary temperatures. The cold-bath process, since brought out, had, however, been disappointing, and the hot-bath process had been found more generally useful. They could now develop at much lower temperatures than formerly, 90° being the limit reached. But failures often occurred, due to the low temperature, as rapidity of reduction varied with the different temperatures. He had recently discovered a method of preparing ordinary platinum paper so that rapidity of solution should not overtake that of reduction, and the image developed before the salts could be removed from the paper. For obvious reasons he could not make the process public, but development conducted at a temperature of from 50° to 70°—normal temperature—gave results equal to those obtained at 130°, free from granularity and other defects. The process had only recently been perfected, but it was completely under control. It might not please his friends of the new school, who did not want fineness of deposit; but more photographs depended for their value on the very quality which the modern school rejected. He showed a number of graduated comparisons between the new paper and the old at various temperatures, the former being much superior in fineness of detail and clearness of line. The ordinary paper was developed at 130°, and the new at 56°. With the latter the ordinary oxalate bath or that containing ortho-phosphate could be used. Development of the new paper was slower than the old, thirty seconds being required before the action was complete. The addition of a small quantity of hypophosphite of sodium gave control of development. Mr. Willis then developed several pictures at a temperature of 64° Fahr. These were much admired. Development in sections failed to produce lines in the pictures.

Mr. Francis Cobb asked whether it was necessary to have three acid baths, as with the old process, and how long it was safe to work the oxalate bath.

The Rev. F. C. Lambert inquired if the improvement was applicable to sepia paper.

Mr. R. Keene presumed the paper required the same careful storage from air and moisture. Could the oxalate be kept up by adding to it?

Mr. J. Gale asked if rough-surface paper could be used with the process.

Mr. Tate asked when the new paper would be on the market, and its price.

Mr. R. W. Robinson inquired if it were possible to get warmer blacks, and if time of exposure had any effect.

Mr. Willis, in reply, said three acid baths were necessary. The oxalate bath could probably be used as long as with other processes, and the new paper should be looked upon as the same as the old. His experience had been very short, so that he could say very little about it. Over-exposure could be controlled by the use of hypophosphite, or a little ice in the water. With under-exposure the developer could be warmed. He could not say whether the process was applicable to sepia paper, as it was a difficult problem to dissolve. He gave an affirmative answer to Mr. Keene's questions. The process might be used with rough-surface paper. There was no difference in the colour produced by under or over-exposure, although blue-black was exceedingly easy to obtain. Immersing the paper in water before development gave a warm tint—almost like sepia.

PHOTOGRAPHY APPLIED TO MEDICAL RESEARCH.

Mr. Andrew Pringle prefaced his subject by alluding to Professor Meldola's recent lecture, in the course of which he pointed out the special branches of science to which photography rendered notable services. He (Mr. Pringle) thought the Professor should have given more prominence to the services rendered by photography to medical research. To no special line of research had photography rendered such notable service as to medical research and treatment. During the last two or three years many new installations had been started in the medical schools for the purpose of recording the causes and appearances of diseases by the invaluable and trustworthy means of photography. It was important to have photographs of patients in disease before and after treatment, and photography was useful in cases where sketches could not be made, as, for instance, in a disease of the tongue. The flashlight was very useful in the hospital wards, results being obtained with it that could not be had by the ordinary means. In photo-micrography there was an idea that it was necessary to have expensive lenses. He showed a slide of a blowfly's tongue taken with one of Mr. Crouch's student lenses from a two-thirds object glass. The photo-micrograph was as good as any done with much more expensive instruments. Slides could be coloured to the natural tint by M. Lumiere's formula, which he (Mr. Pringle) had experimented with and published. For students, photo-micrographs of unique specimens were of great value, especially as they were now able to show slides on the screen of the same colour as the students saw them in the microscope. Incidentally he mentioned that the carbon process for this purpose was inferior to gelatino-bromide plates. Mr. Pringle's discourse was interspersed by a great many photo-micrographic slides bearing on its various points, at the conclusion of which he claimed that in photography medical science had a most useful adjutant. He thought they should do all they could to assist the medical profession by means of the science of which some of them made a profession and others a hobby.

At the evening meeting, Mr. Van der Weyde described his earliest attempts at applying electric lighting to portraiture and the development of his own methods, and concluded by taking portraits of Captain Abney and Sir George Prescott, using the apparatus at the meeting which had been roughly set up for the purpose; and Mr. E. J. Humphery exhibited the working of a globe lamp for portraiture, also the lamp adapted for printing purposes (platinum and silver), in which magnesium powder, hydrogen and oxygen under pressure, was employed as before. It had, however, been improved, so as to *print in four or five seconds*, actual platinum prints being made and developed by the "new" cold developed paper.

Mr. H. E. Armstrong then read a paper on the *Theory of Development*, the discussion on which, on the suggestion of the President, was adjourned until a future meeting of the Camera Club, inasmuch as the paper contained matter which required consideration.

WEDNESDAY'S PROCEEDINGS.

At the meeting on Wednesday afternoon Mr. J. B. Spurge exhibited his safety gauge, and said that, in order to render safe from explosion the gauges that are employed for indicating the pressure of gas contained in the cylinders employed with the lantern, he would exhibit Clarkson and Spurge's improvements for that purpose. Their improvement consisted, he said, in filling the interior with a fluid that is practically incompressible, thus preventing access of gas to the gauge; consequently there is nothing allowed within that can possibly explode, and danger from that source is entirely avoided.

He also described some improvements on his sensitometer, in the direction of constant times of exposure, and concluded by exhibiting results tending to show that, in opposition to Messrs. Hurter & Driffield's theory, negative gradations could be changed.

A PAPER ON PARADOXES.

The paper on *Paradoxes of Art, Science, and Photography*, by Mr H. P. Robinson, was read by Mr. George Davison, the Hon. Secretary. In it the author, on his own admission, tried to make the paper as intangible and contradictory as art itself, an object in which he succeeded most admirably, as will be seen from the paper, which we give in another part of the JOURNAL.

Mr. J. Pennell said Mr. Robinson's lies were extremely amusing. He told lies without knowing it, although he did not mean to. The biggest lie of all was when he said impressionists had produced nothing worth seeing. Velasquez, Raphael, Titian, and, in fact, all great men were impressionists. Their impressionism was their way of looking at things. Art was intimately connected with science, because artists went about their work in a scientific way, although they hid the fact.

Mr. A. Maskell said no doubt Mr. Robinson's paper would alarm his admirers. He was hardly serious, although he had given them a series of delightful paradoxes delightfully expressed. He hoped his own pictures on the Camera Club walls were not the least untruthful there.

Mr. E. J. Humphery thought that some day they might come to regard Muybridge's pictures as both artistic and truthful. The truth was what appeared to be truth at the time.

Mr. P. H. Newman said Mr. Robinson had himself demonstrated what truth was. Art had to do with appearances, and not facts, and Mr. Robinson had been dealing with appearances that afternoon.

The President objected to the term "scientist," which he hated, and he considered Mr. Robinson had prostituted the English language in using the term. He (the President) would rather be called a tomfool than a scientist. He had no pretension to art, but as Mr. Robinson had had his fling at science, he (the President) thought a response was demanded of him. Mr. Robinson had not treated science with respect. What was truth? Truth in art was something totally different to truth in science. As a scientific man, he was bound to say that, if you analysed the works of artists, it was wonderful how scientifically incorrect they were. Perspective had improved, owing to photography. Artists had painted moonlight pictures of mountains hundreds of miles high. That was not truth, and science proved the falsity. Photography was invented by science, and art would not have had any truthful characteristics but for science. When painters wanted information about their pigments, to whom did they go? Not to artists, but to scientific men. Artists could not do without science, and never would. The longer they lived, the more highly civilised would they become, and the more art would depend on science, and the more artists would have to paint according to the dictates of science.

USES OF PHOTOGRAPHY TO THE DECORATIVE ARTIST.

Mr. H. H. Stannus next delivered a discourse, in which he pointed out the various applications of photography to decorative purposes. With reference to the hanging of photographs, he saw no objection to their being hung with oil paintings, rather the reverse. They should be hung at the level of the eye. With pictures and photographs hung together, the colours mutually helped each other. He objected to classification, and preferred small pictures under large ones, in the style sometimes adopted with paintings. The charm of photographs was their quietness of tone. For filling up windows photography offered an admirable field, but he did not think it could yet compete with the brush of the artist or the productions of the colour. On textile fabrics the detail was lost, and the absence of a variety of colour was a drawback. Photography was, as they knew, of great use in draughtsmanship for enlarging or reducing. Adverting to the discussion as to what was truth, he said truth need not be ugly. Science was a matter of fact, and art of appearance. He regretted to hear untruthfulness defended by a photographer, and said that retouching should always be acknowledged. In archæology and architecture photography was of much service; and for travelling students the camera was a great help. He advised photographers to take their architectural views to scale by putting a two-foot rule on some part of the picture, and also always to carefully note the aspects of buildings for future reference, and concluded by recommending the establishment of a record office with photography to supply the material.

Mr. Robinson said that in his paper he had referred to picture-making, in which they did not want facts. He objected to two-foot rules in his pictures, which he only estimated from the point of view of their pictorial qualities.

Mr. Francis Cobb thought photography was not untruthful until high art had made it so. Mr. Stannus should go to the Astronomical Society and ascertain what was being done in the securing of a truthful record of the heavens—the most truthful thing yet accomplished.

Mr. P. H. Newman said artists were undoubtedly much indebted to photography, and agreed with Mr. Stannus in his suggested arrangement of photographs and oil paintings together. It was difficult to arrange photographs in a small room, as he had pointed out elsewhere, and he regarded Mr. Stannus' ideas on the subject as a valuable continuation of his own.

Mr. W. S. Bird said that it seemed to him that the difference between art and science was that one appealed to the emotions and the other to the intellect.

Mr. Maskell suggested the leading of transparencies as in stained glass windows, and also the application of large photographs to walls. He also thought that, in laying foundation stones, photo-micrographic records on china plaques would be practically indestructible. They could easily be enlarged by some future discoverer.

THE DEBT OF ART TO PHOTOGRAPHY.

Mr. Henry Blackburn was the next speaker, and he cheerfully acknowledged the services of photography in reproduction processes, and its uses in daily illustrated journalism. He thought that photographs of Carlyle still extant represented the man and the historian better than Millais', Watts', or Whistler's portraits. Artists did not like photography, although they employed it. He quoted instances where photographic enlargements had formed the bases of spurious oil paintings, and he placed this fact to the debit of photography. The subject of the Muybridge pictures had cropped up again that afternoon, and he would endeavour to settle it once for all. He and several friends once went out coursing, to compare notes as to the impression produced by a travelling hare, and they agreed that the appearance of the extended limbs of the hare during an isolated moment of time was a mere impression. The animal, as it were, floated—as they saw it. He appealed to Mr. J. Pennell, as an illustrator of books, to make his drawings more suitable for photographic reproduction.

Mr. J. Pennell said that it was not the fault of photography that his drawings were criticised, although he found that no Englishman could reproduce them so well as foreign firms. He complained of the paper which was used in the press.

Mr. H. G. M. Conybeare pointed out that, in viewing the movements of animals, the eye had a tendency to see what it wished to see.

Mr. P. H. Newman said that the faculty of perception which artists had was of advantage in considering the truth or otherwise of such pictures as Muybridge's.

Mr. T. R. Dallmeyer was of opinion that both artists and photographers, when producing distant objects, conveyed the sensuous impression, but that photography, when applied to near objects, failed to do so, and in this respect it was inferior to painting.

The Rev. F. C. Lambert pointed out the important part which heredity had in the impressions of objects produced on the mind.

The Conference concluded with the reading of a paper by Mr. C. H. Bothamley on *Some Points in Connexion with Development*, which briefly dealt with Messrs. Hurter & Driffield's theories, Mr. Bothamley's opinion being that those gentlemen had not proved their case.

The annual dinner of the Club was held on Wednesday evening at the Monico Hotel, over a hundred members being present. Captain Abney presided. Among the toasts were the Club, proposed by Mr. Henry Blackburn, and acknowledged by the Chairman; the Visitors, replied to by Mr. H. Van der Weyde; and the Photographic Press, acknowledged by Mr. J. Traill Taylor (THE BRITISH JOURNAL OF PHOTOGRAPHY), Mr. H. Sturmey (*Photography*), Mr. E. J. Wall (*Amateur Photographer*), Mr. W. Welford (*Photographic Review of Reviews*), and Mr. J. Hay Taylor (*Optical Lantern Journal*). Music and recitations enlivened the proceedings, which were kept up till a late hour.

THE POSITION OF STEREOSCOPIC PHOTOGRAPHY IN REGARD TO BEAUTY AND UTILITY.

[Glasgow Photographic Association.]

When asked to write a paper for this meeting, it struck me that I could not do better than introduce a discussion on a subject which occurred to me during the exhibition lately held in our city, and which has often been in my mind since, viz., to inquire into the reason for the great revival of stereoscopic work among the photographic fraternity.

There are several classes of men who photograph; and, setting aside those who employ photography as an agent in scientific research, I think they may be divided into three classes. There are those—chiefly professional—who photograph for monetary gain, and they do stereoscopic work because an eager public desire to buy stereoscopic photographs to entertain their friends in the drawing-room. This is business, and it were treason to criticise the great Mammon God of the Briton.

Then, there are those—mostly amateur—who photograph because they desire relief from the monotony or worry of their daily avocations, or because they have much leisure and require some hobby to occupy their time and thoughts, and they find in the manipulation of cameras, plates, papers, and solution, a satisfactory outlet for their energies. These hail stereoscopic work as a delightful variety, and naturally become enthusiastic over it. They re-photograph all their old views, and, as they show the results to admiring friends, they expatiate on the marvellous reality of the appearance, how everything stands out, and how, were the objects but coloured, the observer might imagine himself to be looking at the actual scene through a binocular. The admiring friend acquiesces, and remarks, "What a wonderful thing science is; do you think photographs ever will be be taken in colours?" This class photograph for the pleasure they derive from the manipulation. It is a harmless and interesting amusement, and they might readily be much worse employed.

Then, there is a third class of camera men, who photograph because of the results. Some like to have a picture record of the places they have visited to remind them of a happy holiday, and to illustrate their public or private lecture to less fortunate brethren who stayed at home; and there are some who use the camera because through it they can acquire lasting impressions of much that is beautiful. Their albums contain notes of nature in all her moods; a wave, a cloud, the outline of a hill or tree-branch fixed by the camera is ever a pleasure to them to look at. They may or may not enjoy the manipulation, but the real end of their work is the album, not the dark room. Their object I consider the noblest, and it is from their standpoint that I wish to examine stereoscopic photographs to-night.

In the first place, I submit that it is impossible to appreciate the artistic qualities of a photograph, be it ever so fine, through any mechanical contrivance. Imagine an artist painting a picture of a view which he looked at through a telescope! To enjoy a work of art, the mind must be untrammelled by anything outside of it. To me this is the initial objection to the stereoscope. The disturbance created by the necessary fixing of the parts, getting a proper light, adjusting the focus, &c., is a source of irritation which effectually prevents the calm enjoyment of the beauty of the picture. In the second place, I submit that, after going through the trouble of fixing the instrument, the result is not beautiful. It may be interesting to see once, but it is not beautiful, and that for various reasons. I shall probably be told that the parts stand out and take their proper position in the plan of the landscape, that it looks natural and real, and that it must, therefore, be more beautiful than a flat surface could possibly be. With this I entirely disagree. That the parts stand out, I admit; that they appear real, to have solidity, I deny. Of course, I can only speak of the results as they appear to me; and, as I can see no reason why they should appear different to others, I take it for granted that what we severally see in looking into the instrument is approximately the same impression. Instead of having the appearance of natural objects with bulk or solidity, stereoscopic pictures always remind me of stage scenery painted on flat surfaces and set behind each other at short intervals. The reason for this impression is obvious. In nature it is impossible to see objects near at hand and objects at a distance in focus at the same time. In the stereoscope, however, the several planes are all seen in focus at once, and thus the effect aimed at by one means is directly annulled by another, with the result, as I have stated, that the various planes seem flat portions, separated only by a little space from each other.

At a casual glance, one is apt to think that it is necessary to alter the focus of the eye to see different objects in the stereoscopic picture, but more careful observation will show that this is not the case. The mind can only concentrate itself on one object at a time; but, if an endeavour is made to look at a near and distant object together, it will be found quite possible to do so. From a scientific point of view, it is obvious that, as the photographs are flat surfaces, the focus of the eye must be the same for all parts of the picture.

In judging an ordinary photograph, one of the chief points to be considered is, to what extent the feeling of atmosphere has been introduced into it. Painters devote their most earnest endeavours to convey the atmospheric impression in their pictures, for well they know that it is on the much-maligned atmosphere of our island that so much of its beauty depends. Now, the stereoscopic picture is absolutely devoid of all atmosphere, and must, therefore, be false and untrue to nature.

I have tried an experiment over and over again, and, as there is a stereoscope here, I would like you to try it also, and see whether you agree with me in the result. Look at a photograph in the instrument carefully, note all the glaring hardness, and the persistent manner in which every object seems to be calling out, "Look at me, I am standing out, I have no connexion with anything behind; you may have thought that I was on a flat surface, but look, you were mistaken; I have really no connexion with anything behind." Then, when you have noted all this, shut one eye, keep it closed, and you will find that it is really a very beautiful photograph at which you have been looking. The tree in the foreground has a lovely form, and the mass of stems behind blend into a delicious softness as they disappear behind each other in the distance.

The stereoscopic effect is an endeavour to imitate nature, while the object of an ordinary photograph or drawing is only to reproduce an impression of nature. The failure of the stereoscope in its greater aim is more marked than the less ambitious, but more practical, endeavour to reproduce on a flat surface an impression of what we see.

I contend, therefore, that stereoscopic photography, considered from the æsthetic standpoint, is a failure, that the stereoscope is only a scientific toy—and a false one at that—calculated to interest without either pleasing or satisfying. The truth of the axiom, "The boy is father of the man," is as clearly demonstrated in photographic matters as in any other department of life. When tops are "in," no schoolboy who has the slightest regard for propriety would dare to be seen with marbles in his possession, and six weeks later, when "tip-cat" is in vogue, tops have no interest for him whatever. In photographic circles at present stereoscopic work is "in," and I do not expect that anything I have said will affect the business of the maker of stereoscopic cameras and stereoscopes in the slightest degree.

As regards the utility of stereoscopic photography, I think that is confined to the instrument-makers and dealers in photographic material.

J. Craig Annan.

PARADOXES OF ART, SCIENCE, AND PHOTOGRAPHY.

[Camera Club Conference.]

"Stick to nature, my boy!" is an admonition often heard among artists, yet it is most true that, beyond a certain point, the closer the imitation is to nature the further it is from art.

Art is not so much a matter of fact as of impression; even realists admit this. Their objections to what is called impressionism is that the impressionists seldom say anything worth saying, and sometimes nothing at all, leaving a shrewd suspicion that they have nothing to say, and glory only in having no mission except to upset the experience and practice of centuries.

No possible amount of scientific truth will, in itself, make a picture. Something more is required. The truth that is wanted is artistic truth—quite a different thing. Artistic truth is a conventional representation that looks like truth when we have been educated up to accepting it as a substitute for truth. The North American Indian did not understand a portrait less than life size, or a profile with one eye only; he was not educated up to the convention.

Of late years there has been a great demand for truth in art, whatever that dark saying may mean. We have been impressed by the literalists to be faithful to nature. To quote Mr. Oscar Wylde, "They call upon Shakespeare—they always do—and quote that hackneyed passage about Art holding the mirror up to Nature, forgetting that this unfortunate aphorism is deliberately said by Hamlet in order to convince the bystanders of his absolute insanity on all art matters," reducing genius to the position of a looking-glass. On the other hand, it is sometimes said, perhaps jokingly—for we should not take Mr. Brett or Mr. Pennell too seriously—that photography cannot be art because it has no capacity for lying. Although the saying is wrong as regards our art, this is putting the semblance of a great truth in a coarse way. In other and more polite words, no method can be an adequate means to an artistic end that will not adapt itself to the will of the artist. The reason is this, if it can be reduced to reason. Admit that all art must be based on nature; but nature is

not art, and art, not being nature, cannot fail to be, more or less, conventional. This is one of those delightful contradictories that make the study of art an intellectual occupation. Men naturally turn to nature. We have evidence of this from prehistoric times. The ornament of all time, of all nations, with scarcely an exception, has been based on nature—the Greeks and Moors are the important exceptions—yet the ornament that approached nearest to exact imitation of nature has always been the most debased and worst. It is the lowest intellects that take the most delight in deceptive imitation. Mr. Lewis F. Day puts this very admirably in one of his recent publications:—"Those who profess to follow Nature," he says, "seem sometimes rather to be dragging her in the dust. There is a wider view of nature, which includes human nature, and that selective and idealising instinct which is natural to man. It is a long way from being yet proved that the naturalistic designer is more 'true to nature' than another. It is one thing to study nature, and another to pretend that studies are works of art. In no branch of design has it ever been held by the masters that nature was enough. It is only the very callous student who opens his mouth to swallow all nature, whole; the older bird knows better."

It is clear, then, that a method that will not admit of the modifications of the artist cannot be an art, and therefore is photography in a parlous state if we cannot prove that it is endowed with possibilities of untruth. But they who looking, perhaps, only at their own limited experiments, say photography cannot lie, take a very narrow view and greatly underrate the capabilities of the art. All arts have their limits, and I admit that the limits of photography are rather narrow; but, in good hands, it can be made to lie like a Trojan. However much truth may be desirable in the abstract, to the artist there is no merit in a process that cannot be made to say the thing that is not.

Here I am bound to admit a considerable weakness in my argument. We are told by a writer in a popular new magazine, edited by a member of our Club, that it is "always the best policy to tell the truth—unless, of course, you are an exceptionally good liar!" This is, indeed, a misfortune, for there is not, I am ashamed to say, very great scope for sparkling mendacity in our art. That is to say, we cannot produce brilliant falsifications, such as the painter may indulge in. One man may steal a horse, while another may not look over a hedge. A painter may unblushingly present us with an angel with wings that won't work, while a photographer is laughed at, very properly, if he gives us anything nearer an angelic form than that of a spook raised by a medium.

It must be confessed that it takes considerable skill to produce the best kind of lies. It is in the hands of first-class photographers only—and perhaps the indifferent ones—that photography can lie. With the first, possibly, graciously; with the latter, brutally. The photographers of only average attainments, and such as we should get turned out in quantities by an art-less Institute, seldom get beyond the plain, naked, uninteresting truth. Yet I think that many will agree with me that the very good and the very bad are much more interesting than the mediocre. That the best are interesting is clear; that the worst are often the cause of a good laugh is the experience of all; it is only the middling good that induce indifference.

There can be little doubt that, in this respect, and looking at it from this point of view, painting is a much greater art than photography; but what I am concerned to prove is that, although photography is only an humble liar, yet it is not the guileless innocent that some people suppose, and has a capacity for lying sufficient to enable it to worthily enrol its name among the noble arts. Nay, is it not the greater for its humility? Photography gives us the means of a nearer imitation of nature than any other art, yet has sufficient elasticity to show the directing mind, and therefore is the most perfect art of all. If we must have paradoxes, let us carry them to the bitter end.

"Let us have truth," says the conscientious writer who knows not what truth is. What should we get in art if we could capture it? We should have a representation of nature as we see it in a mirror, colours and all, and should tire of it as soon as the novelty wore off. The worst thing that could happen to photography as an art would be the discovery of a process giving the colours of nature—the one impossible thing in nature, I hope and believe. Its one great deviation from faultless virtue is, as I have endeavour to show, that it is more truthful than painting.

A writer innocent of the resources of the art, and wishing to depreciate it, make a point of the photographer having no control over the action of the developer so as to produce the variation from nature he desires. I can only reply that among my own pictures there is scarcely one that does not owe a good deal of any merit it may have to control of the developer. The possibilities of control were greater, perhaps, in the collodion process than the gelatine, but we are speaking of the capabilities of photography, not of any particular process. The scientist may prove, beyond any possibility of doubt, that the relative values cannot be altered in development, but the photographer knows that variation in development varies the appearance of his results, and that should be quite enough for him. It is so difficult, and yet so tempting, to "find out what cannot be done, and then to go and do it!"

I feel serious promptings here to have a fling at science that will surely bring down the wrath of our President on my unfortunate head. I will try to ameliorate him by saying that science demands our greatest respect. No one can have more reverence for science than I have myself—when it keeps its place. But we are suffering from science, and fancy is dying out of the land. It is doing serious harm to photography as a picture-producing art. When a student ought to be studying the construction of a picture, and developing in his soul the art of lying, he is led away by the flickering *ignis fatuus* of science, and goes mad over developers. "Another new developer" has more effect on the tender feelings of the brethren of the camera than would the advent of a poet-photographer. This suggests a variation on Rejlander's *Two Ways of Life*. One youth travels along the pleasant and virtuous walks of art, not listening to the Sirens of Fact; but dozens of others are decoyed to the worser way, and are soon lost in the seductive vanities and subtleties of science. They last long enough, perhaps, to modify a developer—with which science, however, tells them they can do little or nothing—and are heard of no more, except in the multitudinous platitudes used in the endless discussions of abstractions in society papers; and the scientific dream of the future is an Institute of Photography from which Art is to be excluded. Art will be very glad to part company.

Let us be generous and admit that Science has its good points, but it is doing a good deal of harm in the world. It is robbing us of our illusions. The science of History has defrauded Richard III. of his hump, made Henry VIII. a moral character, and gone audaciously nigh to proving that Jack the Giant-killer never existed. We are bored by the tedious papers of those who "have not the wit to exaggerate nor the genius to romance," and a synonym for dulness is a lecture at the Royal Society. But scientists are not without their hilarious moments. In our own Art I cannot help thinking that scientists are trifling with a serious subject when they tell us that we cannot do as we like with our developers, or when they bring logarithms to bear on picture-making. But the humour is not all on one side, and we not unfrequently enjoy a smile at the prodigious engines they sometimes use to crack our poor little nuts.

What has science to do with art, except to provide materials for its use? It is only of late that art has, on the one hand, been made to depend on absolute scientific truth; and, on the other, by the same writers, been proved, in the case of photography, not to be an art because it cannot deviate from truth. It is merely an incident, an accident, a detail; call it what you will, that science, sometimes of the highest and most distracting kind, is connected with picture-making photography. The science that deals with the nature of the image, or the calculation of the curve of a lens, is a very distant cousin indeed to picture-making by the use of photographic materials. The use of materials invented by others for a definite purpose can scarcely be called science. No scientific theory should be allowed to have weight with an artist who has practised his art successfully for years, and knows what he wants and how to get it. If, for instance, I was told that it was proved by science that the negative would not yield all the tones of nature, I should reply that many years' practice had convinced me of that well-known fact, but the mere circumstance of it being proved scientifically did not alter the facts, or further limit the tones. When it was proved scientifically to Diogenes that he could not walk round his tub, that humorous philosopher settled the matter by walking round that desirable residence. I am afraid I have used this illustration somewhere before, but let it pass. In art, the artist sees his results, and it is for him to judge, from his knowledge of art and nature, *not science*, whether his results are true, or, at any rate, if they lie properly and are what he wants. The artist has to do with appearances, the scientist with facts. It is not enough to say this is not true. The question is, Is it true enough for artistic purposes?

I have alluded to development once or twice. Two very clever scientists, whom I much respect, Dr. Hurter and Mr. Driffield, have proved to everybody's unsatisfaction that photographers have no control over the gradations; but this does not alter the fact that—to put the simplest case—he knows when a negative is over or under-exposed, or developed too dense or too thin to properly represent his idea of nature as far as in him lies, and his art will allow. Then

there has been another great attempt made to show that the perspective of photography is not scientifically true. If the attempt was successful, which is very doubtful, *Who cares?* It has been true enough not to be found out for fifty years, and that is good enough for photography. Can it have been the want of truth that has unconsciously compelled artists since the beginning to admire the truth of photographic prospective, and rely on its veracity? Here is another paradoxical nut to crack.

But my business is not to make a feature of the truth of any part of photography. On the contrary, I want to clear its character of the unartistic virtue of being nothing but a truthful, inevitable, stupid purveyor of prosaic fact.

Painters sometimes trust to us for truth; the Law Courts are becoming more wary, and appreciate our deviations. I was once found fault with by an artist for "altering" a photograph, on the plea that it would mislead a painter if he wanted to copy it. I found he *had* copied it before he saw the scene, and when he afterwards compared his picture with it, he found a clump of trees that should have appeared on the left transferred to the right. I had made the alteration by double printing, and improved the composition. *I did not* want a mere local view. I don't know that there is anything more exasperating than for a painter to take it for granted that it is a photographer's business to play jackal to his lion, and hunt up food for him; but it is a blessed truth that we *can* deceive him if we like. Painters ought to be more grateful to us than they are. Besides providing some of them with subjects, we have taught them what to avoid—educated them on the Spartan and Helot principle—and art has vastly improved during the half-century of our existence. We have made the column and curtain background absurd. When our art was born, painters thought nothing of violating perspective by placing the horizon as low as the feet of their portraits, and made no difficulties about hanging heavy curtains from the sky, and we are still fulfilling our useful mission of showing artists the ridiculous things they ought not to do, but it is asking too much to provide subjects for them—idea, composition, and detail. A painter should never use photography until he is capable of getting on without it, and then he should make his own photographs. To copy another man's work is not honest, and is a lazy and mischievous method of attempting to make a living.

I am afraid I have filled my space without giving as many specimens as I could wish of the possible delinquencies and untruthfulnesses that art requires and photography can accomplish; but I hope I have shown that, if it cannot lie like paint, it has the merit of approaching it in mendacity.

I will conclude with another illustration of the capabilities of our art for useful falsification. I once knew a photographer (it sounds better to put it that way) who was employed, for the purposes of a Parliamentary Committee, to make a series of photographs showing that one place was much more picturesque than another. Some ugly gas-works were to be erected, and it was desirable to place them on the least beautiful of two spots. It may be also mentioned that it was likewise necessary that they should be placed on the site that best suited the promoters. Both places were very picturesque, but in the photographs it was easy to see the one site was a little rustic paradise (with suitable figures and fine skies), and the other a dreary desert, all foreground of the plainest! Yet both were true to fact, and they had the intended effect.

In conclusion, let me express the pleasure I feel in being afforded the fascinating opportunity of saying a few humble words in praise of lying in a room which has been saturated with truth and fact for more than a hundred years—ever since, indeed, Barry "restored the antique spirit in art" by painting his anachronisms on the walls, and from which building emanates the prospectus of the Chicago Exhibition, which honours our art with the crowning paradox of classing photography with Instruments of Precision. H. P. Robinson.

ON THE PRESERVATION AND DETERIORATION OF GELATINE NEGATIVES.

Perhaps within the whole range of one's photographic experience there is scarcely anything which causes more annoyance and regret to a careful worker than to find that, after all the care bestowed in the production and subsequent proper storage of negatives, a deterioration or decay, sure and certain in its action, will set in, and over which there is no control.

Among the numerous forms of deterioration, perhaps one of the most annoying is that of the sudden appearance of spots or specks of varying shapes, and frequently of a dark brown colour, which, after a time, will change to a lighter tint, and eventually become almost transparent. These brown or yellow spots have from time to time given rise to a considerable amount of discussion, and various have been the opinions formed and expressed by experienced workers as to their cause. All seem, however, to agree that it is almost useless to hope for any success to attend any attempts to remove them when once they have taken root in a negative. Some workers have advocated a certain method of treating such flaws to a weak bath of cyanide, &c., as a means of getting rid of them; but such, I fear, is by no means a certain cure for this trouble, and in many other ways a very doubtful one, for the whole range of tone in the negative is almost sure to suffer when such a treatment is resorted to, and hence more harm than good is likely to result.

Intimately associated with the question of the deterioration of negatives is that of their preservation, and therefore we find the common practice resorted to of applying a coating of varnish or some other suitable medium, such as plain collodion, to insure the surface of the film against damage of various kinds. It has been claimed by some of our most experienced workers in photography that, once a gelatine film free from defects has received a coating of collodion, and then a further coat of varnish, that such is an absolute protection against all atmospheric influences, and proof against surface contaminations from such as damp printing paper, &c. I am afraid, however, those who hold these views claim too much—at least, it has not been so in my experience—and in the course of this article I shall be able to show and offer incontestable proofs that such a treatment is absolutely useless to ward off or prevent a certain disease or decay setting in on gelatine films on glass.

Doubtless, the common practice of varnishing negatives, as a precaution against certain injuries and accidents commonly met in with almost daily in every printing room, is quite a wise precaution against even such seemingly trivial matters as a drop of water or saliva from a printer's moustache; for, when any adhesion of the printing paper takes place with the negative film, it is an easy matter to remove the varnish, and get the plate recoated before any damage is done, and many a valuable plate has been saved by such an action taken promptly.

But there are numerous other forms of deterioration met in with in gelatine negatives which no coating of varnish seems able to prevent, and the knowledge of this has raised the question in many minds that, after all is considered, if it is not quite as well never to varnish. I know more than one worker whose hairs are grey with photographic experience who entirely discards varnishing in every way, alleging that such is quite likely to injure an otherwise healthy film, and do more harm than good.

For some years this subject has given me a good deal of thought, and I have studied somewhat closely the various forms of deterioration and flaws commonly met in with in gelatine plates, in the hope of being able to form a somewhat definite opinion as to their cause (at least, in some particular kinds of them), and, if possible, hit upon a remedy as a safeguard against such; and, perhaps in this more than any other phase of photography, the old saying holds good, viz., "To find out the cause is to effect a cure."

So far back as the year 1886 I began to give some thought to this subject, and I confess that I was among those who, on theoretical grounds at least, formed the opinion that, when a gelatine negative film was subjected to a coating of collodion and finally varnished, such was proof against all atmospheric influences. Before long, however, I had a rude awakening.

It transpired that in the summer of 1886 I had occasion to use some extra rapid plates, which were coated with an emulsion that was prepared by what is known as the ammonia process; these plates, I may say, were made under my own observation, and at the time yielded negatives, when developed with pyro and soda, that were all that could be desired—hence the extra precaution on my part to protect a good thing when I had got it. So they were straight away treated as follows:—

The films were first rubbed with a silk handkerchief, then coated with a plain collodion, and finally, on top of that, they got a good coat of spirit varnish. For a long time all went well, and not a single one of the batch showed any signs of deterioration, or spots or specks of any kind. During the winter of 1886 and spring of 1887 they were carefully stored away with other plates in mahogany, grooved boxes, placed in a dry parlour cupboard, and, so far as I could discern, were in no way subjected to any sudden change of temperature and damp. In the autumn of 1887, however, I had occasion to throw off a good many prints from one of these negatives, and all went well—no signs of spots or deterioration in any degree, and so the winter of 1887 passed. In the spring of 1888, however, judge of my disgust to find one of my pet negatives attacked by a disease in the shape of minute spots of a brown colour, and these had

the appearance of eating down into the film. It was quite evident a decay of some kind had set in, and had been progressing all the winter. My first thought was how to save the negative, and so I immediately set about removing the varnish by means of methylated spirits, thinking that by so doing I would get behind the spots. But here I was mistaken; the disease was deeper down, and had actually penetrated into the gelatine film through the coating of collodion.

This negative I now took especial care of, not as one ever likely to afford me much pleasure in the way of printing, but as one that would yield me some information and insight into the nature and behaviour of the insidious disease that had set in, and so I have carefully watched these spots from time to time and noticed their appearance under the microscope, in the hopes of being able to form some definite opinion anent them. One thing I had learned, viz., that no coating of varnish or collodion could be relied upon as a preventive of this form of decay or disease, which, to my mind, was clearly inherent in the gelatine film itself.

Spots or specks, and numerous other flaws which clearly come under the category of defects and deterioration, are, properly speaking, divisible into three classes:—In the first place, we have a certain kind of spots which are clearly traceable to the shortcomings of the plate-maker. Secondly, we have numerous forms of surface defects and stains that arise from sheer neglect and ignorance on the part of the worker. Thirdly, we have by far the most dangerous and insidious form of spots that are inherent in the film itself, and which, so far as I know, we have no power to prevent.

I shall treat of these latter defects first. When any one for the first time views through a fairly good microscope a gelatine negative, using, say, a one-inch power, they cannot but be forcibly impressed with the great beauty and evenness of the deposit of metallic silver which, on development, has taken the place of the sub-bromide of silver, formed on exposure of the plate to light. This metallic deposit varies, of course, according to the shadows or high lights of the negative; but the grain, when the film is in a healthy state, and not disturbed by any defect or decay, is always found to yield a beautifully even appearance of a dark grey steel colour, something like the grain seen in fine emery paper, the grain being beautifully even and free from all lumps and irregularities. The appearance of a portion of the sky, as seen when viewed through the microscope with a one-inch power, shows that the metallic silver is evenly distributed, there being no flaws or disturbing element present.

In my next I hope to refer to the altered aspect of the film when decay has set in.

T. N. Armstrong.

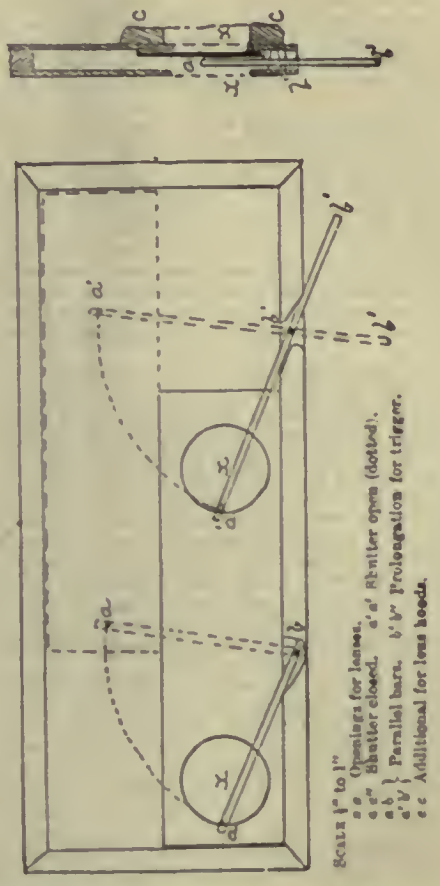
A STEREOSCOPIC SHUTTER.

Beyond the invariable *desiderata* common to every shutter there are one or two points specially requisite in one for stereoscopic work, one being absolute synchronism of opening, the other greater length of exposure to foreground than sky, the foreground objects being of such primary importance in a good stereograph. Both these points are difficult to obtain with the double cap, and a shutter is almost a necessity. One can buy lovely shutters, of course; but there are so many to whom every item of expense is important, that the description of a most effective and easily made shutter will be useful. I do not know if it is at all original—probably not. Consequently, if such a shutter has been described before, I hereby apologise. If it is any one's patent, I must ask the Editor to cremate this carefully. But I believe it is, at all events, new to many.

The diagrams will almost speak for themselves. It will be seen that the shutter consists as a whole of a back and front covering board perforated for the lenses, and that, in the space left between these back and front boards, works what is practically one blade of a parallel ruler, motive power being supplied by the extension of one of the bars, on which the "blade" forming the shutter proper is hinged. This shutter rises until the bars are just *beyond* the perpendicular, when the lenses are uncovered, and the shutter will remain open without attention, a touch of the "trigger" extension of the longer bar returning it to "closed." It will be seen at once that the exposure may be made pretty rapidly—quite enough so for any ordinary purpose, and as rapidly as any stereoscopic picture is likely to be taken.

The diagrams are drawn to scale half size. The one drawback, which, owing to the flatness and lightness of material used in a small one, is in the length of the whole shutter being slightly beyond that usual. The *material* of the shutter is of one-eighth of an inch (or less) cedar (say the useful cigar-box), the shutter proper being of the same. Parallel bars of brass or vulcanite. Except for the lens openings, and the one very small aperture necessary for the prolonged bar, the whole being enclosed, there is no difficulty or extra careful fitting required to ensure light-tightness. The lenses are attached by means of an extra half-inch wooden slip perforated to fit them, glued, or screwed to the back.

The diagrams are planned for a pair of rapid landscape lenses, mounted at the regulation three and a quarter inch centre. The parallel



bars *a b* and *a' b'* are pivoted at what are the most economical points, the pivots at *a* and *a'* on the moving portion being on the centre line at its intersection with a circle corresponding with the lens apertures. In making up the shutter the main points to be observed are that the holes in the bars *a b* and *a' b'* are at exactly the same distance. It is best to put one on the other, and drill the two simultaneously. The length of these bars is, of course, determined by the height to which the shutter is raised; but the distance between the points *a a'* and *b b'* must be exactly the same, or the shutter will not open evenly. In the plan the distances are three and a quarter inches.

The separation between the front and back boards is just enough to allow the shutter to work easily. As will be seen, the bottom slip of wood by which they are separated is recessed to take the parallel bars, the shutter therefore fitting closely to the back covering board and lenses, there is no chance of any stray light entering.

The shutter, with a few careful measurements, will be found very easy to make and very satisfactory in working. The foreground exposure is far longer than that for the sky, and may be of any duration. There can be no vibration, and the whole thing is very light, and costs a little trouble and some screws.

Rev. C. W. Whistler.

THE ACID ACTION OF DRAWING PAPER OF DIFFERENT MAKES.

[Chemical Society.]

In a communication to the British Association, *On the Fading of Water Colours* (*cf. Chemical News*, Vol. LIV. p. 263), I showed that moisture and acidity were the chief causes of the fading of certain pigments. The acid in the air of towns is produced from sulphor in the coal, in the air of rooms from the excessive amount of gas which is burnt, and in certain colours according to their mode of preparation. It was suggested that even the slight acidity of drawing papers might be expected to facilitate chemical change, the action in each case being a gradual one. I had experimented with various kinds of the best paper in use, both of

old and recent manufacture, and had come to the conclusion that such papers were invariably acid, even those of the most excellent quality. The fact was accounted for as follows:—The fibre of which the paper is made is steeped in dilute sulphuric acid, and the subsequent washing with pure water does not entirely remove the acid from linen fibre, of which the best papers are made. I have actually found fine linen to retain traces of acid after it has been steeped in frequently renewed pure distilled water for a period of three weeks. The acid seems to combine with the fibre, and the resulting compound is only slowly decomposed or dissolved by the action of water. Such linen gives a blue colour when an aqueous solution of iodine is dropped upon it. There was no intention to convey the idea that the paper contained free acid in such quantity that it could be easily removed by washing, or that it would affect *litmus paper*, which generally is not a sensitive agent. The samples of paper exhibited at the meeting were carefully tested in the following manner:—A pure and neutral solution of azolitmin, prepared from litmus, was allowed to drop upon the paper and soak into the fibres; the edges of the drops were then examined, and found to be red. The bulk of the liquid was then removed by a piece of the same paper, with the result that in every case a red spot was seen, which dried red. Another mode of testing was as follows:—A clear sable brush, washed in distilled water, was used for applying a wash of pure neutral azolitmin solution, as if it were a pigment; such washes turned red upon the paper.

Professor Church, in his valuable work on *The Chemistry of Paints and Painting*, published in 1890, remarks that he is unable to endorse my statement that the best drawing papers have an acid action. He finds, in fact, that sized papers are generally neutral to test-papers, and that inferior papers are more often slightly alkaline than acid.

As some doubts may be entertained as to the quality of the papers examined by me, it may be well to state that they were all of the best quality, most of them being of Whatman's make. That no question may arise on this point, I have tested the samples named below in three ways: first, by dropping litmus solution upon the paper; secondly, by washing with a sable brush; thirdly, by steeping strips of paper in pure distilled warm water, and testing the water for acidity, and also for sulphates. The acid action was recognised by a pure litmus solution, by an ordinary laboratory preparation, and by a carefully prepared solution of helianthin, though this last agent is not very sensitive.

The results are identical with such as I obtained on former occasions. The description of the samples and their actions is as follows:—

1. Whatman's hand-made paper, 96 lbs., old make. Washes, acid; drops, acid; water, decidedly acid. Large precipitate with barium sulphate insoluble in dilute chlorhydric acid.
2. Whatman's double thick imperial, 140 lbs. Washes, acid; drops, acid; water, decidedly acid. Large precipitate of barium sulphate, as with No. 1.
3. Whatman's double elephant, hand-made. Washes, acid; drops, acid; water, strongly acid. Large precipitate of barium sulphate, as with No. 1.
4. Whatman's hand-made, 72 lbs., 1887. Washes, acid; drops, acid; water, decidedly acid. Large precipitate of barium sulphate, as with No. 1.
5. Saunders's hand-made. Washes, acid; drops, acid; water, decidedly acid.
6. Hollingworth's machine-made paper. Washes, barely acid; drops of strong litmus, neutral in colour; water, very slightly acid, almost neutral.
7. Arnold's unbleached hand-made paper. Washes, acid.

No further tests for acidity were recorded.

All these samples were procured, especially for the purpose of these tests. It will be seen from these notes that there were good grounds for attributing an acid action to even the best of drawing papers. In other words, if a very sensitive solution of pure litmus be applied to paper in the same manner as a strong pigment, as, for instance, in delicate washes, the action is, in almost every case, distinctly acid; but, if a drop of a strong solution be allowed to sink into the paper and dry up, its colour may be so slightly changed as to appear violet, leading to the inference that the paper is neutral. The strength of the solution of litmus, and the manner in which it is applied, must therefore be taken into account, because the quantity of the purple colouring matter in contact with the paper may be more than sufficient to overpower the red tint caused by the acid present in the moistened material. It is, therefore, extremely probable that there has been no difference between the opinions of Professor Church and myself, but only an incomplete understanding as to the degree of acidity of the paper. Solutions of helianthin painted on the various samples of paper gave at first a pure yellow tint, which gradually changed to a colour intermediate between rose colour and yellow. Very dilute solutions, washed on freely, showed after some minutes a pale rose colour, mixed with a yellowish tinge.

A sufficiency of acid yields a fine rose tint with such a solution. Hollingworth's paper did not show in any degree an acid action with helianthin, although it gave a slight indication with litmus.

Discussion.

Mr. Wade remarked that perhaps the sulphate detected by Professor Hartley was derived from thiosulphate, which, it was well known, was used as an antichlor in manufacturing paper.

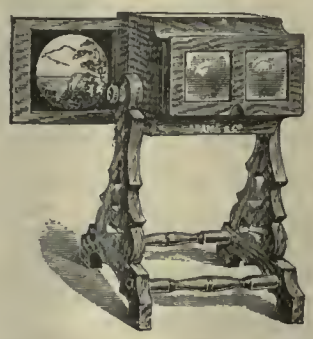
Mr. Groves said it would be desirable to know more of the history of the papers. Was gas burnt in the room in which they were stored, and were the sheets examined taken from the tops of the packets? If so, it was possible that the sulphuric acid was derived from the gas; it would be desirable to test the centre portions of sheets taken from the middle of the packet.

Professor Hartley's remarks on this criticism are as follows:—The circumstances are not within my recollection, and I am unable to make inquiry at present, but drawing paper in sheets is kept in drawers, at a height of not more than three or four feet from the ground, and carefully protected from dust and damp. As a rule, the samples tested by me have been taken from the middle sheets of sketch blocks prepared from Whatman's hand-made papers, and purchased from Lechertier, Barbe, & Co., Regent-street. Imperial and double elephant were the kinds most used. I am well acquainted with the effect of a sulphurous atmosphere on paper, but cannot think that the acidity to which I refer is to be attributed to such a cause. W. N. Hartley, F.R.S.

Our Editorial Table.

Adams's Binocular Pantascope.

Messrs. Adams & Co. (Charing Cross-road and Aldersgate-street) having now completed their Binocular Pantascope, we have been afforded an opportunity of examining it. As will be seen from the drawing, this pantascope is a parlour-table instrument for viewing



lantern slides by both eyes. In form it is elegant, and it is well made. Messrs. Adams make them in three styles: one for lantern slides pure and simple; a second and a third with a chromatrope attachment behind, by which the light passes through tinted media, and imparts effects of natural colour to the scene under examination.

This system of inspecting lantern views is so good, that it is certain to be generally adopted as an alternative to projecting them by the lantern, and a parlour table on a winter's evening will scarcely be complete without two or three of these instruments upon it. The better class of pantascopes have an ingenious arrangement by which small paper photographs also may be viewed.

The binocular pantascope sells at 25*s.*, 31*s.* 6*d.*, and 42*s.* respectively, according to the style.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

MARCH 2.—Technical Meeting, Mr. J. Traill Taylor in the chair.

Mr. T. R. DALLMEYER described the new form of his tele-photographic lens, consisting of a 2 R patent portrait objective and a symmetrical negative combined. The advantages of this system over that which he had originally introduced were that correction for eccentrical pencils was obtained, and thus the field was flattened, while the power of using the back lens of the portrait objective corrected negative aberration. The full aperture could be employed for distant as well as near objects. He produced comparative pictures by Mr. M'Kenzie, of Glasgow, illustrating the powers of the tele-photographic lens.

The CHAIRMAN said they had elicited two important facts that evening, namely, that the telescope principle could be applied to existing Dallmeyer patent portrait lenses, and that a compound symmetrical back lens could be used instead of the Galilean eyepiece. He congratulated Mr. Dallmeyer on his improvements. Some present might wish to know, in reference to the large picture shown, what would be the difference between its definition and that of a picture enlarged to the size from a small negative.

Mr. DALLMEYER said the result would not be so sharp. With the tele-photographic lens they had been able to get details not revealed by an opera-glass.

Mr. E. Clifton exhibited Messrs. Beck's Frena hand camera, which takes forty cut films, lantern-plate size. In the frame were a series of notches, and between each film was a piece of cardboard having similar notches, so placed that the respective notches did not register. The mechanism was so arranged that after each exposure a film and a card dropped out of position. The film could be moved up to the moment of exposure, and thus a swing-back movement could be obtained.

Mr. R. G. Mason exhibited his new combined lantern and table microscope.

Mr. H. CHAPMAN JONES, referring to a misunderstanding which had arisen as to what he had said on a previous occasion in reference to copying on an enlarged plate, explained that what he did was to photograph a square, subdivided into smaller squares, on a sloping plate. The angle of this plate was 21°. In copying the picture equal size, the angle the negative was placed at was 21°. Thus the original angle required an angle of 21° to correct it. The scale of reproduction was proportionate to the various parts of the plate and the lens plane. The angles were purely accidental, and depended upon the distance of the plate from the lens.

A large collection of silver prints, made prior to 1862, and lent by Messrs. H. W. Foxlee, Colonel Mitford, F. R. Currey, J. Traill Taylor, F. Bedford, W. Haviland, E. Clifton, and the Photographic Club, was on view.

The CHAIRMAN said they would see from the collection that silver prints did not necessarily fade.

Mr. H. W. FOXLEE said his prints were produced under circumstances which, according to modern notions, should have conduced to their fading long ago. One feature had, perhaps, conduced to their permanence, namely, that the paper was strongly salted and highly sensitised, while the pictures were mainly printed under tunnel, which, in some cases, took many hours. Perhaps this toning contributed to permanency, because all that time fixing was going on. For the last twenty years his prints had been stored away as lumber. Some of the pictures had yellowed, but the prints were nearly all unaffected. With some similar prints kept under similar conditions, the yellow had gone right through the pictures.

Mr. W. ENGLAND thought fading was chiefly due to the fact that prints were not properly washed. He had, in fact, proved it to be the case.

The CHAIRMAN said he had had a fixed, but incompletely washed print in his possession for many years, which had retained its pristine vigour to the very last. Hypo did not necessarily act in a deleterious manner so long as the print was kept dry.

Mr. FOXLEE attached more importance to thorough fixing than to washing. He would rather have incomplete washing than incomplete fixing. Mr. Foxlee had fixed and dried prints, and placed them in hypo, without noticing any subsequent change. Some of his (Mr. Foxlee's) prints on the wall produced in 1862, had only been washed for two hours.

In closing, a vote of thanks to those who had lent the old pictures, the CHAIRMAN said nothing better than the latter was produced at the present day, either as negatives, ortho- or isochromatic effects, artistic compositions, or production of an optical tool.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 17.—Mr. J. Traill Taylor in the chair.

Mr. W. Bouts was elected a member of the Association.

A question from the box asked whether, with wet plates, a forty-grain bath was better than a thirty-grain bath for line work, and was a plain iodised or bromo-iodised collodion to be preferred?

The CHAIRMAN observed that in such a case great crispness and a considerable degree of intensity were wanted. The usual way with those photographers who worked reproduction processes was to develop the negatives clearly, and intensify with mercury and ammonium sulphide. He thought a thirty-grain bath would do. A final intensification with potassium cyanide and silver cyanide gives great intensity.

Mr. A. L. HENDERSON advocated a twenty-grain bath. Weak baths gave the same intensity as strong ones. The method mentioned by the Chairman was practised at Southampton.

In reply to a question, "What are the advantages of a bioular lantern, and in which way is exact centering effected when effect slides are shown?" Mr. T. E. FRESHWATER said the only advantage was that one got a change of pictures by dissolving instead of pushing them through. In some respects, as compared with a single lantern, it was at a practical disadvantage. The cheapest way of effecting the centering was to have two pieces of glass carefully fitted into the frames and have lines drawn on them, and make the two discs to register. It was a very simple way, but wanted careful consideration in measuring up and adjusting; but it was not absolutely necessary, as they could have two front lenses of the same focus, and make the two discs coincide. For many effect-slides, they must have a triple lantern. Continuing, Mr. Freshwater said that the Association wanted a gas regulator for its lantern, and he was pleased to say that Mr. R. R. Beard had presented one to the Association, which he (Mr. Freshwater) had brought with him that evening.

The thanks of the meeting were voted to Mr. Beard and Mr. Freshwater.

Mr. James Martin's ice-crystal photograph being exhibited, Mr. A. COWAN asked whether any salts were in the water. The crystals did not look like pure ice crystals.

The CHAIRMAN remarked that water, in freezing, ejected all foreign matter.

Mr. A. HADDON said that was so. Faraday dissolved some chlorine in water, and froze it, and found the water resulting from the liquefaction of the ice crystals absolutely free from chlorine. It was possible to use frozen sea-water to quench thirst.

The CHAIRMAN had sometimes strengthened the silver solution by freezing it and removing the ice. This method gave a highly concentrated solution.

A letter was read from a German photographer, inquiring if the Secretary of the Association could give him any information as to whether English photographers worked on Sundays.

Mr. A. L. HENDERSON said he had worked on Sundays, and had paid the penalty for it. He had many times been before the Lord Mayor, and fined 5s. for the offence. It was a cheap advertisement for him, and he did not think he had been ruined either mentally, spiritually, or physically by taking photographs on Sunday.

Mr. W. E. DENNENHAM exhibited a small lamp with a little cotton-wool placed at the small end, which he used as a filter for collodio-bromide emulsion. He had used it with great success, and the whole thing had only cost a penny. In reply to Mr. Henderson, he thought washleather would stop too much bromide.

The CHAIRMAN had forced collodio-bromide emulsion through washleather by means of a piston.

Mr. A. MACKIE used a bottle with the bottom cut off, a little wool being tied over the aperture as a filter.

Mr. W. E. DENNENHAM showed a collodio-bromide transparency, made with the new methylated spirit, which he found did not hurt the emulsion at all.

Mr. A. MACKIE had had four samples of the new spirit, and found every one of them different. In ascertaining how much water was required to produce permanent milkiness, he found that in three cases it was twenty per cent., and in the other thirty per cent.

The CHAIRMAN said that they would soon be using the old methylated spirit again.

Mr. MACKIE had investigated samples of the old kind of spirit. The substance used was not in every case wood naphtha, and sometimes had a smell absolutely distinct from wood naphtha.

The remainder of the evening was devoted to an exhibition of lantern slides by Messrs. Maitland, Everett, Bouts, Rawlings, Austin, Cooke, Simmonds, Chang, and Beckett.

North London Photographic Society.—March 15, Mr. Hedley M. Smith in the chair.—The business of the evening was a lantern-slide competition, the slides being made from four negatives supplied to the members for the purpose. The comparison was made by means of two lanterns, identical in their optical construction, and carefully adjusted to give equally lighted discs on the screen. Two similar slides being thus shown side by side, the inferior one was removed, the best remaining until displaced by a better. The four sets having been thus disposed of, and voted upon, it was found that Mr. J. Oakley had taken three first places and one second with Mawson's lantern plates (pyro development); Mr. B. J. Grover, one first place and one second with collodio-bromide plates, the emulsion being his own preparation; Mr. E. M. Groundwater, two second places with Ilford Special plates (hydroquinone developer). Arrangements have been made to obtain the loan from the Photographic Society of Great Britain of Dr. Jeserich's paper on *Photography as applied to the Detection of Crime*, which will be given, with the original illustrations, at the next meeting, on Tuesday April 5, at a quarter-past eight p.m. Visitors are invited.

Hackney Photographic Society.—March 17, Mr. Beckett in the chair.—The members were reminded of the loan collection of lantern slides. The idea was to form a collection, which could be lent out to members on application. A result was shown, in which comparison had been made between alpha and ordinary lantern slides, and it was generally thought that the alpha was the better. A paper on *Lenses* was given by Mr. W. P. Dando, tracing the subject from how light was obtained, and the effect brought about by the lens. Numerous diagrams were used by Mr. Dando to illustrate his paper. Astigmatism, spherical aberration, and every point, fault, and otherwise was exhaustively dealt with by the lecturer, and in a very comprehensive manner, so that the merest tyro could understand it.

People's Palace Photographic Club.—March 18, Mr. R. Beckett in the chair.—This being the last members' lantern night, a number of slides were put through the lantern. Some slides by Mr. G. Kendall, of bronzes, vases, and tables set for dinner, proved good subjects for lantern slides. Mr. S Beckett showed a number of slides, some of which, being coloured, elicited criticism. An all-day outing to Maidenhead and Cookham for Easter, to which ladies were invited, was announced.

Polytechnic Photographic Society.—March 18.—The Secretary read a paper on *Collodion and its Apptication to Commercial Photography at the Present Time.* Although wet plates had been used in the early days for portrait work, they are seldom employed now for that purpose; some very successful negatives by Mr. W. E. Debenham were shown as illustrations of the old-time process. The principal uses for wet plates now are for photo-zincography, photo-lithography, photography on boxwood for engravers, and for lantern plates. Examples of these processes in their various states were shown, the copies, negatives, photo-prints, transfers, and finished blocks, rendering the lecture thoroughly clear. Next meeting, March 29, when Captain C. E. Gladstone will lecture on *Westminster Abbey.* Any interested photographer may obtain a ticket for admission by sending stamped addressed envelope to 309, Regent-street, W.

Kensington and Bayswater Photographic Society.—March 21.—A meeting for the formation of the Society was held at the Horbury Rooms, Kensington Park-road, Mr. C. W. Brumwell in the chair, and about forty others being present. It was resolved that the Society should have three officers only, namely, a President, a Secretary, and a Treasurer. The election of a President is left over until the next meeting. Mr. C. W. Brumwell was elected Secretary, and Mr. F. A. Hahn, Treasurer. The meetings are to be held at half-past eight p.m., on the second and fourth Fridays in each month until the end of May. The subscription is to be 5*s.* to the end of the session (September), and not to exceed 10*s.* annually. The Chairman for each meeting is to have been elected at the previous meeting. The next meeting will be held on Monday, March 28, which will be devoted to the exhibition of lantern slides. Ladies and gentlemen wishing to join the Society are requested to send their names to the Secretary, whose address is 7, Lower-terrace, Notting Hill, W.

Richmond Camera Club.—March 18, Mr. Cembrano in the chair.—Mr. Faulkner gave an address on *Makeshifts*, postponed from a former occasion. A more appropriate title would have been "Home-made Apparatus," for the various contrivances shown and explained by Mr. Faulkner, besides being beautifully made and models of compactness, were admirably designed to meet the various purposes for which they were intended. They comprised a rocking developing dish, with adjustable cover to wholly or partially exclude the light; a printing frame, with double rebate for holding coloured glass, vignetter, &c., and a simple catch for the back springs, avoiding the risk of shifting the paper in pressing the spring home; a box for exposing bromide paper, lantern slides, &c.; a combined shutter and sunshade, a drying box for negatives, a lamp for making contact exposures, and, finally, a most compact and business-like quarter-plate hand camera, which could give points to many a much-advertised "smallest thing in the market."

Croydon Camera Club.—March 14, the President in the chair.—Messrs. W. H. Heape, J. Smith, and T. B. Roberts were elected members. Mr. D. E. Goddard read a paper on *Silver Printing*, which was well received by a considerable gathering.

March 17.—The annual dinner of members and friends was held at the Greyhound Hotel, Mr. H. Maclean, F.G.S. (the President), being in the chair, supported by Mr. E. J. Wall (Editor of *Amateur Photographer*) and Mr. B. Gay-Wilkinson (the Vice-President). An enthusiastic and numerous gathering of members spent a decidedly enjoyable evening, the interest being divided between the attractions of music and of speeches, devoted to matters more or less photographic in their subject-matters. March 28 is a Lantern Night; members' slides. On April 4, Lieutenant-Colonel Gale gives a lecture, entitled *Rambles, Rural and Pastoral*, illustrated by a selection of his own slides.

Midland Camera Club.—March 18, the President (Dr. Hall Edwards) in the chair.—Mr. John Howson, of the Britannia Works Company, demonstrated the value of isochromatic plates. Mr. Howson was extremely practical, and by developing two plates exposed behind a coloured screen, the light used being magnesium wire, proved conclusively the advantages of an isochromatic plate, even without a yellow screen. His points were clearly put and understood. Mr. Bentley showed the difference he had obtained by the use of an isochromatic plate; Mrs. Welford showed a sixty-times Fry's film of a difficult church interior, to which she gave twenty minutes' exposure, and the result showed little or no halation, and also some hand-camera shots on isochromatic films. Mr. W. D. Welford (Hon. Secretary) showed the Daisy printing frame, the Ownligood developing tray, and manipulated the Todd-Forret flash-lamp.

The Exhibition of old silver prints produced prior to 1862, to which reference is made in our report of the parent Society's last meeting, will remain open for a few days, so that those who would like to have an opportunity of inspecting them may do so.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

RATIO OF GRADATION.

To the Editor.

Sir,—Messrs. Hurter & Driffield say, on page 8 of their pamphlet, "By no means at his" (the photographer's) "disposal can he alter the ratio existing between the amounts of silver reduced in the various parts of the negative; they are regulated entirely by the exposure." In their reply to Mr. Michael they state they do not hold that the "ratio is invariably the same whatever the developer employed." Mr. Phillips accuses me of discourtesy in saying these gentlemen forgot what they wrote. His conceptions on the ethics of debate must be peculiar, for if these gentlemen did not forget, how will he explain the above contradictory statements? He is guilty of rudeness to me or of unworthy insinuations against Messrs. Hurter & Driffield, of the value of whose paper I expressed my high appreciation. He absurdly gives me a challenge to prove that the ratio can be altered at will and in the same paragraph implies that Messrs. Hurter & Driffield's experiments show that it can be so altered. Why, then, should I give further testimony? The question altogether is a mere side issue, but he need not throw surreptitious mud at these able investigators.—I am, yours, &c.,

Free Lance.

COPYING INCLINED PICTURES.

To the Editor.

Sir,—*Apropos* of a recent discussion at the London and Provincial Photographic Association, I beg to point out to your readers that my equations on page 859 of The British Journal Photographic Almanac, 1892, supply the necessary details for solving such questions.

Suppose I photograph a diagram 8 inches square, with a lens of 10 inches principal focus, and reduce the same to 3 inches square, when both object and camera-back are square to axis of instrument the equations give the conjugate foci as 36·67 inches and 13·75 inches respectively. Now, setting the diagram 20° out of square will increase and diminish the greater focal distance by 1·4 inch at each side; assuming the camera-back to remain square with axis, I find that the image will be 2·89 inches and 3·11 inches high at the two sides. Now, to correct this distortion, I copy with the same lens, and the equations show that I have to set the original photograph, as well as the camera-back, at an angle of 75½° with the axis, which will represent an angle of 29° with one another. Should, however, the camera-back have been swung in making the first copy, for the sake of getting better definition, the image will be 2·84 inches and 3·16 inches high at the sides, and then the original photograph and camera-back will require to be set at 69½° with the axis and at 41° with each other. I have often solved similar questions by my equations, and found the result correct in practice.—I am, youre, &c.,

J. A. C. Branfill.

DEPTH OF FOCUS.

To the Editor.

Sir,—In his letter published in The British Journal of Photography last week, Mr. Clifford E. F. Nash takes exception to my statement in regard to depth of focus depending on the actual size of the stop, uninfluenced by the focus of the lens (p. 167 in your issue of March 11).

It is certainly correct that the circles of confusion with different lenses will be the same for the same diameter of stop only when the images are equal in size. In photographing from a given standpoint with lenses of different focus, the circle of confusion will be proportionate to the size of the image or focus of lens, the actual measurement of the stop being the same in either case; so that if a twenty-inch focus lens were used under such circumstances that with an aperture of one inch or *f*-20, the diffusion were one-fortieth of an inch, the substitution of a five-inch lens and *f*-5, or one-inch aperture, would give $\frac{1}{40}$ approximately.

This, however, does not cover the question involved. It does not necessarily follow that the smaller lens would give four times the depth of focus of the larger; dissimilar images cannot be compared by the circle of confusion alone; it cannot be assumed that this should be the same in a quarter-plate as in a 15 × 12 of the same view. A diffusion of outline that would only give softness in the larger picture would be sufficient to entirely destroy the character of the finer details in the smaller, as every detail in one is four times larger than in the other. If the mast of a yacht, for example, measured one-sixteenth of an inch, one-fortieth of an inch diffusion would be very different from the same amount in an image that was one sixty-fourth only. This would not be the same depth of focus; in order to produce the same effect the departure from actual sharpness should be proportionate to the size of the images.

This is strongly supported by assuming two negatives to be taken of a certain view, one with a twenty-inch focus lens, and the other with a five-inch, the latter being then enlarged four diameters. If the same circle of confusion were allowed in each negative the enlargement would

show four times as much "fuzziness" as the direct print in any part that was out of focus, and it could not possibly be contended that the two lenses had given equal depth. If, however, the diffusion in the larger negative were four times that in the smaller, the enlargement and the large direct print would be absolutely identical in sharpness, and this should be called the same depth of focus. *To produce this result the aperture would measure exactly the same with each lens*, which would support my original statement.

In my paper it was considered best to give the most simple illustration of this principle, in fact, the only one that could readily be seen by comparing the circles of confusion alone.

In the portion published in your issue of February 19, there is a slight printer's error in the last paragraph: *one-fourteenth of the focus* should read *one-fortieth*.—Yours, &c., HENRY W. BENNETT.

To the EDITOR.

SIR,—I have read an article in your JOURNAL of March 11, 1892, signed Henry W. Bennett, on photographic lenses, in which it is assumed that depth of focus depends on the actual size of the stop, and is not influenced by the focus of the lens.

Mr. Bennett says that this proposition is somewhat startling to most photographers, and I confess that it has also startled me, because I think it is contrary to mathematical principles, and also to what Mr. Dallmeyer says on the depth of focus in his short treatise on photographic lenses.

If two lenses have the same diameter, or if you make use of the same stop, and the focal length of one lens is the double of the focal length of the other, an object, viewed, of course, at the same distance, will not be equally defined, if the object is nearer than the plane, beyond which all objects will be sharp, because this plane will not be situated for both lenses at the same distance. It will be about half the distance for the object lens with the shorter focus. If two lenses have an aperture of the same value, the depth of focus does not vary in inverse proportion to the focus of the lens but as the square, consequently a sixteen-inch lens will possess, not half, as Mr. Bennett says, but only quarter of the depth of an eight-inch lens, if *f*-16 were the stop used in each.

I hope you will agree with what I take the liberty of writing to you.—I am, yours, &c., BARON ALBERT DE ROTHSCHILD.

Vienna, Austria, March 17, 1892.

MISLEADING PHOTOGRAPHS.

To the EDITOR.

SIR,—I notice in the "Answers to Correspondents" column in your last issue an inquiry by "Solicitor," as to some misleading photographs which are about to be produced by an opponent in a lawsuit respecting the value of an estate. Allow me to suggest that he should have some stereoscopic views taken, as these, when viewed in a stereoscope with lenses of the same focal length as those used in the camera, must represent the view exactly as seen in nature.

I have often wondered why stereoscopic photography is not universally adopted in legal and criminal cases.—I am, yours, &c.,

Bryn Coed, Crescent-road, Chingford, March 19, 1892. T. HORNE REDWOOD.

THE ENFIELD CAMERA CLUB DISSOLVED.

To the EDITOR.

SIR,—Referring to my previous circular, I have to inform you that at the meeting held on the 10th inst. it was resolved:—1. To dissolve the Enfield Camera Club. 2. To leave the Committee to realise the property of the Club and apportion the result to members at their earliest convenience. The above resolutions speak for themselves, and I send you same with much regret. You will hear from me when the latter resolution has been carried into effect. Meantime, I am, yours, &c.,

JAS. DUDIN, *Hon. Secretary.*

Enfield Camera Club, Roseneath, Chase Green-avenue, Enfield, March 19, 1892.

P.S.—Those members who joined quite recently and paid their subscriptions and entrance fee will, of course, have same returned.

CORRECT EXPOSURE AND THE SPEED OF PLATES.

To the EDITOR.

SIR,—In my *Index of Exposure* I have hitherto given a speed table of plates compiled on information supplied by the plate-maker in each case and based on sensitometer numbers. The public have by this time gradually, but surely, confirmed the opinion expressed in the first edition, that sensitometer numbers are hopelessly and entirely unreliable.

This being so, I propose, in the forthcoming edition, to omit the plate tables in the form in which they have hitherto appeared, and substitute what I will call an experience table, compiled from the actual experience of users of the plates, in place of the manufacturers' quotations based on sensitometer number, or, as in many cases, on mere guesswork, in which the "wish" to have a high-speed representation has been "father to the thought," when quoting for publication in a list intended to show correct speeds, but to a large extent inaccurate, because regarded as comparative and competitive.

To enable me to prepare this experience table, I ask your kind assistance in placing my request for information before your readers, and I shall be greatly indebted to all such if they will oblige by sending me, through the post, to Sutton, Surrey, *an early reply* to the following questions:—

1. What plates do you use?

2. What "No. of Times" have you found them to be, on the basis of Wormald's tables for thirty-times plates?

By kindly complying with this request they will render public service, in helping to a better knowledge of correct exposure, without which the pursuit of photography has so frequently been found uncertain and disappointing.—I am, yours, &c., A. R. WORMALD.

Sutton, Surrey, March 21, 1892.

P.S.—The new table will only give collated results; in no case will the name of any correspondent be printed.

'THE LEGAL SIDE OF PHOTOGRAPHY.'

To the EDITOR.

SIR,—As adding to the practical value of the lecture under the above title, reported in the valuable columns of your last issue, permit me to say that the lecturer, Mr. Watson Brown, B.A., LL.B., is himself a practising solicitor. May I add that the directorate of the Leytonstone Camera Club have been highly complimented upon their lectures and their lecturers, the latter being all members? We are a young club, not yet nine months' old, but are happy in the possession of several professional experts. I make these remarks with the only object of inviting visitors to the weekly Wednesday evenings at the Leytonstone Assembly Rooms. I shall be happy to send a syllabus to any gentleman who cares to put himself into communication with me.—I am, yours, &c.,

ROBERT OVERTON, (*Joint*) *Hon. Secretary.*

'*Our Camera Club*,' *Leytonstone, March* 21, 1892.

BORROWED PLUMES.

To the EDITOR.

SIR,—Could you give me the address of a firm that would supply me with specimens? I am in rather an awkward position, as the firm I have recently left did their own printing, and I do not at present know a firm that would supply me with specimens. Of course, I should want them unmounted and decent, and am willing to give a fair price. I would guarantee, if necessary, that they should all be destroyed within a month of my opening the business, as I do not wish to injure the trade by good specimens and inferior work. I have enclosed a stamped, directed envelope.—I am, yours, &c., SPECIMEN.

[We have substituted a *nom de plume* for our correspondent's real name. Æsop tells us of an unlovely fowl that strutted about in the borrowed plumage of a more beautiful bird, and thereby encountered a melancholy fate. We had hoped that this disreputable traffic in specimens among photographers just commencing had entirely ceased. —ED.]

Exchange Column.

**** No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Wanted, 7×5 carryscope, in exchange for a Dallmeyer 1 a C.-D.-V. lens.—Address, [illegible], Photographer, Coventry.

Will exchange Rouston Humber tandem tricycle, in good condition, for good half-plate camera, lens, and stand complete.—Address, F. H., 29, Russell-road, London, W.

Will exchange a whole-plate, long-extension camera, rapid rectilinear lens, and three-fold tripod, for Safety bicycle of good maker.—Address, GOAD, 38 Rainbow-street, Camberwell, S.E.

Wanted, cabinet portrait lens, by good maker, in exchange for telescope on table stand, with terrestrial and celestial eyepieces, &c., fitted in cabinet.—Address, R. S., 12, Park-road, Blackburn.

A quarter-plate camera, double extension, and all improvements, with six double dark slides, with leather case, in exchange for a wide-angle rapid rectilinear lens by good maker.—Address, EDWARD HUGHES, 2, Trafalgar-terrace, Bray, Ireland.

Splendid whole-plate camera, tripod, and five double dark slides; will exchange for Safety bicycle, American organ, or half-plate camera, with cash adjustment. Also a powerful, whole-plate burnisher, with gear; will exchange for a half-plate rolling press.—Address, GARSON, Chelmsford.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," *2, York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

John Rowley, Eccles.—*Portrait of Nellie Wood, age* 100.

T. Protheroe, Bristol.—*Photograph from an Oil Painting of Right Hon. W. E. Gladstone.*

W. H. C.—Inquire of Hampton, Judd, & Co., Farringdon-road, E.C.

GEORGE SCHULTZ.—Dr. Maddox's address is Greenbank, Park-road, Portswood, Southampton.

H. J. CHANNON.—The length of your letter has compelled us to hold it over until next week. Thanks.

T. P. COLLINGS & Co.—At p. 147 of the ALMANAC for 1875 will be found instructions for printing on wood by the "blue" process.

D. J. O'NEILL.—The address of the author is East India-road, E. We have no further information than that contained in the paper.

W. HILL.—Particulars of working the wet-collodion process may be obtained from any old treatise on photography, such as Hardwich's *Manual*.

BOND.—We are unable to give you the names of manufacturers—not wholesale dealers, who do not make—of trays, mats, preservers, and ferrotype plates for the wet-plate process, either English or German.

R. C. C.—Water that has been boiled for half an hour or so, preferably in an old kettle, and allowed to cool, will do quite well for dissolving oxalate of potash. A slight precipitate, if any, of oxalate of lime may be disregarded.

R. FULLER.—All the different companies that have been formed to take "photographs in natural colours" have, as a matter of course, "come to grief," and so, to an extent, have those who, unfortunately for them, invested money in the concerns.

RALPH complains that he cannot get crayons to take on bromide paper, because there is so much glaze. He asks how the surface is prepared?—If the print be rubbed over with finely sifted pumice or cuttlefish powder, it will give a tooth that will take the crayon freely.

JOS. SPA.—So far as we can judge from the print sent you have been far too lavish in the use of the lubricant; also, we fancy that the roller of the burnisher must be a little hollow, as the pressure on the middle of the picture does not seem equal to that at the sides.

J. BURLEY asks: "Can you give me any rule, &c., to guide me as to the correct distance the two lenses should be apart in a rectilinear or euryscope? Have opticians any particular method, or is it arrived at by 'trial and error!'"—There is no method but that of trial and error.

Y. G.—If the silver stains caused by printing from the negatives before they were dry cannot be removed by a weak solution of cyanide of potassium, we fear they are ruined. The formula for Farmer's reducer is: Ferricyanide of potassium, six grains; hyposulphite of soda, one drachm; to water, eight ounces.

BIRT ACRES.—The view you take of our remarks may be excusable, but we cannot quite admit that it is the correct one. We had no desire that you should interpret our concluding sentences in so markedly a personal sense. As we can see no possible good in prolonging the controversy, we do not publish your letter.

S. J. E. complains that he cannot get the chloride of silver, precipitated with common salt, to settle down from the washing waters from prints prior to toning, and seeks assistance. If a small quantity of nitric acid be poured in, and the whole vigorously stirred for a few minutes, the chloride will subside in a few hours.

D. J. S.—The plate, so far as we can judge, is insoluble. Why, we cannot say. It will be quite impossible for you to get anything like a satisfactory collotype plate with the primitive drying arrangements you are using. Collotype is a process that wants considerable study and practice before it can be worked satisfactorily, and that can only be done with suitable appliances.

A. STOKES wishes to know if all the detective cameras sold by the different dealers are patented, and, if so, whether he would be allowed to make one for his own use, but not for sale.—Some of the cameras are patented, and some are not. Our correspondent can make any of the latter for his own use or for sale; but, with regard to the former, he must obtain a licence from the patentee, even for one for his own use.

DISAPPOINTED.—The queries are so ambiguous that we scarcely know how to reply. A patentee has a protection in his patent, and no one else has a right to manufacture or use the invention. If any one infringes the patent, the owner can recover damages and obtain an injunction restraining further infringement; but the patentee will have to substantiate his patent by showing that the invention is new, and that he is the inventor, and, therefore, entitled to obtain a patent for it.

G. J. J. asks: "1. If any special restrictions are put upon tourists visiting Rome or Naples as regards taking photographs of public buildings, &c.? 2. Can you recommend films instead of plates for such work?"—1. Perhaps some of our readers who have photographed at Rome or Naples can answer the question. 2. Yes, other things being equal.

METROPOLITAN says: "I am a stationer, and, two years ago, took up selling photographic apparatus and chemicals. Amongst the latter are bichloride of mercury, cyanide of potassium, and the usual things used by photographers. A neighbour of mine, a chemist, seems annoyed at this, and has told some persons that I am infringing the law, and that he could, if he chose, stop me, as well as have me mulct in heavy penalties." He wishes to know if this is not "idle bounce?"—Certainly not. Under the Poisons Act any one but a certified chemist is prohibited from retailing poisons which are named in the schedule, amongst which are those mentioned, and then only under certain conditions, such as in the presence of a witness, entering the name of the purchaser in a book kept for the purpose, and attested by him. Any one infringing this law, which is very stringent, renders himself liable to very heavy penalties.

NEMO writes: "Some time back I developed a negative of a church, with the result that the spire and weathercock obtained too much density to print through. I locally reduced this, and so the spire, &c., prints through all right; but in the reducing operation the sky parts surrounding got reduced also, so as to print through in patches. I got over this by blocking out with Bates's black varnish. Now, if I varnish the negatives in the ordinary way, the varnish will dissolve Bates's black, and thereby render useless all my careful work in blocking out the spire. Is there any varnish that can be procured that will not dissolve Bates's, or you, perhaps, might know of some method whereby it might be overcome?"—We do not know the composition of Bates's varnish; therefore, cannot say what varnish will not disturb it. However, we should surmise that ordinary negative varnish, if the plate is not made too hot, would not do so. If a trial proves that it does so, then it can be protected by coating the film with a thin solution of gelatine before applying the varnish. On the whole, it may be less trouble to clean off the present "blocking out," then varnish the negative, and block out again with the black.

PHOTOGRAPHIC CLUB.—March 30, Smoking Concert. April 6, Dark-room Appliances; paper by Dr. Jeserich on *Photography as Applied to the Detection of Crime.*

ON Wednesday evening next, Mr. Gambier Bolton lectures at the Birkbeck on *Wild Animals in Captivity*, illustrated by photographs. The Secretary of the Institution will supply tickets.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—March 31, *Photography on Wood*, demonstration by Mr. W. J. Rawlings. April 7, *Collodio-bromide Emulsions*, by Mr. Alexander Mackie. April 14, Adjourned Discussion on *The Wet-collodion Process.* Visitors are welcomed.

CROYDON MICROSCOPICAL AND NATURAL HISTORY CLUB (PHOTOGRAPHIC SECTION).—Fixtures for April: 1, *Cresco-Fylma*, by Mr. A. J. E. Hill. 8, *An Improved Platinum Paper*, and *Printing by Artificial Light*, by Mr. J. W. Smith. 9, Half-day Excursion. 22, *Films.* 23, Half-day Excursion. 29, *Amateur Plate-making*, by Mr. A. S. Wild.

A ROYAL RECOGNITION.—Some time since we recorded the fact of Her Imperial Highness the Archduchess Stephanie of Austria having expressed a desire to possess one of Mr. Dresser's pictures which was on view at Vienna last year. The picture was of course duly forwarded to Her Imperial Highness, who, in return, has lately made Mr. Dresser a present of a beautiful gold pin set in rubies and diamonds, having her own monogram and the Austrian crown on the top.

AMONG the lecturers at the Royal Institution after Easter will be Mr. Frederick E. Ives, with two lectures on *Photography in the Colours of Nature* The Friday evening meetings will be resumed on April 29, when a discourse will be given by Dr. William Huggins, on *The New Star in Auriga*; and succeeding discourses will probably be given by Captain Abney, Dr. B. W. Richardson, Mr. J. Wilson Swan, Sir James Crichton-Browne, Mr. Ludwig Mond, Professor Dewar, and other gentlemen.

MR. HUME, of Edinburgh, is shipping to China a "Cantilever" enlarging apparatus, with thirteen-inch aperture condenser, to cover fully an 8×10 plate. It is an instrument of the highest finish, in the "Indian pattern," brass-bound, on gun-metal feet, sliding on rails six feet long. The brass draw-tubes are very massive and rigid, being one and a half inches in diameter and four feet long. The movements of the relative parts provide for the making of pictures from one to ten diameters of the 10×8 plate. It will thus make enlargements up to eight feet.

CONTENTS.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1665. Vol. XXXIX.—APRIL 1, 1892.

THE USE OF FOCUSSING EYEPIECES.

Our title comprehends a broad field of subjects, but we more particularly desire to restrict it to optical combinations for ordinary every-day work in studio, or field portraiture, or landscape. Something might be said of the microscope as used for the purpose in photo-micrography, or the small lens employed by the optician in lieu of any "ground glass" in testing the capabilities of his various lenses; but we would leave such branches of the topic for dilating upon at some future period, as, instructive though a discussion upon them would be, it could not be comprised within the limits of a single article. We were led to the belief that some remarks about eyepieces would not be misplaced by a little incident that occurred within our own ken.

Some years ago, when photographing in company with a gentleman who had had much experience, we found him toiling, we might almost say, in the endeavour to get a sharp focus of a difficult subject. We offered him the loan of a focusser we had at hand, and he, smilingly, said he had no need for any such aid, but still, out of politeness, made use of the proffered assistance. Lately, however, in conversation with him, we found not only that he now invariably focussed with such optical aid, but he was very *exigeant* as to the particular form of instrument employed.

And so we believe—nay, we know—the case stands with many. Some decline the use of a focusser under the idea that it is unprofessional and amateurish, others are afraid they will be bantered as having poor eyesight; and it is our experience that when a man really does begin to feel the need for a pair of spectacles, but can just manage without, that is the time he is most insistent upon the fact that his eyes are as good as ever.

Finally, there is still another class who have no knowledge of a focussing magnifier except through the optician's price-lists. Of course, for outdoor work it increases, though by a very small amount, the weight of the kit, but we do not hesitate to say that where accurate focussing, especially with large angular apertures, is desired, the use of such an instrument is invaluable, whether it be a home-made one, constructed of a pill-box and a spectacle lens or a thoroughly convenient and specially devised one, as sold by the lens-manufacturers for the particular purpose. Naturally, much depends upon the eyesight of the photographer as to the extent of its usefulness, but, to the best eyes, there are times when some things could not be satisfactorily and quickly done without employing it. For example, we have met a gentleman whose eyesight was so acute that he could read, aloud and quickly, matter printed in Snellen's smallest test-types at a distance just under five feet, which is equivalent to saying he could see objects with a facility equal to that enjoyed by an average reader armed with a glass magnifying four diameters. This, however, is a very exceptional case, and the greatest value of the focusser is felt by those whose eyesight is as good as ever for objects more than about half a yard away, but inefficient within that distance. If they wear glasses, this particular evil is by them corrected; but there is a large body who, in ordinary cases, would receive benefit from its common use, and a still larger body by its occasional use.

It is not necessary to have an elaborate or a costly instrument. The most simple is a spectacle lens of deep curves, fitted at the end of a pill-box. Some who carry a small magnifier in their pocket find it convenient to use it; but the employment of this kind of lens is greatly facilitated by having a portable foot or case for holding it at a constant distance from the ground glass; in fact, the real value of the focusser is not felt unless some such provision be made. A common three-legged seed microscope is often used; but it is always better for the foot or tube used to keep the lens at a constant distance to be opaque, and thus prevent the part to be magnified from receiving any extraneous light. This, indeed, is one of the recommendations of the instrument. Of the better class of magnifiers, the most common is a Ramsden eyepiece, fitted with a screw for adjusting the distance from the focussing screen for any eyesight. There is also fitted with this pattern a screw-collar, or other contrivance, for clamping the lens *in situ* when once the focus has been duly set. Some of the objections to the employment of the instrument have arisen through one person attempting to make use of a glass set for one eyesight and not adapted, perhaps, to that of the objector. The great advantage of this particular form is the large field of view it permits and the perfect flatness of the whole of the field.

We have seen one, and one only, of this make modified in what we consider a very advantageous manner. The photographer who used it in his studio had found that the constant use of the metal upon his focussing screen had dimmed its surface by a multitude of fine scratches. He fitted a new screen, and had adapted to his Ramsden a flange, covered with velvet, and this was an improvement in many ways. As to the actual mode of employment, that is almost self-evident; but it may be pointed out that, to get its full value, the screen should be of very fine glass—etched, not ground—rendered still further transparent, in the usual manner, by oiling the surface. Then, again, it may be said that when examining very dimly illuminated objects the magnifier is best placed, not flat against the glass, but at an angle, pointed, in fact, in the direction of

the centre of the lens. We need add no more after saying that, by the use of a focussing magnifier, time is saved, and convenience consulted to an extent that is not dreamt of by those who ignore, and, as is often the case, almost deride its employment.

ADVANCES IN KALLITYPE PRINTING.

Almost contemporaneous with the publication of the fact that Mr. W. Willis has succeeded in devising a platinum printing process, having the image-forming compound on the surface of the support, and developable at ordinary temperatures, to which it is said that certain refinements in the quality of the pictures will be joined, we are in possession of details of some improvements recently effected in the kallitype process, which, from the point of view of simplicity of working, we are disposed to consider as advances. In order to appreciate the nature of the improvements, it may be necessary briefly to recite the stages through which kallitype printing has passed.

The first process, called Kallitype, No. I, consisted in the main of coating paper with a ferric compound, exposing to light in the usual way, and developing the ferrous image by means of a solution containing silver nitrate and a soluble salt of an alkali metal or ammonium—such, for example, as potassium oxalate—and ammonia. The prints were then washed in a solution of soluble citrate or ammonia. This process, however, has, we believe, been abandoned in favour of that called Kallitype, No. 2. In this a mixture of ferric oxalate and silver nitrate is applied to the paper, and the picture is developed in a bath containing Rochelle salt and borax, the washing solution consisting of ammonia and water. It will thus be perceived that in the second process the silver is applied direct to the paper before exposure, instead of, as in the older method, being made a constituent of the developing bath.

Two modifications of the process are now published, each having distinctive features of its own, which assures us that the possibilities of this system of printing are not much more than in their initial stages of realisation. In the first of these the sensitising solution consists of ferric citrate, oxalic acid, and silver nitrate, and the prints after exposure are developed by means of ammonia and citrate of soda; that is to say, without the employment of a "developer" *per se*, a final washing in dilute ammonia being, of course, necessary. In the second modification, however, not only is a developing solution *per se* rendered unnecessary, but development itself is obviated. This is achieved by coating the paper with a mixture of ferric oxalate, potassium oxalate, and silver nitrate. Paper so sensitised prints out in the frame—a result due presumably to the presence of the potassium oxalate, and the pictures are washed in citrate of soda and citric acid, and finally in ammonia, as heretofore.

Assuming the last-mentioned process to be perfected for commercial purposes, kallitype will offer the advantages of supplying both a developing and a printing-out process. Of the comparative merits or demerits of the two methods we do not seek occasion to speak at present, but it may be permissible to submit that probably the larger number of modern amateurs prefer those systems of printing which produce the image without the need of development—a fact to be considered in noting the vitality of the much-condemned and attacked albumen process.

Kallitype is the only silver printing process extant which does not entail the use of hypo as a fixing agent—which, taken in conjunction with the variety of ways in which the image may be produced, disposes us to believe that it has secured a permanent place among modern printing processes. Of its artistic capabilities we have spoken before in a favourable strain, while as for the probable "permanence" of the results we think there is little to be feared on that score.

Death of Mr. A. Vandyke, of Liverpool. — We are sorry to learn of the death of this eminent Liverpool photographer, an event which took place yesterday (Thursday) morning, at half-past one, after an illness of only three days. Mr. Vandyke, who was some years since a partner of the firm Vandyke & Brown, made a speciality of large direct portrait work, and for this class of portraiture received a medal at the last great International Photographic Exhibition in Liverpool.

The Price of Silver.—On Tuesday last bar silver was quoted on the Exchange at 39*d.* per ounce, this, of course, producing a corresponding fall in the price of the nitrate, which will, doubtless, be welcome to the dry-plate makers, enabling many of them to augment the scanty profits of which complaint is often heard. As it is thought that the price of the metal has reached its lowest point, we may suppose that large stocks of nitrate will be bought by the various industries employing it, among which, by the way, photography does not by any means occupy the leading position.

"Snap-shotting" in the Antipodes.—The enthusiastic amateur with the hand camera is, apparently, not confined to this side of the globe. In the account of the removal of the man Deeming, who is suspected of several murders, from the court at Perth (Western Australia), an amateur, with a hand camera, attempted to obtain an instantaneous photograph of him. The prisoner, observing what was being attempted, resented, as he had done being sketched in court, and, as the *Standard* has it, "it was with some difficulty that he was restrained by the police from 'going for' the enterprising amateur." In this country, it is a little surprising that enthusiastic "snap-shottists" have not been "gone for" more frequently than they have been, seeing the objectionable manner in which some amateurs use their detective cameras. *Verb. sap.*

The New Methylated Spirit.—Despite the many protests which have been uttered as to the action of the Excise in ordering the addition of mineral naphtha to methylated spirit, and its assumed unsuitability for emulsion work and other photographic processes, we have so far had little, if any, published experiences of those who have tried it in lieu of the old kind. It is, therefore, interesting to know that at least one experimentalist has been working with it, and still more surprising to find that the results of his attempts to use it were far from that unsatisfactory nature which might have been anticipated. At a meeting of the London and Provincial Photographic Association the other night Mr. W. E. Debenham showed a collodio-bromide transparency made by the aid of the new spirit, which, he stated, he found did not hurt the emulsion at all. It would be just as interesting to know whether the spirit would be equally innocuous in the case of gelatine emulsion.

Sel d'Or.—In connexion with the above subject, modern photographers often confound the old *sel d'or* toning bath with that of the hyposulphite of soda and gold compound toning and fixing bath. This was the case at the meeting the other night. The latter bath was made by adding the chloride of gold, in solution, to a strong solution of hyposulphite of soda. The prints, when immersed in this, toned and fixed at the same time—often a matter of several hours. *Sel d'or* is a double salt of hyposulphite of gold and soda, and forms needle-like crystals. It used to be sold in small bottles containing fifteen grains each, as the chloride of gold now is; but the price was much higher, about four shillings for that quantity. An acidified solution of this salt formed the toning bath, and the prints were

afterwards fixed in a plain solution of hyposulphite of soda. The principal use of this salt was, however, for gilding Daguerreotypes. though it was also used for toning plain salted paper prints. With albumen prints it did not answer, as it had a tendency to make the lights yellow. From this it will be seen that the two methods of toning were widely different.

Orthochromatic Effects.—Divers opinions are often expressed as to whether plates, prepared with eosine, render any orthochromatic effect without a yellow screen. Some have averred that they do, while the thing is as strongly denied by others. Possibly the lenses used in the experiments may, in a measure, account for the discrepancies. We are led to this remark from being recently shown a lens with two cemented surfaces, which, when placed on white paper, was decidedly yellow, though the glasses themselves, we were assured, were quite colourless. The Canada balsam, used in cementing, was the cause of the yellowness. If a lens of this kind were used in one set of experiments, and one free from colour in another, it is quite conceivable that the results would not be in accord, inasmuch as practically a yellow screen had been employed in one case and not in the other. With some old lenses, not only has the balsam become yellow, but the glass also; indeed, the latter was so tinted in the first instance. Now, working with a lens of this description becomes equivalent to using a faint yellow screen. Opticians are now able to obtain glass free from colour, and it will be obvious that lenses made with it will show orthochromatised plates to a disadvantage as compared with lenses of yellow glass and discoloured balsam.

Old Silver Prints.—The exhibition of silver prints made thirty years and upwards ago, now open in the rooms of the Photographic Society, is, numerically, by no means a large one. But it is an exceedingly interesting as well as instructive one. All modern photographers should take the opportunity to see the collection, as they will see the class of work produced when the art might almost be said to be in a primitive state. At the period that most of the negatives were taken the only lenses in use were the single lens and the Petzval portrait combination. Retouching the negative was a thing unheard of. There were no dry plates except those that required many minutes' exposure in a good light, and all negatives were by the wet-collodion process. Furthermore, the alkaline gold toning process was not then introduced. Yet, as the Chairman remarked at the meeting last week, with regard to the pictures, nothing much better was produced at the present time, either as negatives, ortho or isochromatic effects, artistic compositions, or production of an optical tool. An idea seems to prevail at the present time that silver prints must necessarily fade in a year or two, yet there are prints shown that are thirty-seven years old which indicate very little, if any, signs of decay. There are a series of prints a couple of years younger, some of which are in a good state of preservation notwithstanding that about twenty years of their life were spent in parcels as lumber in damp attics. The mounts show that they have been covered with mildew, yet the pictures, though in some instances yellow, show no loss of detail. In face of these examples, who will say that silver prints cannot be made permanent? This exhibition will remain open till April 12.

Thermo-dynamical View of the Action of Light on Silver Chloride.—Speaking to this subject at a recent meeting of the Physical Society, Mr. H. M. Elder said that "in the decomposition of silver chloride by light chlorine was given off, and a coloured solid body of unknown composition (sometimes called 'photochloride') formed, the reaction being indicated by the formula $nAgCl = Ag_nCl_n - 1 + \frac{1}{2}Cl_2$. If the experiment be carried out in a sealed vacuum, the chloride is darkened up to a certain point, but regains whiteness when left in the dark. These facts have led him to believe that the pressure of the liberated chlorine is the function of the illumination or intensity of light falling upon the chloride, in the same way as the pressure of a saturated vapour is a function of the temperature. Since illumination is a quantity in many respects analogous to temperature, he considers it not unreasonable to apply thermo-dynamic arguments, and regard rine, in presence of silver chloride and 'photo-chloride,' 'be working substance in a 'light engine.' He therefore supposes a Carnot's cycle to be performed on the substances at constant temperature, the variable being pressure, volume, and illumination. Since the cycle is strictly analogous to Carnot's, except that illumination is written for temperature, he infers that the efficiency is a function of the two illuminations. It also follows that, just as Carnot's cycle is used to determine an absolute scale of temperature, so this cycle may be applied to determine an absolute scale of illumination. It only remains to determine an empiric scale analogous to the air thermometer, and to compare it with the photo-dynamic scale, provided a method of making the comparison can be devised."

Life Size—what is it?—In the paradoxical paper by Mr. H. P. Robinson, read at the Photographic Conference last week, one of the points raised practically was, whether we should have scientific truth, artistic truth, or lies in photography. Some commercial photographers would answer by saying, "You pays your money, and you takes your choice. We will supply what you desire, only tell us what you want." This is pretty well expressed in the communication, and brings us to a practical point that comes before portraitists every day. What is life size? The obvious answer is, the size of life, and that is correct; but will it appear to be so in the picture, that is the point? It can, with equal truth, be answered both negatively and positively, inasmuch as the picture may seem the size of life, or either larger or smaller, according to circumstances, although the actual dimensions are the same in all the cases. For example, if two portraits be enlarged, the one, say, of a gentleman with round features, and but little hair on the head, and a small beard; the other just the reverse—long features, with beard and a good amount of hair on the head, both of the exact size, by measurement, of the prototypes, the enlargements in this case should include a good amount of the figures—say, made on paper forty-five inches by thirty-five. If these two pictures be framed the full size, and hung pretty high in a room, the one will look much smaller than life size, the other but little so. If, instead of being framed the full size, they are cut down to twenty-four inches by eighteen, the small-featured one will seem nearly life size, and the other but little over. Now, if the pictures be still further cut down—for example, the heads only framed behind fifteen by twelve inch mounts—and be hung on a level with the eye, both will seem larger than life size, that with the long features and full beard appearing to be of really Brobdignagian proportions. What shall we go by? actual measurement or apparent accuracy in everyday work?

VARIATIONS IN COLLODION EMULSION WORKING.

All who have worked with collodion emulsions must have experienced, at one time or another, their vagaries arising from different samples of pyroxyline and various other causes, perhaps at the moment wholly inexplicable, and for that reason all the more annoying. In the case of washed emulsions, it frequently happens that, although in its first stage, that is, before pouring out to set, it was as nearly perfect as might be. After the operation of removing the soluble salts has been performed, it is found to have lost all power of giving density, sometimes even under silver intensification. With some samples of pyroxyline, this will be invariably the case, for the simple reason that the cotton is entirely unsuited to the process, but it will occur occasionally even with samples that are known as a rule to work satisfactorily.

Again, in the case of an unwashed emulsion, it is not unusual to obtain a somewhat similar result, more especially when the collodion is sensitised very shortly after bromising. Here, too, the fault may be laid to the pyroxyline, for while some kinds, chiefly of the so-called "high-temperature" class, but by no means invariably so, will admit of the collodion being made, bromised, and sensitised straight away in one operation, the majority, if they do not absolutely require it,

are, at any rate, better for being allowed to "ripen" for some days, or a few weeks, between bromising and sensitising. In many instances the utility of this aging or ripening is so great, that a collodion that is utterly useless when freshly made will, in the course of three weeks or a month, give the most perfect results possible, and this is especially the case when a large proportion of cadmium salt is employed in bromising.

Whatever the cause may be, the result is sufficiently annoying, for it is anything but satisfactory to have a quantity of emulsion on hand that is absolutely useless and represents so much material wasted. Emulsions of this character seldom or never—practically never—improve by keeping, as does the unsensitised collodion, but retain their bad qualities to the last; whereas one that is slightly foggy when newly made will often be found to work perfectly satisfactorily after a short time. It is therefore of no use to keep the emulsion on the chance of its improving, and means have to be sought by which it can be brought into a proper state. Fortunately, these are easily available at the cost of a little more labour and material, which is better than losing the whole batch of emulsion.

In the case of an unwashed emulsion that refuses to give density, if the cause be simply the want of ripening, it is only necessary to add to it, say, an equal quantity of the same bromised collodion, and set it aside for a few weeks, when, on the addition of the requisite quantity of silver nitrate to sensitise the newly added collodion, the result will, in most cases, be an emulsion as good as, or perhaps a little better, than if the sensitising had been performed in one operation with the same interval after bromising. The prolonged contact of the silver bromide, first formed with a large excess of soluble bromide, conduces to a finer and better character of the image, and this method of sensitising in two operations, with a wide interval between, is one that has long been recognised as a good one.

If the want of density occur with a collodion that has had time to ripen, it is still a proof of the unsuitability of the pyroxyline, but the same remedy as in the last case is obviously not available. The cause is, no doubt, the want of a sufficiently powerful organic reaction between the pyroxyline and the silver, when, as happens in the great majority of cases, the soluble bromide is in excesss during the whole of the period of sensitising. To remedy this it generally suffices to over-sensitise a portion of the collodion, allowing it to stand in the presence of excess of silver for a few hours, and then to add a sufficient quantity of the same bromised collodion, to leave the soluble bromide just slightly in excess. For instance, in preparing five ounces of emulsion, let four ounces of collodion be sensitised with silver sufficient for five ounces, and after the lapse of a few hours—not, at the utmost, more than twenty-four—let the remaining ounce of collodion be added. In the case of an emulsion that has already been fully sensitised, and found to be wanting in vigour, add sufficient silver for a definite quantity of collodion, which can then be added after the necessary interval of time. In either of these cases it will be found safer to make a further addition of a small quantity of either citric or nitric acid, in order to guard against fog—one grain of the former, or half a minim of the latter, to each ounce of emulsion.

In "doctoring" an imperfect emulsion under such circumstances there is no actual loss, except, perhaps, of the time occupied in the task; but with a washed emulsion the case is different, since it will be invariably necessary to re-wash it after the remedial treatment if it is to be again used as a washed emulsion, and in any case, even if subsequently employed as an unwashed preparation, the first batch of solvents are lost. In this case, supposing the pyroxyline in the first case to be suitable, the result is due to the removal of the organic silver element through improper treatment in washing, and if such only be the cause it will usually be sufficient to add a fresh quantity of bromised collodion, and to re-sensitise with the proportion of silver necessary for the added quantity. If, however, the pyroxyline be unsuitable for washing, the defective emulsion can only be utilised by re-sensitising it as an unwashed emulsion, as, even if mixed with the most perfect collodion possible for the purpose, it would only, in re-washing, lower the quality of the latter, if indeed it did not reduce it to its own level.

There is one other way in which such an emulsion may be usefully employed, and that is in modifying the structural character of another. It very often happens, especially in the case of unwashed emulsion, that the only fault to be found is in the structural character, a "crapy" or, perhaps, a "mottled" appearance of the film marring an otherwise perfect image. As a rule such qualities are accompanied by a ready tendency to give any amount of vigour or density under development, while the structural characteristics that accompany the want of density of an over-washed emulsion are the very reverse of those above mentioned, and the two preparations may often be mixed with the most satisfactory results, and to their mutual improvement.

But defective emulsions, whether washed or unwashed, whether merely wanting in density or badly fogged, may be utilised in an entirely different manner, and with advantages that do not attach to the methods already given. The plan we are about to describe partakes of the character of a cross between the wet and emulsion processes, and, while possessing certain features of each, is free from the principal troubles and difficulties of both. The wet process, as is well known, is still largely used for some purposes, but chiefly for negatives for "process" work and for lantern slides, and, especially for the latter purpose, would, no doubt, be still more generally employed if it were not for the trouble involved in the management of the bath. Again, many who at the present time use the wet-collodion process on account of the quality of result obtained would gladly substitute an emulsion if only the same rapidity of working could be combined with the quality of wet collodion, even if the emulsion had to be employed in the wet state. The modifications we are about to describe will, we think, fulfill the requirements.

Briefly stated, the method consists in using the emulsion, after it has been suitably treated to relieve it of its defects and faults, as a partially sensitised collodion, treating it with a solution of silver, which does not necessitate the nicely balanced conditions essential in the ordinary silver bath, and developing either by the acid-silver or alkaline methods as may be preferred, though, of course, a variation in the method of working will be necessary in the two cases. From personal use of this process, we can recommend it as something more than a mere makeshift method of saving a spoilt emulsion, for it actually constitutes an easy means of securing all the advantages of collodion without the trouble and anxiety that undoubtedly attend the use of the bath, especially if not kept in order by regular use.

After all, in adopting such a measure we are only reverting to the principle recommended many years ago as a decided gain by whom we forget at the moment—of partially sensitising the collodion by the addition of a few drops of silver solution. In that case, however, the quantity of silver added to the collodion was relatively minute, being little more than as much as the soluble haloids in the collodion would take up and dissolve; in fact, the idea was to saturate the collodion with silver in the same way as the bath. The result was claimed to be a decided gain in sensitiveness, as well, if we remember rightly, as other advantages.

As to the practicability or utility of collodion emulsion used wet, there can be no doubt, though, as generally used—with an alkaline or other organifier and alkaline development—the results have scarcely been found to equal those obtainable with wet collodion and the bath. But the modified conditions under which we propose to work place the process upon an entirely different footing. The late Thomas Sutton, it will be remembered by our older readers, published a number of experiments in connexion with plain bromide of silver films, both in the form of wet and emulsion plates, and with iron and silver, as well as alkaline, development; and the results he obtained were decidedly in favour of the "new wet-collodion process" of that day. But the chief objection, if not the only one, to his process was the necessity for an abnormally strong silver bath—from 80 to 120 grains of silver nitrate to the ounce—which the strongly bromised collodion, aided by the low combining equivalent of bromine, involved. Otherwise, in point of quality of result and sensitiveness, Mr. Sutton's plates were at least quite equal to ordinary wet collodion.

Now, in utilising an emulsion in the manner we suggest, the difficulty of the strong bath is entirely overcome; for the bulk of the bromide of silver is formed in the collodion itself, with a comparatively small excess of soluble haloid to confer keeping qualities. The final sensitising, which also imparts the necessary stimulus of free silver to give rapidity, is done with a weak solution of silver

that, beyond being *clean*, requires none of the care and attention that the old silver bath did; and the resulting plates can be treated in every way as ordinary wet plates, if so desired, or, if preferred, as extra-sensitive dry plates.

(*To be continued.*)

AMERICAN NOTES AND NEWS.

The Heliochromoscope.—Mr. F. E. Ives writes to the editor of the *Photographic Times* that he has succeeded in constructing a heliochromoscope, in which the same triple positives used for projecting in the lantern are focussed upon the retina of the eye, as a single picture in the natural colours. "I can, therefore, now demonstrate the process at a minute's notice," says Mr. Ives, "sun or no sun."

New American Journals.—Still they come! the "they" in this case being the *Canadian Photographic Journal*, published at Toronto; and the *Pacific Coast Photographer*, issued from San Francisco. The last-named contains an article on plain paper prints, with one of which it is embellished, and a charming study it makes. This practical illustration of practical articles is a feature deserving of wide imitation.

Chicago Meeting of the Photographers' Association of America.—The Photographers' Association of America does not meeet this year; but the Executive Committee, at a recent meeting, have fixed upon Chicago as their place of meeting for 1893. The presumption is that there will be a good attendance, and, as several photographers from Europe will, doubtless, be visiting the World's Fair, a cosmopolitan fraternisation may be expected to take place on the occasion.

Insoluble Gelatine Prints.—The Editor of the *St. Louis and Canadian Photographer* acknowledges receipt of some gelatine prints that water will not affect, the paper being perfectly waterproof, and the "emulsion insoluble in boiling water." "It" (? the coated paper) "may be boiled continuously without in the least producing the slightest injury or softening of the emulsion. It does seem," remarks our contemporary, "as though perfection has been reached at last in a printing-out paper." But why boil gelatine prints, or employ water at such an abnormal temperature in their manipulation? and, consequently, where is the advantage of the insolubility?

"Looking Backward."—The veteran photographer, Abraham Bogardus, has been indulging in this fascinating recreation, and has some funny things to tell us. One Dr. Jacobson published the hypothesis *apropos* of a new paper (temp. 1860), that a special kind of hens were fed on nitrate of silver, and so produced, in an organic way, the albumenate of silver. . . . When the hens cease laying, their carcases were worked up the same as other silver residues! At or about the same time a Kentucky man claimed to have discovered photography in natural colours; "common salt" was recommended as a cure for blisters; "several new developers were introduced every month," and the "given away with a pound of tea" principle was in full blast in cheap photography. On the whole, excepting the above highly ingenious hypothesis, things are pretty much to-day as they were twenty-six years ago.
